Editorial Introduction

Robin Mackay

A new publication is obliged to justify its demands on the attention of a reader already besieged by countless specialist journals. This justification cannot appeal to the orgiastic logic of the filling of market 'niches'. With **Collapse** we have set out to achieve quite the opposite, aiming rather at a breadth and an openness found wanting.

That academic philosophy courts overspecialisation and a certain depression of the energy of thought is news to no-one. Whilst not wishing to denigrate the necessary and exacting work of scholarship, we wished to create a publication which communicated the passion for thought, and the excitement of thinking. The work we present here is unapologetically (and not unnecessarily)

COLLAPSE I, ed. R. Mackay (Oxford: Urbanomic, September 2007)
ISBN 978-0-9553087-0-4
http://www.urbanomic.com

demanding: we conceived **COLLAPSE** as providing a home for conceptual work in progress, with all the rough edges this might imply.

COLLAPSE is an experimental entity, in that it has no fixed agenda, no institutional ties, no partisan position: nevertheless it will be clear that neither the Editor nor the contributors regard this experimental status as the declaration of an open season for ludic enthusiasms. But as much as we did not wish merely to collate flights of philosophical whimsy, we also sought to avoid grounding ourselves in the 'application' of overgeneralised theoretical tropes to specific issues in pursuit of that most dismal of goals, 'relevance' to the 'contemporary' reader.

What was clear from the start was that the way forward lay in rigorously challenging philosophical thought by confronting it with conceptual production from elsewhere (and not in a presumptuous relation of 'application'): there is no doubt that philosophy only stays alive by maintaining porous boundaries with its outside–this does not detract at all from its specificity and value as a discipline.

If part of the problem with philosophy today lies in its professionalisation, we hope not to offend any of the contributors to this volume by saying that we consider every one of them to be *amateurs* in the true sense: dedicated and enthusiastic lovers of abstract thought, each engaged in adventures of ideas, each refusing to contain these adventures within strict formal or disciplinary boundaries. It should go without saying that, even if the two are rarely found in pure form, we favour *de jure* mad scientists with their bubbling conceptual cauldrons over career academics with their meticulously cautious conference papers.

Finally, we envisage each volume of **COLLAPSE** as the intersection, in a multi-dimensional space, of diverse lines of thought; the optimum circumstance would be if each reader picked up **COLLAPSE** on the strength of only one of the articles therein, the others being involuntarily absorbed as a kind of side-effect that would propogate the eccentric conjuncture by stealth, and spawn yet others.

A note on form: in several of the articles collected in **COLLAPSE I** we have used the interview form, and hope to do so in future. At its best it offers a medium in which the play of concepts takes a natural course and order of exposition, allowing the reader in turn to be swept up by its movement, and to reconstruct its underlying consistency at their leisure and with their own resources. Such an interview should read lightly whilst its spontaneous discursive complexity will be conducive to repeated readings.

* * *

Although we decided early on that eclecticism was neither to be scorned nor feared, a theme emerged, unbidden, during the long process of clarifying the journal's aims and collecting and commisioning work for this first volume. The working title was thus 'numerical materialism': an inquiry into the extent and nature of number's dominion over any philosophy calling itself a materialism; but also an inquiry into the materiality of number and numerical practices. Such a theme describes a realm exemplary in its liminal nature, not only connecting mathematics and philosophy but abutting onto every theoretical discourse with any aspiration to formal rationality.

We are privileged to have amongst our contributors ALAIN BADIOU, widely recognised as one of the most important philosophers alive today, and one who has consistently pursued this line of thought, often against the grain of philosophical orthodoxy. In our interview with Badiou we seek to clarify the consequences of a materialist thought which defines 'nature' through mathematics, determining 'history' in terms of its problematic 'outside'. We also succeed in provoking Badiou into addressing in detail some of the major objections raised against his doctrine, and into elaborating more precisely how he sees mathematics in its relation to other sciences. He also speaks of the new conceptual resources which his latest book *Logiques des mondes* brings to his ongoing work.

Although we have made clear our aspiration for the volume as a whole, this opening interview, together with the contributions of GREGORY CHAITIN and MATTHEW WATKINS particularly demonstrate the sort of conjunction we hope to effect with **COLLAPSE**: it would be difficult to find any other publication in which these could be found together. Here are three thinkers whose differences are not limited to their theoretical decisions but extend to their styles, and their respective conceptions of the nature of their subject. Despite this divergence, a number of common threads means that reading them together produces a combination that is more than the sum of its–already considerable–parts.

To say that GREGORY CHAITIN is well-known in his field would be to tell only half the truth: in fact Chaitin has for many years been something of a gleeful maverick. Whilst there can be no doubt as to his credentials as a 'serious mathematician' Chaitin not only enjoys communicating his mathematical discoveries to a wide an audience as possible, but he also never fails to draw from them (sometimes to the chagrin of fellow mathematicians) the most general speculative conclusions–just as did Leibniz, the very figure invoked in Chaitin's whirlwind review of 'Epistemology as Information Theory'.

Our interview with MATTHEW WATKINS is the very portrait of a thinker who defies categorisation. Watkins's singular talent at explaining complex concepts and his fluid, resolutely non-specialist speculative exploration of their significance makes of this interview a kind of conceptual cinematography, and made conducting it a genuine pleasure. As the engineer of a virtual agency which collects and catalyses material in an area of research which has only recently begun to condense, Watkins exemplifies well what was intended by the provocative subtitling of **COLLAPSE** as a 'Journal of Philosophical Research and Development': thought no longer takes place in the head–if it ever did–but involves the development of distributions and connections, a bio-techno-cognitive rhizome. Watkins also fiercely advocates the virtues of a marginal position which allows him the maximum space for reflection; as well as his substantive work we discuss the experiences formative of this conviction.

Badiou raises the question of the experiment: scientists continually set parameters and contexts for their experiments. Chaitin argues–and Watkins observations seem to support the thesis–that mathematics may also be, or may become, an experimental discipline. In NICK LAND's contribution, the meta-rational orthodoxies of experimental practice are themselves put to the test. Can the interrogation by an exotericised qabbalistics of the lexicographical element in which we are inscribed be denied the status of a science on the basis of utilitarian criteria? A delirious alphanumeric arithmetic…

The liberal media, with its indefatigable good intentions, has continually sought wholly to separate the ideology of terrorism from the tenets of a (poorly-defined) 'true' Islam. Whilst leaving no doubt as to the contingency of the circumstances, in his article for **COLLAPSE I** REZA NEGARASTANI describes the mutation, hybridisation and militarization of certain components of Islamic thought. The mongrel nature of this terrible conceptual assemblage makes it all the more remarkable that Negarastani ultimately refers it to a mathematical model; a veritable *mathesis* of fear.

The psychoanalyst and philosopher Lacan famously described his project as being that of a 'mathematisation of the unconscious'–a research programme that ended, if not in madness, certainly in an obscurity which endures to this day. In his 'Mathematics of Intensity' THOMAS DUZER picks up some of the threads of this project, inflecting it with an affirmative stance which militates against much of the psychoanalytical inheritance.

NICK BOSTROM heads an intriguing new research initiative where philosophical thought is put to work on issues formerly the quarry of inconsequential media panics and politicians platitudes; issues of truly unimaginable magnitude. Whilst such initiatives are no doubt to be applauded, we were interested to explore in our interview with Bostrom not only the work of his *Future of Humanity Institute* but also to ask whether philosophical thought must make compromises in order to break its traditional academic bonds.

KEITH TILFORD's graphical work draws on philosophical debates in poststructuralism: his 'crowd' drawings evoking especially the ongoing debates over the nature of multiplicity and individuation. 'INCOGNITUM' not only relates some intriguing details of numerical-cultural archaology, but has also compiled for us a selection of source materials in the shape of ABJAD diagrams. It was always our intention that **COLLAPSE** should not be purely textual, which makes these last two contributions are especially welcome.

It remains only to thank the contributors for their work and their patience during the assembling of this volume; and the reader for supporting this new venture.

In relating so expansively our aspirations for **COLLAPSE**, we do not dare to hope, nor do we mean to claim, that this first volume fulfills them all. At least the experiment is now underway; the Editor welcomes your responses and contributions for future volumes.

Robin Mackay,
Oxford, August 2006.

Philosophy, Sciences, Mathematics

Interview with Alain Badiou

Alain Badiou's radical equation of ontology–the traditionally philosophical 'account of being'–with mathematics claims to free philosophy for its contemporary task of interrogating the relation between the being which mathematics describes, and the events whose very 'impossibility' structures that being.

In the corollary distinction between the mere 'veridicality' of knowledge and the hazardous revolutionary decisions which found new truths, and in Badiou's account of the work of founding and remaining faithful to truth-procedures–in which humans finally become subjects–are rightly discerned a truly novel configuration of political thought.

However Badiou is also a penetrating and formidably knowledgeable philosopher of science and mathematics; and his meticulous dedication to following these disciplines' own 'truth procedures' has informed his work from the very beginning of his philosophical career through to 2006's Logiques des mondes[1].

Collapse asks Badiou to expand on the articulation of philosophy, mathematics and science his 'mathematical ontology' assumes; and what its consequences might be for the 'other' sciences.

Collapse: In an interview with Peter Hallward published in 1998, you say:

> In the last instance, physics, that is to say the theory of matter, is mathematical. It is mathematical because, *qua* theory of the most objectivised strata of the presented as such, it is concerned with being *qua* being in its mathematicity."[2]

If mathematics as science of being *qua* being provides scientific access to the presented, does that mean that mathematics provides the paradigm of 'scientificity'? And are we to understand that the degrees of objectification of what is presented ('being') correspond to degrees of mathematisation of scientific discourse?

Alain Badiou: It is undoubtedly more complicated than that. We must begin again from the distinction, which I have fully developed in *Logiques des Mondes*, between being and being-there, or between being and appearing. A world is structured not only by the pure multiples which appear in it (which 'are' in it), but by the logical organisation of that world, what I call its transcendental. So that every particular figure of what, in the 1998 interview, I called the 'presented', is the intersection of two formal rationalities. I propose to call "mathematical" ontological rationality–that rationality which concerns being *qua* being, that is, the indifferent multiple. Phenomenological rationality–that which concerns being *qua* appearing in a world–I call 'logical'.

---

[2] 'Politics and Philosophy: An Interview with Alain Badiou' *Angelaki: Journal of the Theoretical Humanities,* Vol.2, No.3, 1998, p. 127.

Of course, this logic is itself mathematicised, as is every logic today. But the distinction remains, a distinction whose criteria I have proposed in several of the texts included in *Court traité d'ontologie transitoire*[3]. We can say ultimately that a kind of objectification, a becoming-object, of pure being is inscribed within a singular correspondence between mathematics and logic–which ultimately means: between set-theory and Topos-theory. It being understood that these *Topos* realise a transcendental indexation of multiples to a sort of intensity evaluator, which in the current state of science, might be a complete Heyting algebra–for which English logicians have found the inspired name (since it effectively concerns the 'site' of being) of 'locale'.

So we cannot simply say that objectification is proportional to mathematicity. The new concept that I propose of what an object is ('object' is a key concept in *Logiques des mondes*) combines a purely mathematical element and a transcendental element which relates to the singularity of the world within which the object figures.

C: Readers of your work might be forgiven for suspecting that you hold physics in far higher regard than biology, that 'wild empiricism disguised as a science'[4].

4. Mathematics and Philosophy: The Grand Style and the Little Style' *Theoretical Writings*, eds. R. Brassier and A. Toscano, London: Continuum, 2004, p. 16.

There follow two further series of questions from this.

Firstly, concerning the relations between your ontological 'Platonism' (given that the latter effects an unexpected transformation of orthodox Platonism) and epistemological 'foundationalism' or 'reductionism'.

Secondly, the relation between your Platonic/Cartesian 'rationalism' and the 'naturalism' of contemporary cognitive science which inquires into the genesis of intelligence; an inquiry whose ultimate ambition is perhaps the reinscription of rationality itself (and hence of mathematical intelligence) within the domain of natural being (if not biology *stricto sensu*).

(1) If you advocate a 'foundationalist' view on the unity of 'Science', with the set-theoretical axiomatic at the base, then mathematical physics, chemistry, biology, etc. embedded one after another on successive strata according to a decreasing order of 'mathematicisation', do you think that this unity requires the reducibility of these sciences either to physics, or even to mathematics in the last instance?

And do you consider physical phenomena to be more 'fundamental' than biological phenomena because of these decreasing degrees of 'mathematicisability'? If so, don't you run the risk of making the coherence of science depend ultimately upon the reducibility of superstructures to an infrastructure, whether physical or mathematical? As you know, this idea of reduction remains highly problematic even within the natural sciences (for example the well-known difficulties concerning the reduction of 'emergent' properties).

Or is it rather that this 'foundationalist' and 'reductionist' perspective only holds for you within mathematics, that is to say for the relations between set-theory (or category-theory) and other mathematical domains?

(2) In *Being and Event*[5], you say that the thesis affirming the identity of mathematics and ontology is 'a thesis not about the world, but about discourse.'[6] No 'Pythagorism', then. On one hand, it might seem that this thesis claims to undo all the false problems engendered by the empiricist presupposition of a representational relation between discourse, or science, and reality; but, on the other, can we content ourselves merely with 'sublating' the difference between discourse and reality *within* a discourse (which, in Being and Event, remains 'metaontological' or philosophical rather than 'ontological' in the strict sense) without falling into absolute idealism?

How can we account for the position of mathematical and scientific 'discourse' given that, for you, the latter is not fundamentally linguistic, and so is not merely an artefact of cultural provenance; nor a natural and/or divine faculty, as intellectual intuition would be?

Don't the Darwinian revolution and the emergence of cognitive science as a natural science treating reason as a material phenomena–even if the 'materiality' in question is perhaps not simply neurobiological–oblige us at least to try to take account of this scientific and mathematical 'discursivity'?

---

[5] Alain Badiou, *L'être et l'événement.* Paris:Seuil, 1988. Translated by Oliver Feltham as *Being and Event.* London: Continuum , 2005.

[6] *Being and Event*, Introduction.

And in this regard, could it be that the 'sciences of complexity' or 'self-organisation', which try to apply mathematical modelling techniques to complex phenomena–vital, social, cultural, or even (above all) cognitive–could reduce the gap that you posit in *Being and Event* between the transitivity of natural sets, that is to say the homogeneity of nature, and the discontinuity of cultural situations, that is to say the heterogeneity of history? Wouldn't this ultimately be a way of assuring a maximum coherence between sciences and the science of being without the need for the impracticable ideal of reduction? Or does such a perspective seem far too Deleuzian-vitalist to you?

AB: First of all I would like to say that my perspective is not in the least 'foundationalist' or reductionist. From the ontological dimension of mathematics I draw no conclusion as to its superiority, its capacity to found the other sciences, or their status as the 'basis' for all scientificity. I say only that mathematics are the rational discourse on being *qua* being, or on the indifferent multiple thought as such.

Now, as you know, for me, a concept as general and essential for all thinking of the sciences as that of truth is not at all reducible to ontology as such. We must even admit that it explicitly contradicts certain of its formal axioms, just as Lucretius's clinamen contradicts the major axioms of atomist and materialist ontology.

In fact, I have often compared the absolute hazard of the event, subtracted as it is from the general determinations of being, to this clinamen, required for the assemblage of atoms to be thought as generic truth of worlds.

From all this, it follows simply that mathematics is a necessary formal dimension of all scientific discourse, if we understand by 'science', for the moment, the rational theory of those phenomena in the world which do not depend directly upon the conscious activity of man. Those phenomena pertaining, if you like, to the 'fossil argument', whose implacable rigour Quentin Meillassoux has deployed against every form of correlationism, or of the constitutive primacy of consciousness.[7] The mathematical exigency is formal, in so far as it supports, as to the intelligibility of these phenomena, their most abstract and most general strata, that which relates to their pure being, to their multiple composition. But, precisely, this strata cannot, in my view, represent that which is strongest and most 'true' in those sciences which are not purely mathematical. Take physics: the most elementary axioms of modern mathematical physics, let's say the principle of inertia as given by Galileo's formula, are not at all reducible to mathematical statements, even if they are obliged to take that form. A crucial point about physics is to present, to create concepts, so that they can be mathematically expressible, all the while retaining a relation to the world which means that they cannot be deduced from any mathematical corpus whatsoever. This is the case with the concept of uniform movement in the principle of inertia. Moreover, it is this irreducible worldly dimension which opens onto the possibility of experience, at the same time as mathematical formalisation guarantees the universality of experimental results, in the form of their always-possible repetition. All this, in my view, was thought in the most subtle and decisive fashion by Bachelard, and it is a great shame that anglophone epistemology has done such a thorough job of neglecting his work.

---

[7] *See* Quentin Meillassoux, *Après la finitude : Essai sur la nécessité de la contingence.* Paris:Seuil, 2006

So: I neither believe that physics is 'reducible' to mathematics, nor do I believe that mathematics 'founds' physics. Between the two, there is a rooting of concepts in a determinate world, which the experimental method designates and delimits, in a gesture which is of a transcendental nature.

Nor do I have any reason to think that physics 'founds' biology, still less that mathematics could do so. That biology, to say nothing of the 'human sciences', are still not sciences, does not result from the fact that they are not yet in a position to propose mathematical formalisms appropriate to experimentation. This formal deficiency is only a secondary symptom. The root of the problem is that their concepts are wholly insufficient, that they fail completely to present the phenomena concerned in the register of eternal truths.

In the case of biology, the possible founding intuitions all go back to Darwin. Mendel's experimental expertise opened another path, albeit one that is limited unless it is inscribed in the vast Darwinian innovation, which no-one to this day has succeeded in doing, unless it be in pre-conceptual approximations, purely rhetorical combinations of chance and necessity. The veritable conceptualisation of all this is yet to come. Naturally, there exist within this domain countless instances of knowledge, which are translated into remarkable technical skills, particularly in the medical field. But there is no science. To turn this domain into a science, some unforeseeable events would be required, a second post-Darwinian foundation, whose shape we cannot anticipate. In the meantime, we can say that there exist two sciences which cannot be hierarchised: ontology, or pure mathematics, and physics, the science of those worlds accessible to our experience.

As for cognitive science, I would like to make three remarks. Firstly, it is a programme rather than a theory. Even more so than biology, it is just a mass of facts and techniques, devoid of concepts or adequate formalisms. The truth is that we remain totally ignorant as to the real functioning of the brain. From what I know of the current state of research in cognitive science, I feel justified in concluding that, despite an impressive technical arsenal, it is no more advanced in its understanding of the phenomena than was Gall's phrenology, at the time when Hegel said the latter thought it had proved that 'spirit is a bone'. Today we think we have proved that thought is a neuron…Cognitive science is hardly further advanced than the theory of cerebral localisations in Broca, even if the active zones appear today in bright colours, displayed directly onto screens.

Secondly, that human intelligence should be a 'material' phenomenon is in my eyes a mere truism. What else could it be? I am, if this is the issue, completely monist. I do not think that any principle of being can 'double' indifferent multiplicities. What's more, I always speak of the 'human animal' when speaking about us, including even our most sophisticated cognitive activities.

And this leads me to the third point. Let me repeat: the fact that intelligence, as a faculty, is a material assemblage is self-evident and of no interest. However, that the question of truths relates to intelligence, or to the 'cognitive' in general, is a philosophical (not at all a scientific) statement, and a statement I believe to be completely false. *Qua* generic localised process, a truth is not at all reducible to anything whatsoever which takes the form of a human capacity or property, in the sense of the human animal.

To claim that it does is to remain within the legacy of Aristotelianism, Kantianism and analytic philosophy, which would locate truth in the form of judgment, with the latter in turn being a product of cognitive mechanisms. Whereas, as the other tradition saw–the Platonic, Cartesian, Hegelian tradition–a truth cannot be encapsulated in the form of judgment at all. It is a complex process, completely transcendent to the mere animal capacity of cognitive judgment. In my own conception, this process combines, ontologically, the possibility of generic multiplicities, and phenomenologically, the intraworldly constitution of post-evental bodies (in fact, of sheaves, in the modern algebraic sense, sheaves which 'rise' from the transcendental logic of worlds towards the objective multiplicities engaged in the procedure).

Since every truth is in-human, we can hardly hope to understand its genesis by poking around in the neurons of our brains!

I would like to add that to reduce thought to nature is in general a tautology, or a contradiction. If you understand by 'nature' the material state of all that is, it is a tautology: thought is certainly a part of that state. If you understand by 'nature' that which, precisely, pre-exists all thought, then it is a contradictory reduction.

C: Finally, two questions bearing principally on your *Le Nombre et les nombres*[8] . The distribution of prime numbers appears to be one of the irrecusable 'ontological' characteristics arising immediately from the construction of the natural numbers, but to this day it has proven resistant to our understanding. The Riemann Hypothesis suggests that complex numbers provide a refractory element through which it becomes possible to understand the prime distribution as a type of order. If we are to speak of ontology in this context, doesn't this oblige us to extend ontological dignity to complex numbers? But when you speak of number, you explicitly exclude complex numbers, along with quaternions, from the properly ontological domain[9].

---

[8] Alain Badiou, *Le Nombre et les nombres.* Paris:Seuil, 1990.

Historically, the affirmation of complex numbers *as* numbers, with all the consequences which followed, would seem indeed to be an example of a mathematical 'event'. Yet you reject it on the basis of its supposed intimate relation with geometry.

Now, even if (as is undoubtedly the case) it is precisely the geometrical and diagrammatic aspect of the complex plane which has inspired mathematicians and physicists, it is possible to conceive them independently of this usage. However, must we not consider the implication of physics, mathematics and geometry (or more generally, the diagram) from which the incontestable power of the complex plane arises?

It seems that the prime distribution is a profound mystery concealed within the apparently simple: the series of natural numbers. Alain Connes, among others, suggest that the apparent obscurity of the Riemann Hypothesis stems from as-yet uncomprehended aspects of the relation between simple addition and multiplication.[10]

---

[9] *Le Nombre et les nombres,* Ch. XVI, n.5

Meanwhile, recent work indicates astonishing consonances between the theoretical models of physics and Riemann's zeta function[11]. This seems to suggest, again, that the relation between mathematics and physics is not simply hierarchical, and furthermore, that the most fundamental ordering mechanisms in the universe do not necessarily coincide with our most analytically elegant accounts of order.

So where does the ontological begin and end? If we apply your criteria of ordinal linearity, don't we risk a premature foreclosure of ontology in the interests of elegance and philosophical taste, whilst rejecting the structures of the real–sometimes of an intimidating complexity, refractory to all intuition, such as Connes' adele–but which, from a point of view which we might call abstract-empirical, are imposed upon us by fundamental research in the domains of theoretical physics and mathematics?

AB: We must immediately correct a misinterpretation, perhaps owing to ambiguities in my writing, but no less massive for that: I have never thought that numbers were the highest form of ontological 'dignity'! Even less have I underestimated the mathematical–and thus ontological–importance of complex numbers, of diagrams, of topology! Absolutely not! I even argued with Deleuze

---

10,11. See 'Prime Evolution', in the current volume.

on this point, in our unpublished correspondence. He held that in 'reducing' multiplicities to sets, I reduced them to numbers. I replied to him that if numbers are all, in their being, sets, it would be quite wrong to conclude that all sets are numbers. The innate resources of set-theoretical multiplicity vastly exceed the concept of number.

As for complex numbers, I simply meant that they are exterior to the simple concept of number, which, in the sense I use it, includes order, comparison, and the notion of 'larger' and 'smaller', even when numbers are infinitely large or small. The fact that the field of complex numbers is not be an ordered field justifies this exclusion. Far from indicating a lack of dignity in complex numbers, this exclusion amounts to a further limiting of the properly numerical domain, and hence of further separating it from the ontological domain in its full extension. That complex numbers are sets, and hence thinkable as such in their being, is evident: it is a question, as we know, of the set of ordered pairs of real numbers.

I would like to add that when I say that the concept of number cannot be geometrical I am in no way–*heaven forbid!*–speaking against geometry! I have always indicated, from *Théorie du sujet*[12] onward, that the mathematical dialectic is that of algebra and topology, or, if one is Greek, arithmetic and geometry. And I know very well that today the most profound mathematics operates at the level of algebraic topology, a structural combination of the two great components of historical mathematics. And in fact this is the register frow which my new concepts ('transcendental', 'object', 'relation', 'evental field') draw their force. The results you mention which clarify number theory on the basis of the geometry of the complex plane or of highly sophisticated Analysis, perfectly illustrate this point.

---

[12] Alain Badiou, *Théorie du sujet.* Paris: Seuil, 1982.

But I do not speak of the mathematics of numbers in *Le Nombre…*, but only of what philosophy might draw from contemporary mathematics as to what a generic concept of Number might be.

Meanwhile, let us note that mathematicians always prefer, in arithmetic, an 'elementary' demonstration to one that is not. And what is an 'elementary' demonstration? An immanent demonstration, more or less directly derivable from the concept of whole number, and the rules of its operational domain.

In this regard, I agree with Connes: the heart of the question of prime numbers is that the operational dialectic of multiplication and addition, however perfectly clear from the axiomatic point of view, has yet to arrive at its true concept. There is there a deficiency of thought on the algebraic side. That this opacity might be overcome by the diagrammatic or geometrical aspect is quite possible.

My own approach clearly shows that what is opaque in numbers is not at all their definition, which, as I believe I have demonstrated, is very simple, even if you take the most gigantic numerical domain. What is obscure lies on the side of operations. Now, the concept of 'prime number' is a typically operational concept. To which we must add that it is largely negative (to not be divisible by any number other than itself or unity). I would be happy to propose the following heuristic principle: in pure mathematics, what is most difficult is always linked to a restriction (and thus to a negation) of operational capacities.

I will conclude by giving you a very simple account of physics' retroaction upon mathematics. There is nothing unusual about this: presented with the mathematical formalisation of concepts which only make sense in relation to a world which is not that of pure mathematics (concepts such as: 'movement', 'speed', 'light', and so on), physics requires of mathematics a sort of internal torsion, which introduces into its world (for it is a singular world) pure conceptual analogies with that which, initially, does not belong in this register. The clearest contemporary example is undoubtedly provided by quantum group algebra, a totally abstract and very exacting discipline, which would neither have existed, nor found its name, without quantum physics.

Translated by Robin Mackay and Ray Brassier

Epistemology as Information Theory: From Leibniz to Ω

Gregory Chaitin

The following text was originally delivered as the Alan Turing Lecture on Computing and Philosophy at E-CAP '05, the European Computing and Philosophy Conference, at Mälardalen University, Västerås, Sweden in June 2005.

INTRODUCTION

I am happy to be here with you enjoying the delicate Scandinavian summer; if we were a little farther north there wouldn't be any darkness at all. And I am especially delighted to be here delivering the Alan Turing Lecture. Turing's famous 1936 paper is an intellectual milestone that seems larger and more important with every passing year. People are not merely content to enjoy the beautiful summers in the far north, they also

COLLAPSE I, ed. R. Mackay (Oxford: Urbanomic, September 2007)
ISBN 978-0-9553087-0-4
http://www.urbanomic.com

want and need to understand, and so they create myths. In this part of the world those myths involve Thor and Odin and the other Norse gods. In this talk, I'm going to present another myth, what the French call a *système du monde*, a system of the world, a speculative metaphysics based on information and the computer.[1]

The previous century had logical positivism and all that emphasis on the philosophy of language, and completely shunned speculative metaphysics, but a number of us think that it is time to start again. There is an emerging digital philosophy and digital physics, a new metaphysics associated with names like Edward Fredkin and Stephen Wolfram and a handful of like-minded individuals, among whom I include myself. As far as I know the terms "digital philosophy" and "digital physics" were actually invented by Fredkin, and he has a large website with his papers and a draft of a book about this. Stephen Wolfram attracted a great deal of attention to the movement and stirred up quite a bit of controversy with his very large and idiosyncratic book on *A New Kind of Science*.

And I have my own book on the subject, in which I've attempted to wrap everything I know and care about into a single package. It's a small book, and amazingly enough it's going to be published by a major New York publisher a few months from now. This talk will be an overview of my book, which presents my own personal version of "digital philosophy," since each of us who works in this area has a different vision of this tentative, emerging world view. My book is called *Meta Math!*, which may not seem like a serious title, but it's actually a book intended for my professional colleagues as well as for the general public, the high-level, intellectual, thinking public.

---

[1] One reader's reaction (GDC): "Grand unified theories may be like myths, but surely there is a difference between scientific theory and any other narrative?" I would argue that a scientific narrative is more successful than the Norse myths because it explains what it explains more precisely and without having to postulate new gods all the time, i.e., it's a better "compression" (which will be my main point in this lecture; that's how you measure how successful a theory is).

"Digital philosophy" is actually a neo-Pythagorean vision of the world, it's just a new version of that. According to Pythagoras, all is number – and by number he means the positive integers, 1, 2, 3, . . . – and God is a mathematician. "Digital philosophy" updates this as follows: Now everything is made out of 0/1 bits, everything is digital software, and God is a computer programmer, not a mathematician! It will be interesting to see how well this vision of the world succeeds, and just how much of our experience and theorizing can be included or shoehorned within this new viewpoint.[2]

Let me return now to Turing's famous 1936 paper. This paper is usually remembered for inventing the programmable digital computer via a mathematical model, the Turing machine, and for discovering the extremely fundamental halting problem. Actually Turing's paper is called "On computable numbers, with an application to the *Entscheidungsproblem*," and by computable numbers Turing means "real" numbers, numbers like *e* or $\pi = 3.1415926...$ that are measured with infinite precision, and that can be computed with arbitrarily high precision, digit by digit without ever stopping, on a computer.

---

[2] Of course, a system of the world can only work by omitting everything that doesn't fit within its vision. The question is how much will fail to fit, and conversely, how many things will this vision be able to help us to understand. Remember, if one is wearing rose-colored glasses, everything seems pink. And as Picasso said, theories are lies that help us to see the truth. No theory is perfect, and it will be interesting to see how far this digital vision of the world will be able to go.

Why do I think that Turing's paper "On computable numbers" is so important? Well, in my opinion it's a paper on epistemology, because we only understand something if we can program it, as I will explain in more detail later. And it's a paper on physics, because what we can actually compute depends on the laws of physics in our particular universe and distinguishes it from other possible universes. And it's a paper on ontology, because it shows that some real numbers are uncomputable, which I shall argue calls into question their very existence, their mathematical and physical existence.[3]

To show how strange uncomputable real numbers can be, let me give a particularly illuminating example of one, which actually preceded Turing's 1936 paper. It's a very strange number that was invented in a 1927 paper by the French mathematician Emile Borel. Borel's number is sort of an anticipation, a partial anticipation, of Turing's 1936 paper, but that's only something that one can realize in retrospect. Borel presages Turing, which does not in any way lessen Turing's important contribution that so dramatically and sharply clarified all these vague ideas[4].

---

[3] You might exclaim (GDC), "You can't be saying that before Turing and the computer no one understood anything; that can't be right!" My response to this is that before Turing (and my theory) people could understand things, but they couldn't measure how well they understood them. Now you can measure that, in terms of the degree of compression that is achieved. I will explain this later at the beginning of the section on computer epistemology. Furthermore, programming something forces you to understand it better, it forces you to really understand it, since you are explaining it to a machine. That's sort of what happens when a student or a small child asks you what at first you take to be a stupid question, and then you realize that this question has in fact done you the favor of forcing you to formulate your ideas more clearly and perhaps even question some of your tacit assumptions.

Borel was interested in "constructive" mathematics, in what you can actually compute we would say nowadays. And he came up with an extremely strange non-constructive real number. You list all possible yes/no questions in French in an immense, an infinite list of all possibilities. This will be what mathematicians call a denumerable or a countable infinity of questions, because it can be put into a one-to-one correspondence with the list of positive integers 1, 2, 3, ... In other words, there will be a first question, a second question, a third question, and in general an Nth question.

You can imagine all the possible questions to be ordered by size, and within questions of the same size, in alphabetical order. More precisely, you consider all possible strings, all possible finite sequences of symbols in the French alphabet, including the blank so that you get words, and the period so that you have sentences. And you imagine filtering out all the garbage and being left only with grammatical yes/no questions in French. Later

---

[4] I learnt of Borel's number by reading Tasic's *Mathematics and the Roots of Postmodern Thought,* which also deals with many of the issues discussed here.

I will tell you in more detail how to actually do this. Anyway, for now imagine doing this, and so there will be a first question, a second question, an *N*th question.

And the *N*th digit or the *N*th bit after the decimal point of Borel's number answers the *N*th question: It will be a 0 if the answer is no, and it'll be a 1 if the answer is yes. So the binary expansion of Borel's number contains the answer to every possible yes/no question! It's like having an oracle, a Delphic oracle that will answer every yes/no question!

How is this possible?! Well, according to Borel, it isn't really possible, this can't be, it's totally unbelievable. This number is only a mathematical fantasy, it's not for real, it cannot claim a legitimate place in our ontology. Later I'll show you a modern version of Borel's number, my halting probability Ω. And I'll tell you why some contemporary physicists, real physicists, not mavericks, are moving in the direction of digital physics.

[Actually, to make Borel's number as real as possible, you have to avoid the problem of filtering out all the yes/no questions. And you have to use decimal digits, you can't use binary digits. You number all the possible finite strings of French symbols including blanks and periods, which is quite easy to do using a computer. Then the *N*th digit of Borel's number is 0 if the *N*th string of characters in French is ungrammatical and not proper French, it's 1 if it's grammatical, but not a yes/no question, it's 2 if it's a yes/no question that cannot be answered (e.g., "Is the answer to this question 'no' ?"), it's

3 if the answer is no, and it's 4 if the answer is yes.]

Geometrically a real number is the most straightforward thing in the world, it's just a point on a line. That's quite natural and intuitive. But *arithmetically*, that's another matter. The situation is quite different. From an arithmetical point of view reals are extremely problematical, they are fraught with difficulties!

Before discussing my Ω number, I want to return to the fundamental question of what does it mean to understand. How do we explain or comprehend something? What is a theory? How can we tell whether or not it's a successful theory? How can we measure how successful it is? Well, using the ideas of information and computation, that's not difficult to do, and the central idea can even be traced back to Leibniz's 1686 *Discours de métaphysique*.

COMPUTER EPISTEMOLOGY: WHAT IS A MATHEMATICAL OR SCIENTIFIC THEORY? HOW CAN WE JUDGE WHETHER IT WORKS OR NOT?

In Sections V and VI of his *Discourse on Metaphysics,* Leibniz asserts that God simultaneously maximizes the variety, diversity and richness of the world, and minimizes the conceptual complexity of the set of ideas that determine the world. And he points out that for any finite set of points there is always a mathematical equation that goes through them, in other words, a law that determines their positions. But if the points are chosen at random, that equation will be extremely complex.

This theme is taken up again in 1932 by Hermann Weyl in his book *The Open World* consisting of three lectures he gave at Yale University on the metaphysics of modern science. Weyl formulates Leibniz's crucial idea in the following extremely dramatic fashion: If one permits arbitrarily complex laws, then the concept of law becomes vacuous, because there is always a law! Then Weyl asks, how can we make more precise the distinction between mathematical simplicity and mathematical complexity? It seems to be very hard to do that. How can we measure this important parameter, without which it is impossible to distinguish between a successful theory and one that is completely unsuccessful?

This problem is taken up and I think satisfactorily resolved in the new mathematical theory I call *algorithmic information theory*. The epistemological model that is central to this theory is that a scientific or mathematical theory is a computer program for calculating the facts, and the smaller the program, the better. The complexity of your theory, of your law, is measured in bits of software:

program (bit string) → **Computer** → output (bit string)

theory → **Computer** → mathematical or scientific facts

Understanding is compression!

Now Leibniz's crucial observation can be formulated much more precisely. For any finite set of scientific or mathematical facts, there is always a theory that is exactly as complicated, exactly the same size in bits, as the facts themselves. (It just directly outputs them "as is," without doing any computation.) But that doesn't count, that doesn't enable us to distinguish between what can be comprehended and what cannot, because there is always a theory that is as complicated as what it explains. A theory, an explanation, is only successful to the extent to which it compresses the number of bits in the facts into a much smaller number of bits of theory. Understanding is compression, comprehension is compression! That's how we can tell the difference between real theories and *ad hoc* theories[5].

What can we do with this idea that an explanation has to be simpler than what it explains? Well, the most important application of these ideas that I have been able to find is in metamathematics, it's in discussing what mathematics can or cannot achieve. You simultaneously get an information-theoretic, computational perspective on Gödel's famous 1931 incompleteness theorem, and on Turing's famous 1936 halting problem. How?[6]

Here's how! These are my two favorite information-theoretic incompleteness results:

- You need an N -bit theory in order to be able to prove that a specific N-bit program is "elegant."

- You need an N-bit theory in order to be able to determine N bits of the numerical value, of the base-two binary expansion, of the halting probability Ω.

---

[5] By the way, Leibniz also mentions complexity in Section 7 of his *Principles of Nature and Grace*, where he asks the amazing question, "Why is there something rather than nothing? For nothing is simpler and easier than something."

[6] For an insightful treatment of Gödel as a philosopher, see Rebecca Goldstein's *Incompleteness*.

Let me explain.

What is an elegant program? It's a program with the property that no program written in the same programming language that produces the same output is smaller than it is. In other words, an elegant program is the most concise, the simplest, the best theory for its output. And there are infinitely many such programs, they can be arbitrarily big, because for any computational task there has to be at least one elegant program. (There may be several if there are ties, if there are several programs for the same output that have exactly the minimum possible number of bits.)

And what is the halting probability Ω? Well, it's defined to be the probability that a computer program generated at random, by choosing each of its bits using an independent toss of a fair coin, will eventually halt. Turing is interested in whether or not individual programs halt. I am interested in trying to prove what are the bits, what is the numerical value, of the halting probability Ω. By the way, the value of Ω depends on your particular choice of programming language, which I don't have time to discuss now. Ω is also equal to the result of summing 1/2 raised to powers which are the size in bits of every program that halts. In other words, each K-bit program that halts contributes 1/2K to Ω.

And what precisely do I mean by an N-bit mathematical theory? Well, I'm thinking of formal axiomatic theories, which are formulated using symbolic logic, not in any natural, human language. In such theories there are always a finite number of axioms and there are explicit rules for mechanically deducing consequences of the axioms, which are called theorems. An N-bit theory is one for which there is an N-bit program for systematically running through the tree of all possible proofs deducing all the consequences of the axioms, which are all the theorems in your formal theory. This is slow work, but in principle it can be done mechanically, that's what counts. David Hilbert believed that there had to be a single formal axiomatic theory for all of mathematics; that's just another way of stating that math is static and perfect and provides absolute truth.

Not only is this impossible, not only is Hilbert's dream impossible to achieve, but there are in fact an infinity of irreducible mathematical truths, mathematical truths for which essentially the only way to prove them is to add them as new axioms. My first example of such truths was determining elegant programs, and an even better example is provided by the bits of Ω. The bits of Ω are mathematical facts that are true for no reason (no reason simpler than themselves), and thus violate Leibniz's principle of sufficient reason, which states that if anything is true it has to be true for a reason.

In math the reason that something is true is called its proof. Why are the bits of Ω true for no reason, why can't you prove what their values are? Because, as Leibniz himself points out in Sections 33 to 35 of *The Monadology*, the essence of the notion of proof is that you prove a complicated assertion by analyzing it, by breaking it down until you reduce its truth to the truth of assertions that are so simple that they no longer require any proof (self-evident axioms). But if you cannot deduce the truth of something from any principle simpler than itself, then proofs become useless, because anything can be proven from principles that are equally complicated, e.g., by directly adding it as a new axiom without any proof. And this is exactly what happens with the bits of Ω.

In other words, the normal, Hilbertian view of math is that all of mathematical truth, an infinite number of truths, can be compressed into a finite number of axioms. But there are an infinity of mathematical truths that cannot be compressed at all, not one bit!

This is an amazing result, and I think that it has to have profound philosophical and practical implications. Let me try to tell you why.

On the one hand, it suggests that pure math is more like biology than it is like physics. In biology we deal with very complicated organisms and mechanisms, but in physics it is normally assumed that there has to be a theory of everything, a simple set of equations that would fit on a T-shirt and in principle explains the world, at least the physical world. But we have seen that the world of mathematical ideas has infinite complexity, it cannot be explained with any theory having a finite number of bits, which from a sufficiently abstract point of view seems much more like biology, the domain of the complex, than like physics, where simple equations reign supreme.

On the other hand, this amazing result suggests that even though math and physics are different, they may not be as different as most people think! I mean this in the following sense: In math you organize your computational experience, your lab is the computer, and in physics you organize physical experience and have real labs. But in both cases an explanation has to be simpler than what it explains, and in both cases there are sets of facts that cannot be explained, that are irreducible. Why? Well, in quantum physics it is assumed that there are phenomena that when measured are equally likely to give either of two answers (e.g., spin up, spin down) and that are inherently unpredictable and irreducible. And in pure math we have a similar example, which is provided by the individual bits in the binary expansion of the numerical value of the halting probability Ω. This suggests to me a quasi-empirical view of math, in which one is more willing to add new axioms that are not at all self-evident but that are justified pragmatically, i.e., by their fruitful consequences, just like a physicist would.

I have taken the term quasi-empirical from Lakatos. The collection of essays *New Directions in the Philosophy of Mathematics* edited by Tymoczko in my opinion pushes strongly in the direction of a quasi-empirical view of math, and it contains an essay by Lakatos proposing the term "quasi-empirical," as well as essays of my own and by a number of other people. Many of them may disagree with me, and I'm sure do, but I repeat, in my opinion all of these essays justify a quasi-empirical view of math, what I mean by quasi-empirical, which is somewhat different from what Lakatos originally meant, but is in quite the same spirit, I think.

In a two-volume work full of important mathematical examples, Borwein, Bailey and Girgensohn have argued that experimental mathematics is an extremely valuable research paradigm that should be openly acknowledged and indeed vigorously embraced. They do not go so far as to suggest that one should add new axioms whenever they are helpful, without bothering with proofs, but they are certainly going in that direction and nod approvingly at my attempts to provide some theoretical justification for their entire enterprise by arguing that math and physics are not that different.

In fact, since I began to espouse these heretical views in the early 1970's, largely to deaf ears, there have actually been several examples of such new pragmatically justified, non-self-evident axioms:

- the P ≠ NP hypothesis regarding the time complexity of computations,
- the axiom of projective determinacy in set theory, and
- increasing reliance on diverse unproved versions of the Riemann hypothesis regarding the distribution of the primes.

So people don't need to have theoretical justification; they just do whatever is needed to get the job done. . .

The only problem with this computational and information-theoretic epistemology that I've just outlined to you is that it's based on the computer, and there are uncomputable reals. So what do we do with contemporary physics which is full of partial differential equations and field theories, all of which are formulated in terms of real numbers, most of which are in fact uncomputable, as I'll now show. Well, it would be good to get rid of all that and convert to a digital physics. Might this in fact be possible?! I'll discuss that too.

COMPUTER ONTOLOGY:HOW REAL ARE REAL NUMBERS? WHAT IS THE WORLD MADE OF?

How did Turing prove that there are uncomputable reals in 1936? He did it like this. Recall that the possible texts in French are a countable or denumerable infinity and can be placed in an infinite list in which there is a first one, a second one, etc. Now let's do the same thing with all the possible computer programs (first you have to choose your programming language).

So there is a first program, a second program, etc. Every computable real can be calculated digit by digit by some program in this list of all possible programs. Write the numerical value of that real next to the programs that calculate it, and cross off the list all the programs that do not calculate an individual computable real. We have converted a list of programs into a list of computable reals, and no computable real is missing.

Next discard the integer parts of all these computable reals, and just keep the decimal expansions. Then put together a new real number by changing every digit on the diagonal of this list (this is called Cantor's diagonal method; it comes from set theory). So your new number's first digit differs from the first digit of the first computable real, its second digit differs from the second digit of the second computable real, its third digit differs from the third digit of the third computable real, and so forth and so on. So it can't be in the list of all computable reals and it has to be uncomputable. And that's Turing's uncomputable real number![7]

Actually, there is a much easier way to see that there are uncomputable reals by using ideas that go back to Emile Borel (again!). Technically, the argument that I'll now present uses what mathematicians call measure theory, which deals with probabilities. So let's just look at all the real numbers between 0 and 1. These correspond to points on a line, a line exactly one unit in length, whose leftmost point is the number 0 and whose rightmost point is the number 1. The total length of this line segment is of course exactly one unit. But I will now show you that all the computable reals in this line segment can be covered using intervals whose total length can be made as small as desired. In technical terms, the computable reals in the interval from 0 to 1 are a set of measure zero, they have zero probability.

How do you cover all the computable reals? Well, remember that list of all the computable reals that we just diagonalized over to get Turing's uncomputable real? This time let's cover the first computable real with an interval of size $\varepsilon/2$, let's cover the second computable real with an interval of size $\varepsilon/4$, and in general we'll cover the Nth computable real with an interval of size $\varepsilon/2^N$. The total length of all these intervals (which can conceivably overlap or fall partially outside the unit interval from 0 to 1), is exactly equal to ε, which can be made as small as we wish! In other words, there are arbitrarily small coverings, and the computable reals are therefore a set of measure zero, they have zero probability, they constitute an infinitesimal fraction of all the reals between 0 and 1. So if you pick a real at random between 0 and 1, with a uniform distribution of probability, it is infinitely unlikely, though possible, that you will get a computable real!

---

[7] Technical Note: Because of synonyms like .345999 . . . = .346000 . . . you should avoid having any 0 or 9 digits in Turing's number.

What disturbing news! Uncomputable reals are not the exception, they are the majority! How strange!

In fact, the situation is even worse than that. As Emile Borel points out on page 21 of his final book, *Les nombres inaccessibles* (1952), without making any reference to Turing, most individual reals are not even uniquely specifiable, they cannot even be named or pointed out, no matter how non-constructively, because of the limitations of human languages, which permit only a countable infinity of possible texts. The individually accessible or nameable reals are also a set of measure zero. Most reals are un-nameable, with probability one! I rediscovered this result of Borel's on my own in a slightly different context, in which things can be done a little more rigorously, which is when one is dealing with a formal axiomatic theory or an artificial formal language instead of a natural human language. That's how I present this idea in *Meta Math!*. So if most individual reals will forever escape us, why should we believe in them?! Well, you will say, because they have a pretty structure and are a nice theory, a nice game to play, with which I certainly agree, and also because they have important practical applications, they are needed in physics. Well, perhaps not! Perhaps physics can give up infinite precision reals! How? Why should physicists want to do that?

Because it turns out that there are actually many reasons for being skeptical about the reals, in classical physics, in quantum physics, and particularly in more speculative contemporary efforts to cobble together a theory of black holes and quantum gravity.

First of all, as my late colleague the physicist Rolf Landauer used to remind me, no physical measurement has ever achieved more than a small number of digits of precision, not more than, say, 15 or 20 digits at most, and such high-precision experiments are rare masterpieces of the experimenter's art and not at all easy to achieve.

This is only a practical limitation in classical physics. But in quantum physics it is a consequence of the Heisenberg uncertainty principle and wave-particle duality (de Broglie). According to quantum theory, the more accurately you try to measure something, the smaller the length scales you are trying to explore, the higher the energy you need (the formula describing this involves Planck's constant). That's why it is getting more and more expensive to build particle accelerators like the one at CERN and at Fermilab, and governments are running out of money to fund high-energy physics, leading to a paucity of new experimental data to inspire theoreticians.

Hopefully new physics will eventually emerge from astronomical observations of bizarre new astrophysical phenomena, since we have run out of money here on earth! In fact, currently some of the most interesting physical speculations involve the thermodynamics of black holes, massive concentrations of matter that seem to be lurking at the hearts of most galaxies. Work by Stephen Hawking and Jacob Bekenstein on the thermodynamics of black holes suggests that any physical system can contain only a finite amount of information, a finite number of bits whose possible maximum is determined by what is called the Bekenstein bound. Strangely enough, this bound on the number of bits grows as the surface area of the physical system, not as its volume, leading to the so-called "holographic" principle asserting that in some sense space is actually two-dimensional even though it appears to have three dimensions!

So perhaps continuity is an illusion, perhaps everything is really discrete. There is another argument against the continuum if you go down to what is called the Planck scale. At distances that extremely short our current physics breaks down because spontaneous fluctuations in the quantum vacuum should produce miniblack holes that completely tear spacetime apart. And that is not at all what we see happening around us. So perhaps distances that small do not exist.

Inspired by ideas like this, in addition to a priori metaphysical biases in favor of discreteness, a number of contemporary physicists have proposed building the world out of discrete information, out of bits. Some names that come to mind in this connection are John Wheeler, Anton Zeilinger, Gerard ’t Hooft, Lee Smolin, Seth Lloyd, Paola Zizzi, Jarmo Mäkelä and Ted Jacobson, who are real physicists. There is also more speculative work by a small cadre of cellular automata and computer enthusiasts including Edward Fredkin and Stephen Wolfram, whom I already mentioned, as well as Tommaso Toffoli, Norman Margolus, and others.

And there is also an increasing body of highly successful work on quantum computation and quantum information that is not at all speculative, it is just a fundamental reworking of standard 1920’s quantum mechanics. Whether or not quantum computers ever become practical, the workers in this highly popular field have clearly established that it is illuminating to study sub-atomic quantum systems in terms of how they process qubits of quantum information and how they perform computation with these qubits. These notions have shed completely new light on the behavior of quantum mechanical systems.

Furthermore, when dealing with complex systems such as those that occur in biology, thinking about information processing is also crucial. As I believe Seth Lloyd said, the most important thing in understanding a complex system is to determine how it represents information and how it processes that information, i.e., what kinds of computations are performed.

And how about the entire universe, can it be considered to be a computer? Yes, it certainly can, it is constantly computing its future state from its current state, it's constantly computing its own time-evolution! And as I believe Tom Toffoli pointed out, actual computers like your PC just hitch a ride on this universal computation!

So perhaps we are not doing violence to Nature by attempting to force her into a digital, computational framework. Perhaps she has been flirting with us, giving us hints all along, that she is really discrete, not continuous, hints that we choose not to hear, because we are so much in love and don't want her to change!

For more on this kind of new physics, see the books by Smolin and von Baeyer in the bibliography. Several more technical papers on this subject are also included there.

CONCLUSION

Let me now wrap this up and try to give you a present to take home, more precisely, a piece of homework. In extremely abstract terms, I would say that the problem is, as was emphasized by Ernst Mayr in his book *This is Biology,* that the current philosophy of science deals more with physics and mathematics than it does with biology. But let me try to put this in more concrete terms and connect it with the spine, with the central thread, of the ideas in this talk. To put it bluntly, a closed, static, eternal fixed view of math can no longer be sustained. As I try to illustrate with examples in my *Meta Math!* book, math actually advances by inventing new concepts, by completely changing the viewpoint. Here I emphasized new axioms, increased complexity, more information, but what really counts are new ideas, new concepts, new viewpoints. And that leads me to the crucial question, crucial for a proper open, dynamic, time-dependent view of mathematics,

"Where do new mathematical ideas come from?"

I repeat, math does not advance by mindlessly and mechanically grinding away deducing all the consequences of a fixed set of concepts and axioms, not at all! It advances with new concepts, new definitions, new perspectives, through revolutionary change, paradigm shifts, not just by hard work.

In fact, I believe that this is actually the central question in biology as well as in mathematics, it's the mystery of creation, of creativity: "Where do new mathematical and biological ideas come from?" "How do they emerge?"

Normally one equates a new biological idea with a new species, but in fact every time a child is born, that's actually a new idea incarnating; it's reinventing the notion of "human being," which changes constantly.

I have no idea how to answer this extremely important question; I wish I could. Maybe you will be able to do it. Just try! You might have to keep it cooking on a back burner while concentrating on other things, but don't give up! All it takes is a new idea! Somebody has to come up with it. Why not you?

APPENDIX: LEIBNIZ AND THE LAW

I am indebted to Professor Ugo Pagallo for explaining to me that Leibniz, whose ideas and their elaboration were the subject of my talk, is regarded as just as important in the field of law as he is in the fields of mathematics and philosophy.

The theme of my lecture was that if a law is arbitrarily complicated, then it is not a law; this idea was traced via Hermann Weyl back to Leibniz. In mathematics it leads to my Ω number and the surprising discovery of completely lawless regions of mathematics, areas in which there is absolutely no structure or pattern or way to understand what is happening.

The principle that an arbitrarily complicated law is not a law can also be interpreted with reference to the legal system. It is not a coincidence that the words "law" and "proof " and "evidence" are used in jurisprudence as well as in science and mathematics. In other words, the rule of law is equivalent to the rule of reason, but if a law is sufficiently complicated, then it can in fact be completely arbitrary and incomprehensible.

ACKNOWLEDGEMENTS

I wish to thank Gordana Dodig-Crnkovic for organizing E-CAP '05 and for inviting me to present the Turing lecture at E-CAP '05; also for stimulating discussions reflected in those footnotes that are marked with GDC. The remarks on biology are the product of a week spent in residence at Rockefeller University in Manhattan, June 2005; I thank Albert Libchaber for inviting me to give a series of lectures there to physicists and biologists. The appendix is the result of lectures to philosophy of law students April 2005 at the Universities of Padua, Bologna and Turin; I thank Ugo Pagallo for arranging this. Thanks too to Paola Zizzi for help with the physics references.

The Militarization of Peace: Absence of Terror or Terror of Absence?

Reza Negarestani

INTRODUCTION

This essay explores the rise of a new wave of terrorism which exploits its own dissolution, making a weapon of the doctrine of Taqiyya *or strategic (dis)simulation, dismantling the theatrical aspect of the battlefield and selecting civilians as primary targets and 'molecular battlefields'. This tendency threatens not only global civilian survival but the very horizon of survival or living (in its most basic, abstract sense) in general. It makes survival itself a field of exploitation for extremist terrorism.*

When militarization ceases to be an exclusively wartime process and to belong only on the battlefield, then even peace–the temporary gap, the blank space of unfriction between war machines and collective survival –can be militarized. This does not mean taking

COLLAPSE I, ed. R. Mackay (Oxford: Urbanomic, September 2007)
ISBN 978-0-9553087-0-4
http://www.urbanomic.com

advantage of peace as a temporary suspension which can be exploited, or as a depository in preparation for the militarization processes of future wars (who gathers the most forces when everyone else is resting?) Rather, and far more significantly, it means the endo-militarization of peace itself, wherein peace is directly used as a weapon, exploited as a new plane for invasion and insurgency, and for offensive strikes against enemy bases and/or their supportive lattices.

New modes of disseminating terror threaten the basic notions of survival in general, creating a generalized state of terror where death hangs over, regulates, every moment that is lived. Such *necrocracy* is the goal of heretical Islamic agencies of Terror such as *Jama'at-e Takfir*[1] and its *Takfiri* agents – a militant *Jihadi* movement believing in the absolute excommunication of infidels (*Takfir* originally means excommunication). These agencies have inspired a new wave of militant religious extremists and other obscure terrorist groups who are exploiting the endo-militarization of peace as a new mode of warfare. This new mode of warfare is one whose tactical lines are not aligned with (or configured by) the plane of conflict and visible military friction (battlefields, terrains for guerilla warfare, street-wars, etc.); Its tactical lines do not have the localizability which is a prerequisite for direct conflict and military formation; They are not positioned to cut, block or replace each other depending upon their different tendencies, transorientations and alignments; Their operations have a wholly oblique relation to the dynamic incompatibility which provides the basis for, and the matrix of, militarized conflictual engagement.

---

[1] *Jama'at-e Takfir* (The Society of Excommunication) influenced by Qutb's Muslim Brotherhood emerged in Egypt as a fundamentalist group in the 1960s with Islamic fundamentalist and militant inclinations (the former being similar to extremist Salafism) enmeshed through decentralized and stealth operation networks. The group advocates any military course of action (whether armed battles or not) against Jews, Christians, apostate or moderate Muslims, in order to restore (or return to) the primal unity of the Islamic world order.

A *Takfiri* engages as a shadow terrorist in *White War* – the endo-militarization of peace, a state of hypercamouflage (best defined as *complete* and consequently symmetrical overlap between two entities on a mereotopological[2] plane). In this war, the cover of camouflage can never be penetrated or disrupted, and the defensive employment of camouflage (best mapped as *partial* overlap between two or more entities on a logical plane) is replaced by a wholly novel, highly offensive deployment, the space of hypercamouflage. The *Takfiri*'s favoured mode of warfare is to program a new type of tactical line which totally blends with the enemy's lines in such a configuration that it introduces radical instability and eventually violent fissions into the system from within. This happens in such a way that not only does recovery become impossible, but in addition any corrective or restorative initiative is ineluctably turned into a military subversion: like a chemotherapy gone awry or an excessive scarring in which healing and the process of epithalization, in the absence of a wound, corrode the organ in the form of fibroproliferation (a scarring process which transforms the local injury of the wound into a pervasive metastatic scarring), resulting in eventual lysis and decomposition. In attempting defence, the enemy can only necrotize and dissolve itself.

---

[2] Mereotopology is a theory of topological relationships between parts and boundaries. See Barry Smith, "Mereotopology: a theory of parts and boundaries", in *Data & Knowledge Engineering*, Volume 20, Issue 3 (November 1996), Elsevier Science Publishers, pp. 287 - 303.

DEEP TERROR: THE DECLINE OF THE ENEMY AND THE RISE OF OBSCURE ALLIES.

Abdu-Salam Faraj's manifesto *Jihad: The Absent Obligation* – in which malevolent political pragmatics and tactical perversion are planted carefully in a context of evangelistic justification and theo-tyrannical apologetics – is a case study of this mode of warfare: White War or the militarization of peace, comprising aggressive *hyper-camouflage* as its primary engine.

Hypercamouflage aims to pursue to even the most attenuated extreme, a fighting and a surviving alongside the enemy. It invariably indicates a total withdrawal from the perception of friends and a dissolution into the enemy: the rebirth of a new foe.

In his book, Takfiri cultist and terrorist Faraj crafts a fetishized form of *Jihad*, suggesting that the incinerating head of *Jihad* must be introduced to everyone, to any entity, regardless of their position, geographic location, ethnicity, regardless of the relevance or otherwise of that entity to *Jihad*, Islam or infidelity – *Jihad* as a universal sweeping movement. The original title of the book, which in translation has become simplified into *Jihad: The Absent Obligation*, is *Jahad: Fariezato Ghaebata* (or *Jihad: Fariezeh Ghaeb*). *Fariezeh* means holy duty, but not a subjectively authoritarian duty as is demanded by *Huda* (Allah's guidance), the 'utter submission' (*Islam*) to Allah. *Ghaeb* means absent, but in Islamic texts and especially Shia books, it encompasses a huge hermeneutic potentiality which 'absence' cannot hope to translate; in fact, rather than mere absence *Ghaeb* indicates latent potentiality, in the sense, for instance, of the latent period of inactivity of a virus. This latency is to be distinguished from the actualized and visible, which is liable to distortion and change: Imam Mahdi (the 12th Imam and the harbinger of *Qiyamah*, the Islamic Apocalypse) is absent (*Ghaeb*) but affects Islam and its followers more than anything *actually* present; Mahdi represents a potentiality that never ceases to affect. In Faraj's book, however, this definition, which is a fundamental theological and eschatological platform for his argument, becomes eclipsed by a message at once more accessible and more divergent from this original meaning: *Jihad* becomes a holy responsibility which is not present.

Faraj's book adds a new twist to the tactics of heretical religious extremists such as the cult of *Takfiri*: the distortion and alteration of '*Taqiyya*' (*Taghieh*) from its original defensive and devout function in the dawn of Islam. Rather than a strategic (dis)simulation – a justified concealment of true beliefs in situations where harm or death will definitely be encountered if the true beliefs are declared[3] (the wider meaning of *Taqiyya* being "to avoid or shun any kind of danger.") it is reinterpreted as a silent and fluid military infiltration, a course of action which forms one of the elemental components of fetishized Jihadism.

Faraj's take on *Taqiyya* departs entirely from what in the dawn of Islam originated as a defensive or protective inclination, an evasive tactic. In *The Absent Obligation*, *Taqiyya* is reconstituted as a type of strategic simulation or dissimulation, in the name of a hostile politics of offence. However, both in its traditional form and in this new weaponized form, *Taqiyya* is strongly bound to the notion of survival. In the traditional sense this is so simply because by taking *Taqiyya* the believer survives in difficult circumstances. But in militarized *Taqiyya*, survival is transformed into a sort of highly-charged parasitical endurance which inherently threatens the catalysis of all those whose survival is afforded more easily. Survival becomes as risky as a contagious terminal illness. Faraj insists that *Jihad* cannot be separated from *Taqiyya*. Whereas crusades transgress boundaries in order to retake the holy lands, in Islamic tradition *Jihad* intrinsically cannot be transgressive; it must merely *defend* the holy lands, and Islamic properties (which are not necessarily associated with geopolitical agencies). But as revivalist figures like Sayyid Qutb[4] and Shukri Ahmad Mustafa have twisted the entire panorama of Islamic thought, heretical Islam's defence of its 'properties' has become a *universal* 'defence' encompassing massive waves of acentric assault and a military subversion pervaded by a complex tendency towards the exclusion of all beings except for the monopolistic wasteland of the Divine (the Desert). "The earth itself moves towards Allah by submitting itself to the 'exterior' Will of Allah; or in other words, is not Earth a part and property of Islam (utter submission to Allah) which must be defended?": Qutb turns the issue inside out, all of theological thought becoming ravaged by monopolistic dictatorship and monomania. The Earth itself becomes a part of the defensive politics of *Jihad*[5]. Ahmad Mustafa, one of the theorists of the original *Takfiri* cult, also suggests that "We are returning to Islam", and that this Grand Return involves surrendering to the Desert of the Divine: this is not a reactionary response to the infidels, he insists, but merely the path to Islam, which is condemned and met with overreaction by the rest of the world – a world whose entire horizon, moreover, is in fact already a part of Islam. Mustafa's discussion takes a twisted monotheism and heretically embeds it within the foundations of Islam – creating a retrograde movement back to a self-deluding, romantically-imagined phantasy of the original Islam. To this notion of *Jihad* which seeks to retake the Earth as a part of Islam (Earth as a part of the universe is on the route of *utter submission – Islam –* to Allah) Faraj cunningly adds the politics of *Taqiyya.* As Faraj himself confesses, this (re)taking of the Earth is not an easy task; hence the necessity of being armed with *Taqiyya* and its potential for insinuation and diffusion within the systems and peoples of non-Islamic countries.

---

[3] "The believers never ally themselves with the disbelievers, instead of the believers. Whoever does this is exiled from GOD. Exempted are those who are forced to do this to avoid persecution. GOD alerts you that you shall revere Him alone. To GOD is the ultimate destiny." (The Quran 3:28)

---

[4] Sayyid Qutb (1906-1966), one of the central theorists of Islamic Revivalism and an inspiration for later extremists such as Faraj; his *Ma'alim fi-l-Tariq* (Milestones) is perhaps the first theoretical work of modern extremist Islamism, integrating pragmatic exhortations with self-centered politico-religious doctrines. On Qutb, see Paul Berman's analysis of terrorism inspired by the caliph's militarism and heretical Islamic revivalism: Berman, P. (2004) *Terror and Liberalism*, W. W. Norton & Company.

[5] "The Islamic civilization can take various forms in its material and organizational structure, but the principles and values on which it is based are eternal and unchangeable. These are: the worship of God alone, the foundation of human relationships on the belief in the Unity of God, the supremacy of the humanity of man over material things, the development of human values and the control of animalistic desires, respect for the family, *the assumption of the vice-regency of God on earth according to His guidance and instruction, and in all affairs of this vice-regency, the rule of God's law (Shari'a) and the way of life prescribed by Him ...*" (Sayyid Qutb, *Milestones*); see Qutb (1991) *Milestones*, American Trust Publications, p. 286.

According to Faraj the new doctrines of weaponized *Taqiyya* can be enumerated as follows:

(1) *TAQIYYA* AS THE DISSOLUTION OF YOURSELF AND THE OTHER: *Taqiyya* becomes a politics aimed at drawing the war out of the battlefield (In this extremist *Jihad*, war must be put to work everywhere but the battlefield; war is external to the conventional battlefield. 'War is not a theater, you infidels', Faraj shouts). This is to be achieved by introducing the *Jihadi* entities to civilians and all other seemingly militarily irrelevant political economic or cultural entities, by blending with the crowd which exists far from the front lines. 'Towards the real omnipresence

of war which progressively effaces the theatrical platitude of the battlefield', the doctrine of Terror voluntarily transforms itself into a sinister movement of utter self-dissolution. The use of *Taqiyya* as a (para)offensive politics, however, is not the invention of Faraj, or the *Takfiri* cult, or even of Wahhabi extremists. It can be traced back to Hassan i-Sabah but it is not the invention of Hassan either (although he improved and strictly militarized it). The sole credit for *Taqiyya* as a (para)offensive *polytics* aimed at blending with the crowd (as opposed to *Taqiyya* as a dissimulating tool for evading harm, as devised in the early days of Islam) belongs to Abdullah ibn Maimun or Maymun (and his *Batiniyya* cult, one of the underground heretical Islamic societies and subversive movements which he founded and which later turned into *Isma'ilie* sects directed by Hassan i-Sabah): Maimun, the Persian occultist, political saboteur and conspiracist who undermined the reign of caliphs in Egypt (where the *Takfiri* cult also originated together with such influential figures such as Qutb, Mustafa, *et al.*) with a sudden debacle, and prepared the region for his ambiguous and mysterious allies *Al Fatemids* (*Fatemion*) who later became the most enthusiastic enemies of the caliphs and their conventional modes of militarism. Faraj, following closely Ibn Maymun's politics, suggests that *Taqiyya* should not be merely a deception, a hiding tactic; it should consist of seeking the highest degree of participation with infidels, with their civilians: "if they take drugs we must do the same, if they take part in every type of sexual activity we must drive those activities to the point of excess", etc. The *Jihadi* extremist must become as one with the civilians of what are called 'hardcore infidels'.

(2) *TAQIYYA* AS A (PARA)OFFENSIVE MILITARIZATION OF CIVILIANS: In reference to Faraj's politics of *Taqiyya* as an inseparable element of *Jihad*, the French counter-terrorist expert and President of the Paris-based World Observatory of Terrorism, Ronald Jacquard, brilliantly points out that a '*Takfiri* under *Taqiyya*' is himself a primed bomb, whether or not he ever sees action (is involved in a mission). When a *Takfiri* becomes as one with ordinary civilians – no longer dissimulating but moving and behaving like a true, unfaithful civilian in every aspect of his or her public and private life – then the weapon begins autonomously to be activated from the other side; the government (of a foreign non-Islamic country, for example) itself begins to filter, purge and hunt down its own civilians, curtailing their rights, confining them to economic, social and political quarantine to isolate or even purge the disease and its potential hosts at the same time. Each individual is potentially a *Takfiri* cell or niche, a site of infestation, a primary military target. So that the most offensive, active phase of a *Takfiri*'s life is not when he or she is on a high-profile mission like 9/11, but rather when he or she becomes a mere civilian, totally unarmed and dissociated from any line of command. A *Takfiri* levels himself with everyone and consequently levels everyone with himself; when it comes to hunting a *Takfiri*,

one ineluctably ends up exterminating non-military entities, far away from the battlefield, in the heart of one's own land.

(3) *TAQIYYA* AS A TRIGGER FOR WHITE WAR: *Taqiyya* unbalances the entire conventional dynamics between war machines, a dynamics which sees them clash with, hunt, and consume each other. This process of unbalancing does not serve to shift the battle along the diametric axis of 'victory or defeat', but rather to unbalance the communicative links between two tactical modes: *active military lines* at one pole and *virally latent (un)tactical lines* at the other. The *Takfiri* shuts down all his military potential, tactically 'dies' (not even being camouflaged anymore), and later is resurrected again in 'his' true form. The *Takfiri* war machines of extremist *Jihad* operate on transient and divergent tactical lines. As a result, they cannot be reached or communicated with: communication which is the prerequisite for the clash between war machines and entropically-based military conflicts, mechanisms considered by Deleuze and Guattari as the processes which fabricate the very machinery and space of War.

(4) TAQIYYA AS A DESERTIFICATION TOOL: Giving fetishized *Jihad* an epidemically omnipresent machinery, *Taqiyya* allows Faraj to open a new era in the imagining of mechanisms of extinction, sabotage and eradication fueled by the pyromaniac aspects of heresy and dangerously romantic theo-tyranny. Faraj discusses the fact that 'their' (he rarely even names his so-called enemies: the

US) military war machine relies heavily on the *megadeath principle* or as they put it DEATH FROM ABOVE (Overkill, Killing drones, High-tech airplanes, smart bombs, "Shock and Awe", MOAB (Mother of All Bombs), invisible missiles descending from nowhere). Faraj presents a *Takfiri* alternative to this megadeath machinery[6]: He discusses a new doctrine of hypercamouflaged terror which he calls 'Dieback machinery', a term borrowed from botany and agriculture[7]. What he defines as 'Dieback' can be applied to an entire 'civilization just as well as a Tree or any arborescent mode of collectivity': in order to introduce a Tree to extinction, a *Takfiri* terrorist never interferes with the roots, attempting to uproot the whole tree, as this would merely remove the taproot, leaving rootlets and other root parts in the soil that would eventually grow and give rise to many new trees. The terrorist or *Jihadi* extremist launches a *dieback* disease against the tree: to be precise, he starts to extinguish the most expendable and smallest leaves growing at the top of the tree and its branchlets, and continues his work to the rest of leaves, without damaging the main trunk or roots. By destroying leaves from top to bottom and by marring branchlets, the tree will wither: excommunicated and dejected, the tree will eventually be entirely incapacitated and will start to *(over)react autophagically* and *allergically* to the artificial dereliction effected by the dieback disease. *Taqiyya* provides *Takfiri*s with ample opportunity to use this dieback machinery, starting from the leaves (civilians or what they call 'expendable entities') and branchlets (small organizations, etc.), ultimately rendering the tree obsolete without ever having launched any direct attack against its main organs.

---

[6] Questions of escalation and diffusion of conflict in time and space are of massive significance for both the western military campaign and Jihadism's terror-skirmishes. While Jihadism works with diffusion in its off-battlefield conflicts (through its petropolitical contamination of the global politico-economic systems, its reckless use of weaponized *Taqiyya*, working with strategy rather than tactics and contagious communication rather than transgression), the western techno-capitalism maintains a escalating position in the battlefield, a position connected to the propulsive body of techno-capitalism, its tactical precision and suprmacy. However, both of them share a common tendency in conflict: turning human agencies into molecular battlefields / warmachines; for Jihadism this molecularization of warriors takes an epidemically dispersive form: mainly through *Taqiyya*'s para-offensive plane and for the western front, it turns into re-nomadization (in the Deleuze-Guattarian sense of nomadic warmachines) of the State's army and miniaturization of an entire army and its specifications on and through the body of each soldier.

[7] A disease of plants characterized by the gradual dying of the young shoots starting at the tips and progressing to the larger branches.

When a tree is infected by dieback disease, only leaves and branches are destroyed; however, lacking leaves and branchlets, the tree gradually becomes prone (overexposed) to environmental factors and all of its systems become locked into malfunctioning programs, lowering its immune system and consuming the tree from within. Various stages in the dieback of a civilization would be: paranoia; lack of investment; civilians as primary targets for both fronts; dereliction. All of which result in a reactionary response from the infected tree which, rather than aiding recovery, is self-destructive. In a system this self-destruction (or malfunctioning self-recovery) can be defined as breakdown of the mechanisms responsible for self-tolerance, and the induction of an immune response against components of the self. Such a cataclysm leads to the reprogramming of the (immune) system to damage the self.

A '*Takfiri* under *Taqiyya*', then, is nothing but a civilian. By destroying himself and civilians he can apply the dieback mechanism to a system. Weaponized *Taqiyya* is not directly connected to the dieback mechanism; but it is a way in which a *Takfiri* can shift the role of *Taqiyya* from mere camouflage to a powerful logistical plane on which (para)offensive tactics and strategies can be converged and amplified. When a *Takfiri* extremist goes under *Taqiyya* he embeds his sabotaging mechanisms within civilians, *uses civilians as back-doors*. A *Takfiri* under *Taqiyya* is transposed from being a key operational figure in his own army to being a civilian; at this point, *Taqiyya* actually gains access not to important targets but to ordinary civilians (the primary tactic of the dieback mechanism), allowing the *Takfiri* an opportunity to effectively confound and twist all diagrams and maps which allow a civilian to be distinguished from a terrorist. Through this back-door, a *Takfiri* can both damage civilians (or expendable entities of the tree, as they are regarded) more effectively on a massive scale, and turn their protection systems against them by assimilating them within itself and by being assimilated by them.

The original doctrines of the *Takfiri* cult originate from the teachings of Qutb and Shukri Ahmad Mustafa. Faraj, under the influence of the doctrine of '*Takfir wal'Hijra*'

(Excommunication and Exodus) – imitation of the prophet who left Mecca and the House of Allah to live in a *purified desert* purged from any manifestation of idolatry – enunciates a new vision of desert and desertification alien to the conventional image of the Desert familiar to socio-political dynamics, and western social dynamics in particular. On several different levels, this desert encompasses all radical trends of Islam, from the ceaseless exteriority of Allah to Man, to desert as the mere functional plane of submission to this radical exteriority (Allah who will be never disclosed), to the original desert-nomadic ingredients of *Jihad*. A desert nomad does not migrate, as it is minimally under the influence of climatic factors; it burrows tunnels of its own, making its own niches within the desert, crossing the dimensions of holey and smooth spaces, exploiting and betraying them equally. Scorpions are burrowers not architects, they do not build upon compositions of solid and void, nor do they move restlessly, they devour volumes and snatch spaces; for them the holey space is not merely a dwelling place, a place to reside (a niche for occupation) but more than that, it is the Abode of War (*dâr al-harb*), the holey space of unselective hunting. Mustafa hysterically introduced the machinery and the notion of the desert into all threads of his thought to such a degree that his cult was mockingly called 'The desert flogging society'. It is rather ironic to reveal Mustafa's real profession: he was a very talented agronomist.

Take a Russian forest bordering the tundra, whose trees are emptied of life because they have been hit by black-rot and winter dieback; In a *Takfiri* sense, deserted trees are no different from a desert without trees: dieback purifies, desertifies, the infidel organism, bringing the Earth within the compass of the utter desolation of the Desert of the Divine.

In the wake of militarized *Taqiyya*, the *Takfiri* is no longer the problem; it is the original civilians of the country, rather than immigrants, who pose a terminal security threat. There is no more radical act of war than fighting in molecularized and expendable battlefields whose potentiality for conducting conflict has already been incapacitated.

LOGICAL INVESTIGATION OF HYPERCAMOUFLAGE VS. NOMADIC CONFLICT.

"In the past one took a more *defensive* attitude," wrote Koch, referring to miasma theory. "We have now moved away from this defensive point of view and have seized the *offensive* ... We must be prepared, first, to detect the infectious material easily and with certainty, and second, to destroy it" (Koch 1903, 8, 10). For Koch, taking the offensive meant actively seeking the parasites not only in those obviously ill but also those "suspected" of carrying them (*die Verdächtigen*) and in "the apparently healthy."[8]

Every warmachine or tactical line occupies a niche (whether in wartime or peace), a space through which it can move, feed and function; it is not only defined by the distinctive properties of a tactical line or warmachine but also by its enemies, the incompatible dynamism of other tactical lines, types of predators, the exposure to environmental factors, its threshold for receiving data from the environment, the types of data it receives and its propinquity to what it pursues or probes (there is a common misunderstanding that attributes solid or crisp boundaries to niches; but niches are assembled wherever an entity economizes a portion of its environment and survives / functions in that economized space[9]). At a given time *t*, the entity *r* occupies a unique[10] address (or set of addresses) as $r_t(x)$; its movement can be simplistically expressed in terms of the niches it occupies at successive intervals of time. This address is encoded and set apart by the niche which the warmachine or tactical line occupies.

---

[8] Otis, L. (1999) *Membranes: Metaphors of Invasion in Nineteenth-Century Literature, Science and Politics*, The Johns Hopkins University Press, pp. 34-35

The functions of a niche are not merely disjunctive and exclusive (for example, directing competitions *i.e.* selective movements which result in exclusion of other portions of the environment or lines of movement) but also connective/conjunctive. In fact niches mobilize their occupant entities with their characteristic types of dynamism, associating them with other niches based on the affordance necessary for following a tendency or a plane as well as sharing it with other niches and their inhabitants. The programming of its niche is the first basic operation of engineering or recomposing an entity. Therefore the significance of investigating niches or niche types (rather than token niches or occupants) progressively increases with the development and emergence of new dynamic lines, power formations, traffic spaces and planes of communicative conjunctions. The State and its grid of dominance identify the movements of an entity (*r*) in a niche (whether quantitative – metron-based [measurable, scalable] – or qualitative) by the series of addresses it authenticates and registers as it travels:

---

[9] In fact, some monitoring systems basically concentrate on niches with fiat and vague boundaries to screen and guide their occupants (tenants). Air traffic control systems constantly analyze the volume of protected or restricted airspace – defining a circumspace or the volume enclosing a flying object – for collision avoidance, alert systems and translocations of aircrafts. The volume of protected airspace is a modified term for niche in traffic management, a simulation of the niche that exists in flying or migrating birds.

[10] This uniqueness is characterized by the definitive properties / qualities that the address attributes to an entity in space-time but to have an address does not mean to be the exclusive owner of it.

$$r\ (x_1,x_2,x_3,\ldots,x_n)$$

For the State, the dynamism geared by warmachines, the way that each warmachine perpetuates its itinerant line, can only be traced and numerically tagged through the logic of boundaries, the programming of dwelling/accommodating systems and (dis)locations that the State is able to monitor by monitoring niches and their dynamic addresses. By means of overseeing boundaries through which entities pass, investigating the temporal effects on (or alteration of) the forces of territoriality that moving entities leave behind, their types of localization, and their behaviors towards mereologic economy (the economy of the whole), the State can fabricate a *cogito* (a non-human cognition) not only to realize but also to classify the movement of entities and the dynamism of warmachines whose immoderate nomadic itineracy means that they cannot be directly apprehended or sensed by the State. This is the *cogito* required for appropriation of warmachines under the State's military protocols and forms. Bound to (semi-)rigid segmentarity, dynamic boundaries, affordance-based connections and static or dynamic localizations (or more accurately, in-place and outside-place localizations), the State examines the dynamic space of each entity and its activities – those activities corresponding to its functional, territorial and mereologic regions – not only to read the characteristics of an entity but also to locate it on (or according to the proximity of the entity to) its grid of dominance. The State and all configurations of Survival Economy track entities through the niche(s) that they inhabit or populate. For the State's military Overwatch, investigating and tracing the niche is the primary and central task; the itinerant line of an entity or a warmachine, its communications and functional traits are all deciphered by scanning the niche the warmachine occupies and its type. The advanced reading-machines of the State are even capable of extracting the quiddity of a warmachine or an entity by analyzing the specifications of the niche which is intrinsically bound to affordance, dynamic forces of boundaries, and eco-logical principles.

However, as niches are connective entities (entity-as-event in a Deleuzian sense); they do not exclusively belong to one entity or one tenant. Multiple entities can share one niche and niches can form nested niches (territorial forces diminish – but never disappear – in grouping bonds) linking to each other, being connected in various modes. Modes of connection between niches are divided for the most part into two asymmetrical correlations:

a. Abutment (**A**)

b. Overlap (**O**)

In the Deleuze-Guattari model of the nomadic warmachine, the warmachines are external to the State's effective boundary, restlessly eroding it, gnawing at the consolidated borders of the State. Logical modeling of the interactions between the exterior nomadic warmachines and the State is complicated mainly by the following problems:

(a) Both the State and the warmachine retain a relative

---

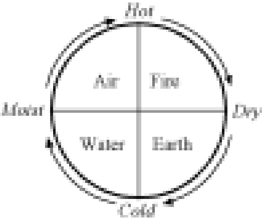
11. Affordance is an economical network (in the sense that it is connective and reciprocal) by which openness can be exploited as a groundwork for survival, accommodation, dwelling and regulating communication.

The term affordance as used here diverges in certain respects from the original term coined by James Jerome Gibson (based on the works of Ingarden, Brentano, et al.) in his eco-cognitive studies. The regulations by which an entity can maintain its dynamic position (in a whole, *i.e.* mereologic address) and survive in its environing horizon originate from a deeply meshed economic-based network of interactions, connections and regulative participations, all knitted on mutual affordability between the entity and its environment. Whole can only survive when entities can afford each other, every type of openness on mereologic levels is demarcated by mutual affordability 'between' entities. Affordance does not exclusively belong to one pole of the economical communication but is distributed between at least two mereologic entities. 'I am open to you as long as I can afford you' otherwise: (a) you must be repulsed (b) attracted by being regulated and appropriated (c) partly filtered (d) I should appropriate myself to 'accommodate' you. Therefore, the plane of being open to is intrinsically constructed on affordance or economical affordability/communication. Through affordance, openness cannot escape movement to each other (each dynamic on its own plane of tacticity) which makes the State's militarized machines and nomadic warmachines slippery entities with a progressive displaceability increasing as attacks and counter-attacks are escalated at the borders of the State.

(b) The rise of the clandestine State, that opens itself to the nomadic warmachines to either absorb them within its military formations by continuous contacts with nomadic warmachines (such contacts are essentially bound to contaminative potentials for both the State and the nomads) or reinvents nomadic warmachines as its mercenaries, dynamic lines for extending the State beyond its border, a new dynamic boundary providing the State with the opportunity of accommodating (colonizing?) or economically affording (affordance[11]) the Outside instead of being cracked open by the Outside.

---

survivalist and economical regulations; it mainly works as the dynamic capacitator of Whole. Possibly the most elucidating (yet simplified) 'model' of affordance is Aristotle's Tetrasomia (Rotation of the Elements).



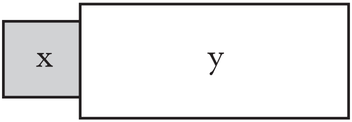
The rotational movement between elements sustains a refining dynamism for the whole. Each phase of rotation is based on dynamic metrons (measures, scales) and affordance (here, economical openness or mutual affordability) between elements. Elements are open to each other either diametrically or diagonally, but they can

Focusing on the spatiogeographic aspect of the warmachine (necessarily interconnected with its affective aspect) – or, more precisely, investigating a mereotopological model of the nomadic warmachine and the State through their distinctive but general mode of connection which can be grasped as abutment or external connection – might be the primary task for diagramming the affect-space and the lines of movement generated between concrete nomadism and the State. This modelling, both spatiogeographic and mereotopological (and thus necessarily indicating an immanent affect space) of the nomadic warmachine and its positioning relative to the State's boundary elucidates the processes at work in the emergence of anomalous nomadic states (as in the case of the 'guerilla-state' and its connection with ethnonationalism in Iran or the Bedouin nomad-tribes and their strong but ambiguous bonds with the Saudi government in

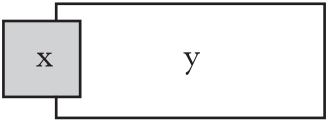
---

never entirely overlap or radically communicate with each other; they need a mid-state to form rotational nexuses and maintain their Wholeness. These mid-states are valid only in a particular location of the whole rotational panorama; although they provide the system with a propulsive *polemikos* or cyclic dynamism, they function locally (as a result of the elements' affordability to each other and, at the same time, to the whole system of Tetrasomia). For example, Earth and Water need Menstruum (living mud) to communicate. This living mud is a communicational entity but also a dynamic boundary which transforms/appropriates the earth and water before opening them to each other; it can only work locally between earth and water and not at any other location in the model of Tetrasomia. The Whole uses these economical communications to consolidate itself and to afford Life (to survive).

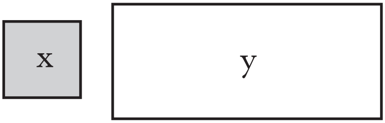
"I assume that affordances are not simply phenomenal qualities of subjective experience (tertiary qualities, dynamic and physiognomic properties, exc.). I also assume that they are not simply the physical properties of things as now conceived by physical science. Instead, they are ecological, in the sense that they are properties of the environment relative to an animal. These assumptions are novel, and need to be discussed." (J. J. Gibson)



Abutment



Partial Overlap



Disjunction

Fig. 1

Saudi Arabia) as well as the increasing risk for nomadic warmachines engaging clandestine states or states with an obscure boundary.

POSITIONING OF THE NOMADIC WARMACHINE ON A MEREOTOPOLOGICAL PLANE.

Abutment (fig. 1) is an external connection, with minimum trade between niches or entities (the least contagious connection, given its tendency towards dissociation). It is demarcated by its intermediacy before partial overlapping and after disjunction, by its tangential contact and boundary overlap.

What was once the frontier of the State's defence is continuously eroded by the reckless tidal or updrift movements of nomadic warmachines. The operational significance of this mode of connection (Abutment) has been significantly decreased with the emergence of symbiotic and manipulative warmachines and covert militarization processes on the one hand, and advanced reformations of the State towards the accommodation (or colonizing) of the Outside on the other. The latter are rooted both in the introduction of territorial climatologic factors[12] to the dynamism of nomad-packs and in the development new modes of survival. Now, the state knows well how to save its foundations, even if it means assembling spaces susceptible to the erosion of nomadic warmachines, attracting or diverting the incoming nomadic incursions to specified and preprogrammed regions to protect its critical terrains and vulnerable mechanisms, or transforming its macropolitics into a *viable* micropolitics which are open at one end and grounded at the other end.

---

[12] On Climate and Nomadology: Following the so-called Hydraulic and Agricultural Revolution in Iran (similar to that which Wittfogel associated with the Chinese Empire, as well as Homer-Dixon's more recent theories on Hydropolitics), during the reign of Mohammad Reza Pahlavi (Shah), an hydraulic plan – highly recommended by American consultants – was developed and proposed as a catalyst for economic development in Iran; one of multiple objectives of this plan was to solve the problem of nomads in Iran. Apart from putting into effect a program of hydraulic restructuring of the diverse geography of Iran (a geography with innate potential for the forging of diversifying lines of nomadic movement), one of the stratagems of this hydropolitical program of reform was to originate a system for monitoring and domesticating Iranian nomads who played key roles in resistance against the centre or induced geopolitical disintegration of the State's territory via their ethnonationalistic movements. The plan was neither a method for drawing the eastern and central nomads to the governing center nor a project for forcibly accommodating them in a sedentary sphere through the monopolization of water-networks and direct military impositions. Rather, it suggested accompanying them, interlocking with them and replacing their dynamism with the State's fluxional lines of tactics, its dynamic boundary and territorial forces. The project's objective was to construct a soft climate (klima: zone) or a

In a typified connection C_τ, abutment can be mapped on the Euclidean plane R as:

$$A_\tau(x,y) =_{df} C_\tau(x, y) \wedge \neg O_\tau(x,y) \quad \text{(x abuts y)}$$

(Where O_τ is a typified boundary overlap.)

Or let T = {X, cl} be a topological space, where X is the set of points and cl is the closure operator. Let *I* be any index set that includes 0. The domain, *D*, of a Layered Model is a nonempty set of ordered pairs $x_i = \langle x,i \rangle$ where $\emptyset \neq x \subseteq X$ and $i \in I$. (x_i will be used for $\langle x,i \rangle$).

$$A(x_i,y_i) =: x \cap y = \emptyset \,\&\, (cl(x) \cap y \neq \emptyset \text{ or } x \cap cl(y) \neq \emptyset) \quad \text{(abuts)}$$

Since Abutment links entities on a tangential plane (*confinium*), the state can effectively resist any arriving onrush of nomadic warmachines on this mode of connection with minimum attrition damage on its critical interior (the plane of logistics and lines of command). In fact, clandestine states seek to channel all the cumulative damage induced by nomadic warmachines (as the postulate of the obtrusive danger) on this mode of connection. This is achieved by deflecting any fundamentally contagious, manipulating and undermining threat towards distributive and recoverable eroding processes; these latter can even be programmed to transport the State out of its rigid segmentarity and despotic bond with territoriality, prolonging the survival of the state in a fluxional mode in a manner of an abrasive machine of the *fluvius* (river) that erodes solidity in order to transport it by the dynamic conservative vector fields of sedimentary processes – capturing fecundity and irrigation in detrition. With warmachines tirelessly gnawing at the State's *textum*, incising and liquidating its crisp boundaries, the State begins to leak out, but this does not only express the collapse of the State but also the dangerous exposure of the nomadic warmachine to the underlying grid on which the State is assembled and which holds its interwoven space, a network of grounding processes, mechanisms of territorial regulation and economic repression.

The Installation of the operational cutting-edge of nomadic warmachines on the State in the absence of any ungrounding machineries (which incapacitate the dominant grounding, territorializing and moderating functions of the State) is a similar case to that of the premature line of deterritorialization which facilitates either the unconventional establishment of new immunologically-enhanced States or a suicidal flight. Persian history, over a long period of time (from the Achaemenians to the Qajar dynasty (1779-1925), more than two thousand years), narrates such a continuous conversion of nomadic forces into State forces, before being again replaced by another nomadic population (cyclic nomadic uprisings against the ruling regime with a nomadic germ-cell still active but privatized as the State's elite, versatile military institution). Such premature nomadic detritions of the

State have progressively given rise to more powerful (in terms of gravity, immunity and parasitic resistance) yet more unstable States, causing politico-economic poverty; inclination towards being colonized by other States; lack of an autonomous nervous system and polarization of different populations without the possibility of positive diversity; constant vulnerability to schisms, civil-wars, and ethnonationalistic fault lines deleterious to an entire country or geopolitical sphere.

When abrasion processes of nomadic warmachines continue to hold their eroding positions – essentially characterized by transporting dynamism of friction (*tactionis*) and the process of mass-wastage – over a long duration on the borders of the state, hyper-active territorial nexuses between the State and nomadic warmachines emerge, increase and expand. Once such nexuses are established (boundary overlap), the underlying ground economy of the State (or its territorial forces), its entities and even the State's internal machineries directly leak out into the space traversed by nomadic warmachines, to such a degree that they pervade the nomadic space and

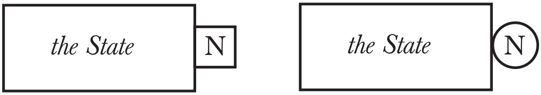


Fig. 2. Boundary Overlap with the State (diagrammed as a square) and Nomadic Domestication (left), Tangential Contact (diagramed as a circle) and Nomadic Effectivity (right)

turn it into a dynamic extension of the State[13]. In this case, the State's functional or territorial entities cannot be effectively enveloped and carried away by nomadic warmachines (as in the case of tangential contact) anymore. They cannot be cut from the State's grid of dominance, liberated and radically dispersed to the Outside (fig. 2).

The hazardous contact of nomadic warmachines with the State, exposing them to the state's regulating functional/territorial spheres, can eventually lead to the emergence of a nomadic-state on the one hand and an ethnonationalistic nomadism (identical to the State's patriotic policies) on the other. Probably one of the most significant examples of such anomalies triggered by the over-exposure of nomadic warmachines to the State is that found throughout Persian history.

(b) Overlap:

If, in a simplified approach, P stands for parthood and O for overlap:

$$O_{\tau}(x,y) =_{df} \exists z(P(z,x) \wedge P(z,y))$$

And

$$Oxy{=}{:}\exists z(Pzx \mathbin{\&} Pzy) \text{ (}x\text{ and }y\text{ overlap)}$$

Then the following Axioms apply:

$$\textbf{AP1}\ P(x,y) \leftrightarrow \forall z(O(z,x) \rightarrow O(z,y))$$

$$\textbf{AP2}\ \exists x(\phi(x)) \rightarrow \exists x \forall y(O(x,y) \leftrightarrow \exists z(\phi(z) \wedge O(z,y)))$$

Any participation (either *methexis* as survival-based participation or base-participation) happens through overlapping connections. Therefore, the majority of

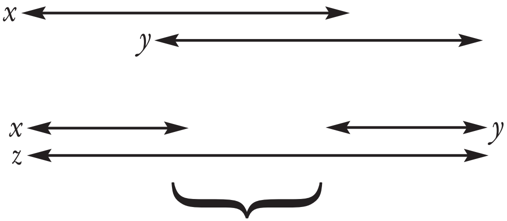
Fig. 3. Modes of Connection
(Abutment and Overlap)

combined connections (Tangential, Parthood, Interior, etc.) are effectuated by different possibilities educed by overlap between entities. Overlap draws lines of coincidence between two events or entities by specifying an address that two entities partly or completely share in a spatio-temporal or a functional region. Both the State's appropriations and counter-state *insurgencies* happen through this mode of connection. Whilst it is exploitable by the State and by affordance, this does not mean that 'overlap' cannot also be the main source of insurgency – it is the connection-domain through which warmachines leave their border-eroding externality and directly arrive at the State's grid, either to be specialized by the State apparatus and turn into *military formations* or to be reinvented as contagious, endo-symbiotic and parasitic entities *coinciding* with the State and its machineries and consequently discovering a wide array of clandestine



Not overlapped:
The zone of evacuation and withdrawal from the camouflaged position or the escape-route.

Fig. 4. Partial overlap and its interval relations in Camouflage:
(1) Between two entities; (2) Between two entities and the third entity

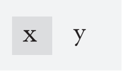
and manipulative functions.

On a more technical plane, all camouflage exploitations are essentially consistent because they all involve the use of 'overlap' (or, more accurately, coincidence, as the question of overlap between entities here is the question of overlapping niches which these entities occupy[14]). Furthermore, they turn it from a mode of connection into a politically-operational positioning that violates both the symmetry of a niche with the address it writes (programs) for an entity and the divisors (events, entities, etc.) which separate and discriminate the addresses or niches of two entities in space-time coordinates. However, this violation (that necessitates the activation of camouflage) cannot remain durable and unchanged, because predatory/military camouflages always employ partial overlap, with a part constantly accessible as 'not camouflaged' (either belonging to the camouflaged entity x or the entity which it should be overlapping *i.e.* y[15] [See

---

[14] Two entities will be said to overlap when they share parts in common: two entities coincide when they occupy *overlapping* regions of space.

[15] An example of the *not camouflaged* part (not overlapped) solely belonging to *x* or *y:* When the 'not camouflaged' part merely belongs to *y* (in a typified connection):



x internally overlaps *y*. When:

$IO_\tau(x,y) =_{df} \exists z\ (IP_\tau(z,x) \wedge IP_\tau(z,y))$

x is an interior part of *y*, and when

$IP_\tau(x,y) =_{df} P_\tau(x,y) \wedge \neg\, TP_\tau(x,y)$ and

$TP_\tau(x,y) =_{df} P_\tau(x,y) \wedge \exists z\ (A_\tau(z,x) \wedge A_\tau(z,y))$, *x* is a tangential part of *y* fig. 4]). This not only makes tracing and handling of the camouflaged entity possible on a tactical level but also provides the camouflaged entity with an escape-route or a space for instant evacuation and withdrawal from the camouflaged position. (An escape-route can also be unlocked when an entity *z* – a third party – connects to both *x* and *y* with different overlapping positions for each one (See fig. 4); here, the escape is channeled through another camouflage, a new camouflaged participation extracted neither from *x* nor from *y*.) This 'not camouflaged' or 'not overlapped' part inhibits the camouflage from being durable or constantly undetected, but also makes camouflage controllable; the camouflaged entity can move out of the camouflage at any moment.

All types of camouflage draw a disruptive function from the overlapped part (which mainly occurs on a fragmented level) by conducting the address or niche of another entity (for example, the prey) to the camouflaged entity (hunter) and consequently disrupting the mereologic (part-whole) correlations at work with regard to what should be camouflaged, making it temporally and partly untraceable, camouflaged. Such disruptions (which generally target a reference-point or a reference-link by which an entity is detected) can produce cognitive-glitches as well as the subversion of some specific environing bonds that pass through both the camouflaged entity and its object (its prey). Motion camouflage uses a particular type of tactical dynamism (in cases where the prey is also in motion, the movement of the shadower or the camouflaged predator moves on the path of a chaotic pursuit; the movement can be modeled by projecting its pursuit curves onto the Rössler attractor) or dynamic overlap to disrupt (i.e. shadow) its distance and displacements from the prey (the shadowed) by moving on a path that connects it to a fixed point (used by the shadowed as a reference-point – a constant unit vector) while the motion by the target is met by the motion from the aggressor. In motion camouflage, then, the shadower remains stationary for the target. In the most common military camouflage – disguise by covering objects (soldiers, vehicles, artilleries, launch pads, etc.) – with Disruptive Pattern Materials, disruption happens through surface modifications of a camouflaged object on which the visual sensory organ focuses as a reference-link between different types of surface patterns in its surrounding space, resulting in the ignoring of the object as a part of the safe environment. Invisibility (as a retreat

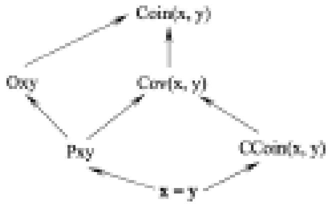


Fig. 5. If **Coin** stands for coincidence, **O** for overlap, **P** for part, **Cov** for cover and **CCoin** for complete coincidence.

from visual sensors), too, employs and modifies partial overlap as an occlusion by obscuring surfaces, interiorizing, positioning the camouflaged (cloaked) entity where boundaries intersect (obscuring boundaries), etc. The primary drawback of the invisible warmachine is the danger of being traced by semiotic regimes of the State which are more obsessed with what is missed than with what exists.

As the result of partial overlap, all disruptions and subversions of mereologic bonds are subjected to eventual disclosure; and each time a camouflage is spotted, it progressively loses its potential; any entity using such a camouflage will be more prone to detection and forestalling counter-measures than it usually is; this is a symptom of the holistic connections between partial overlap and 'localization' which has not been functionally incapacitated and spatially effaced yet. This is why camouflage is rarely implemented as a primary action or an offensive tactic but mostly as a logistic process or a mis-ordering transitional space between different tactical and operational lines. Transient characteristics and stringent operational restrictions obstruct radical weaponization of camouflage.

A *Takfiri* under *Taqiyya* (Islamic hypercamouflage) does not occupy a niche to replace another entity, or dwell as a hidden agent; he pushes the connection with his environment toward a complete overlap, an unbroken field of connection and correspondence, a complete coincidence with its target, *i.e.* a complete overlapping of its niche with the niche of its target. He entirely overlaps his prey and its niche and thus remains silent.

$$\mathrm{Coin}(x,y) \leftrightarrow \exists z(\mathrm{Cov}(z,x)\ \&\ \mathrm{Cov}(z,y))$$

(*x* and *y* coincide if and only if there is some *z* that is covered by both *x* and *y*; *z* standing here for niche. While **Cov** is a transitive and reflexive relation, **Coin** is symmetrical and reflexive. The relation of coincidence is of course broader than that of overlap, since there are pairs of coincident objects or even processes that do not share parts. The same question of relation arises for a *Takfiri* under *Taqiyya* and a civilian.)

For a *Takfiri* under *Taqiyya*, occupation is neither a military goal nor a tactic; since occupation is *exclusive localization* tethered to the mappings of co-localization and parts-whole connectedness – that is to say, the despotism of Whole – the occupier is vulnerable to environmental forces; it can be easily distinguished, located, isolated and finally terminated *i.e.* undone at the minimum attrition cost of its environment and surroundings. Where occupation is bound to visibly militant and escalating modes of warfare and exclusion, weaponized *Taqiyya* is maliciously diffusive. In mereologics (the discourse of part-whole modes of connectedness) we would call the positioning of *Taqiyya complete overlap*: the *Takfiri* constitutes a sinister survivalism whose basic function is to extinguish survival itself. In complete overlap (see Fig. 6), every region, function or part of the hypercamouflaged entity or predator, the '*Takfiri* under *Taqiyya*' (X) can correspond with its identical region, function or part of the prey/host/civilian (Y). Therefore if every *x* (part or function of X) homologizes its corresponding *y* (part or function of Y) or more precisely, if every *x* corresponds with its *y* 'on all levels' then every function of X (the tactical movement of the *Takfiri* under *Taqiyya*, or hypercamouflaged predator) can be transferred to Y and they mutually fulfill each other.

$$x=y \leftrightarrow \forall z(Oxz \leftrightarrow Oyz)$$

(Any two members of the domain that overlap the same entities are identical.)

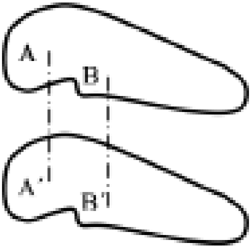

Fig. 6. Complete overlap and symmetric fulfillment
(Symmetry: Let $\boldsymbol{S}$ be the symbol for symmetry where $\boldsymbol{n}$ is an integer, $\boldsymbol{d}$ is the class descriptor and $\mathit{comp}\boldsymbol{d}$ is the complement of $\boldsymbol{d}$: $\boldsymbol{S} = \{\boldsymbol{n}(\boldsymbol{d}) \wedge \mathit{comp}\boldsymbol{d}\}$)

But the most horrific dimension of this arrangement is revealed when the process is reversed: if every *x* fulfills its corresponding *y*, then by way of the 'exact connecting-corresponding' space that complete overlap and complete coincidence ($\mathbf{CCoin}(x_i, y_i) =: x = y$)[16] provides, every *y* (i.e.

---

[16] Complete coincidence can be expressed in terms of covering (**Cov**):
$\mathbf{Ccoin}(x,y) \leftrightarrow \mathbf{Cov}(x,y)\ \&\ \mathbf{Cov}(y,x)$
(*x* and *y* completely coincide if and only if *y* covers *x* and *x* covers *y*)

every function or positioning of the prey Y, which would comprise for the most part normal survival functions and ordinary individual or social activities) can be transferred to its corresponding *x* and eventually fulfill it too. By seizing any *y*, a corresponding *x* is triggered and covertly unleashed; and since we are dealing with complete overlap, the very *survival and communication* of Y deploys, activates and fulfills the menacing body of X, the *Takfiri* under *taqiyya*. On the one hand, the survival of the prey/host/civilian thoroughly agrees with the sinister enthusiasm of the terrorist; and on the other hand, peace is generally conceived as the state of collective survival. So that the survival of both the terrorist and the civilian yields nothing but the (interminable?) endo-militarization of peace, a global threat against civilians, the rise of White War and the threat that, fuelled by the infinite thirst of heretical Jihadism, the contagion of war might expand unchecked, even to fill the immensely significant horizon of survival and *living* in general.

Now that the survival of Y or the host/civilian (together with its communication and modes of connection through and with its *environment*) fulfills the political and military body of the '*Takfiri* under *Taqiyya*', the mere existence of the civilian is weaponized against both itself and the immune system of the system that accommodates and protects it to such a degree that auto-phagic overreaction looms as the only logical solution for the system. It is the military culmination of Taqiyya to deduce irrevocable insanity from the minimum essential logic required for basic survival.

EXEGETICAL CONCLUSION.

"The trends explored here will obviously be decided 'on the battlefield' - but that increasingly means everywhere. The centrality of hypercamouflage to Jihadi strategy is already having immense consequences, inducing a wave of 'retro-militarization' in State war machines, where 'teeth' flow back down the 'tail' in a process without obvious terminus (short of the fanging-up of the entire social body).

Saddam Hussein's auto-disassembly of his own war machine in the interests of a latent insurgency exemplifies this trend from one side, whilst the moves to harden up US logistics formations through armoring of vehicles and combat training for all personnel complements it from the other.

Human rights concerns about killings of civilians could relevantly be extended from the empirical level to that of the transcendental, where the eradication in principle of all civilian populations is taking place. The very concept of 'the civilian' is becoming distinctly dated. (Virilio's analysis – despite betraying a somewhat antiquated perspective through terms such as 'endocolonization' – seems to have anticipated this trend).

The US is especially interesting because it remains a 'peripheral' (even 'third world') society in certain respects, marked by a low domestic index of State monopolization of violence, thus allowing retro-militarization from the State pole to connect with an endogenous paramilitarism already rooted in the 'civilian' population (armed vigilantism and militia movements). As far as militias are concerned, the world ain't seen nothing yet."[17]

COLLAPSE VOLUME I Erratum

. p76 Note 12 should continue as follows:

…The project's objective was to construct a soft climate (klima: zone) or a zone of hydraulic conductivity (corresponding to the State's Hydropolitics) which would autonomously accommodate nomads, making them move through itself, and thereby ease the whole process of monitoring, domesticating and tracking nomads. This climate being finally transformed into a tremendously dynamic network of anti-nomadic movements, would employ its hydraulic head to configure nomadic dynamism according to the State's geo-politics, economic convergence and military dynamism (an accessible space for the State's military entities especially during insurgencies); the State was seeking to breed its own territorializing (rather than territorialized) nomadologic lines. This climate was actually to consist of 'artificial rivers' which were supposed to be distributed over the country. The work of construction of these rivers was to be undertaken over a period of years, in a country that has always suffered from a lack of water in its central and eastern regions. Such fluid, rich and dynamic zones or hydraulic lines (for instance rivers and their tributaries) spread over the country would gradually attract (on the pattern of gravity) nomads, rendering a preferable but precisely mapped climate for their migration; a climate which would actually be an autarkic monitoring machine rendering its inhabitants predictable and expanding a fluid domesticating sphere for the Iranian nomads.

Prime Evolution

Interview with Matthew Watkins

Matthew Watkins' Web-based Number Theory and Physics Archive *and its speculative twin* Inexplicable Secrets of Creation[1] *– hosted by the mathematics department of Exeter University in the UK where Watkins is an honorary research fellow – have grown into a unique resource. The archive brings together work from the plurality of disciplines contributing to an as yet unnamed field of research concerned with the startling connections between number theory – particularly the Riemann Hypothesis on the distribution of the prime numbers – and the physical sciences. Watkins talks to* **COLLAPSE** *about his rôle in, and motivations for, catalysing and disseminating the field, about the latest developments in the search for the hypothetical 'Riemann dynamics', about the nature of discovery in mathematics and its academic and cultural status.*

---

[1] *At* http://www.maths.ex.ac.uk/~mwatkins/. Dr. Watkins has kindly assembled a 'primer' for the mathematical concepts discussed in this interview: at http://www.maths.ex.ac.uk/~mwatkins/zeta/collapseglossary.htm

COLLAPSE I, ed. R. Mackay (Oxford: Urbanomic, September 2007)
ISBN 978-0-9553087-0-4
http://www.urbanomic.com

Collapse: The primes have perennially been hailed as ‘mysterious’. In modern mathematics this mystery has condensed around the problem which Riemann's Hypothesis concerns. We can find primes as we count along the number line, but we have no way of predicting in general where and how densely they will occur. A lack of determinable global order, then.

Matthew Watkins: But first there’s a major question concerning what is meant by ‘order’. I’m often asked, is there a pattern in the primes, is there an order, but what does that mean? If you try to reformulate these questions very precisely, you’re forced to consider what it would it mean for there to be order, or a pattern. I mean, there are patterns like wallpaper patterns, where you have a block of something repeating. Well, almost by definition the primes can’t do that. But what sort of pattern could there be, what sort of order could there be? The idea that there might be a pattern, the importance of there being a pattern in the primes – these aren’t things you can rigorously pin down.

C: Couldn’t you use an information-theoretical definition of pattern?

MW: You could come up with a definition, one of an endless number of possible definitions, from information theory or some related discipline, of what a pattern is, and then apply it. But I think there's still the basic fact that when people who aren't familiar with any of those definitions are asking 'is there a pattern?' they don't mean anything that such a definition could capture, they mean something else – they don't really know quite what, but it seems important to them that there should be; whether or not there is a pattern in the primes they see as an important question. And it struck me when I was thinking about this that it's more *feeling-based*, it's not a rational question they're posing. You can try to construct rational questions around it. People have, and such questions have given rise to a large part of that body of work we call number theory.

C: But initially it's more like the expression of an instinct for pattern recognition?

MW: Perhaps. As Jung said – almost as the culmination of his work on archetypes – the set of positive integers, taken as a whole, corresponds to the *archetype of order*. So, in a sense, all notions of order, of something coming before something else, of things being in a sequence, all of that ultimately can be linked back to our instinctive grasping of there being a number system underlying our experience. Now that number system turns out to have embedded within it an enigma, a problem bordering on the paradoxical: is there order in the way this thing's put together or not? We feel there should be, but we aren't entirely sure how to ask the question – basically, we don't really know. So we start by asking whether there's order in the number system, and the unintended result of our probing into this matter is that what we ultimately mean by order *in any sense* gets indirectly thrown into question.

People also frequently ask about the existence of a *formula* – is there a formula for the prime numbers? Well, again, that's difficult because, yes there is, there's the Riemann-von Mangoldt explicit formula, which effectively generates exactly the distribution of prime numbers as 'output' – but you need the complete set of *Riemann zeros* as input. This is an infinite set, and to produce it you effectively need the complete set of prime numbers, so there's a circularity. So it's a formula, but not the kind of formula which people who ask this question have in mind. There are also algorithms – rigorous procedures – which can systematically generate the primes. One could arguably call these 'formulas', but they're basically methods of computation, and the computations quickly become intractably huge…so we're not talking about anything that can systematically spit out primes one after another in the sense that people might have in mind when they ask about the existence of a formula.

C: As the years have gone on, mathematicians' ingenuity and the employment of new technologies have seen an acceleration in the conquest of the critical line of Riemann zeta zeros. But does the fact we've got, say, one billion of the zeros make it any less mysterious than when we had a hundred? Does the apparent success of the Riemann Hypothesis (RH) militate against the conception of the primes as mysterious?

MW: First of all, you can't really talk about RH being 'successful', it's still a hypothesis. RH doesn't predict the primes as such, but the theory of Riemann's zeta function, from which it emerges, allows us to understand the distribution of primes much more deeply. At the heart of this theory is the peculiar sequence of 'zeros' now known as 'Riemann zeros', 'Riemann zeta zeros' or sometimes just 'zeta zeros' – these are what RH directly concerns.

What's happened really is that RH has displaced the mystery. The primes are no longer mysterious, you could argue – we now know that they are exactly governed. Initially, it was found that they're governed by a logarithmic distribution, a sort of gradual thinning out, in an almost statistical sense – that provides reliable but approximate information about the primes. Riemann later found that the logarithmic distribution is 'modulated' by an infinite set of waves, where each wavelength corresponds to one of the Riemann zeros. We're in the realm of proven mathematical results here, and these *precisely* pin down the primes, so in that sense, all mystery is gone; but in actuality the mystery has been pushed back, or displaced. The mystery now is, *where the hell did these Riemann zeros come from*? We can calculate hundreds of billions of them, we've got a vast, intricate body of precise mathematical results concerning them which ultimately brings us to a big, important, question about whether they'll all lie on the 'critical line' – that question is RH. But ultimately, what *are* they?

Since the seventies, this idea that they might be *vibrations of something* has taken root and has now been more-or-less universally accepted, on the basis of a lot of computational evidence together with a mysterious, suggestive mathematical 'coincidence' involving something called the Selberg Trace Formula – and that ties in with certain unexpected connections with physics.

So if we've got vibrations of a mysterious 'something' underlying the number system, in a sense the primes are no longer the mystery, the primes have been taken care of, the mystery has been displaced. The primes are our obvious way into the mystery, but ultimately it's a mystery about the system of positive integers, about 'order', and arguably even about *time*.

C: To return to the question of order, are the zeros any more ordered than the primes?

MW: The set of primes and the set of Riemann zeros are in some sense 'dual' structures. There's a variant of what's called a 'Fourier duality' between them. To put it simply, you can use the zeros to generate the set of primes: if you have just the zeros and the explicit formula, you can effectively ‘put the zeros in and get the primes out’. And it also works in the opposite direction. So the two generate each other. In a sense the primes are more well-behaved in that they’re all integers, they all fall on this nice ‘grid’ of positive integers. The primes can be explained to a schoolchild, a five-year-old is capable of understanding the idea of prime numbers. They are there among the familiar positive integers, the usual counting numbers, and counting is a ubiquitous part of our everyday experience.

They’re dual, so in some sense the two could be seen as equally important, two sides of the same coin. However, the Riemann zeros are very different – they’re not integers, they’re what we call ‘transcendental’, irrational numbers; you need a degree in mathematics before you can even begin to understand the definition of them, and relative to the total population, only the tiniest handful of people have any real understanding of what is currently known about them. And they appear to have absolutely nothing to do with ordinary everyday experience.

C: We could say that the zeros are not a solution to the problem, but the problem itself, expressed in a domain that’s more difficult for us to access; the exact nature of this domain then becomes the real focus of interest.

MW: Yes, the zeros are the problem, and thus the problem's been displaced to somewhere we're much less familiar with. Counting, you know...Ancient Greeks and earlier people could count pebbles out on the ground, subdivide them into piles and contemplate different types of numbers – 'perfect numbers', 'triangular numbers', prime numbers – and they were able to develop a certain amount of theory. But that's just one side of the coin. On the other side, there was no way they could have contemplated the Riemann zeros: (a) you need a theory of 'functions of a complex variable', and (b) in order to calculate more than the first handful of them you need a pretty powerful computer.

It reminds me of the central image in the film *2001*: It's as if we've dug this monolithic thing up, it's been there for aeons, as a structure it's overwhelmingly impressive, and everyone concerned is flabbergasted, asking themselves how did *that* get there, you know: it comes from *somewhere* else, somewhere beyond, and it induces a sense of almost religious awe.

One suspects that if a mathematical structure underlying or 'explaining' the Riemann zeros were to emerge – that is, if in fifty or a hundred years someone comes up with something new which 'explains' the zeros in the way the zeros 'explain' the primes – then that new structure is just going to open up another even deeper mystery. Paul Erdös, who published more mathematics papers than anyone else ever, and who was primarily a number theorist, said that it's going to be at least a million years before we understand the primes, and even then we won't really understand them.

C: Is it a properly transcendental problem, relating to the limits of our thought: the more that we think, the further the problem moves away from us?

MW: Well, again, we don't know that yet: it may be, but then who knows – maybe it'll all neatly tie up somehow. But it *feels* to me that the problem has a quest-like quality. The fact that the metaphorical image of the Holy Grail has been invoked a few times in the literature, as well as a lot of language poetically invoking the feminine and generally suggesting an 'otherness', suggests that I'm not the only one thinking like this. I've had an interesting dialogue with some Jungians about this aspect of RH.

The problem of the primes isn't just different from other mathematical problems, it *precedes* them. All other mathematical problems rely on the fact that there are positive integers. Without the set of positive integers, those other mathematical problems couldn't exist. So the problem of the primes is *the* problem in a sense, it's beyond the most basic, it's there before all the others are there. As soon as you've got counting, as soon as you've got any notion of repetition, then the problem of the primes is there waiting to be discovered.

If we don't understand the prime numbers, we don't understand the positive integers. And if we don't understand the positive integers, then I don't know if we understand anything at all, because all science is entirely built on measurement, and you can't measure anything until you can count. All our rational scientific thought relies on these very basic ideas of order and counting.

One of the most important quotations that I've reproduced on my website is this, from Gerald Tenenbaum (Institut Élie Cartan):

> As archetypes of our representation of the world, numbers form, in the strongest sense, part of ourselves, to such an extent that it can legitimately be asked whether the subject of study of arithmetic is not the human mind itself. From this a strange fascination arises: how can it be that these numbers, which lie so deeply within ourselves, also give rise to such formidable enigmas? Among all these mysteries, that of the prime numbers is undoubtedly the most ancient and most resistant.[2]

So, in probing the mystery of the prime numbers we're effectively on a sort of journey to the centre of the mind, or of the collective human psyche, and ultimately to the point where that interfaces with the physical world which it finds itself inhabiting. That quote perhaps best conveys some feeling as to why I'm so gripped by this stuff.

C: The story of the modern theory of primes begins

---

2. G. Tenenbaum and M. Mendès France, *The Prime Numbers and Their Distribution* (AMS, 2000) p.1

with Gauss's initial success in predicting approximately the distribution of primes. How do we get from there to the pioneering interdisciplinary work that your web-archive charts?

MW: Gauss – although he didn't publish, he supposedly got there first – Gauss and Legendre noticed that there was at least a 'statistical' thinning out of the primes that you could quantify. Riemann later uncovered the zeros of his zeta function – the Riemann zeros – and so was able to pin it down much more rigorously. But there's a fifty-year gap where...actually, I don't know what mathematicians felt during that time. Practically, they were trying to refine the approximations; Chebyshev and others improved the approximation of how many primes you'll find in any given chunk of the number line. But whether there was an expectation that eventually someone would find a way to make this exact, or whether there was a general feeling that 'this is the best we'll ever do', I don't know, and I can't recall seeing anything in the literature of that period where feelings about this matter were expressed. Once Riemann's work came along then no-one was really interested in what people *used* to think. The history of mathematical ignorance isn't as well documented as the history of mathematical discovery.

There are some parallels with the situation we're in now, where there's a mystery about this proposed 'Riemann dynamics', this hypothetical dynamical system underlying the Riemann zeros.

C: The complex plane is the most important mathematical support of RH itself. And here already a transformation takes place – de Sautoy[3] talks about it as a sort of magic mirror we step through – which seems to unfold things we thought we knew, in a completely different space – as it turns out, very fruitfully for mathematics and the physical sciences alike.

There's obviously something very powerful about the complex plane itself which, at the very least, corresponds in some way to physical reality, and so the fact that it was also the complex plane which facilitated Riemann's insight into the prime distribution is itself suggestive.

MW: The complex plane appears to have a life of its own. Complex numbers are absolutely necessary to describe quantum-mechanical phenomena. Electricians use the complex unit *i* just to work with AC electricity, so something as 'nuts-and-bolts' as the National Electricity Grid depends on the complex plane. And yet it is this supremely mysterious thing. I mean, all those fractals that started to circulate in the 1980's – a lot of people don't realise what they're looking at, but those are things that naturally inhabit the complex plane. Without the complex plane you wouldn't be able to see such objects, that's their natural domain. And then the Riemann zeta function, with all its strange properties; Riemann's big step was to take a function which Euler had looked at and ask, what would that do if we extended it into the complex plane? And what it was found to do then spawned the great mystery of the Riemann zeros.

---

[3] De Sautoy, M. *The Music of the Primes*. London: HarperCollins, 2004

Another strange thing worth mentioning: One tends to think of temperature as existing on a linear scale, a one-dimensional scale. But in statistical mechanics, by constructing a function of temperature, the 'partition function', and extending it out to the complex plane, you find that it has a set of 'singularities', off the familiar real number line, in this other two-dimensional region that doesn't seem to have anything to do with temperature or any other aspect of practical measurable physical reality. Yet these singularities correspond to *phase transitions* of the system. Without the complex plane you'd never have known they were there. The same thing happens with the zeta function, it's got a set of singular points in the complex plane, the Riemann zeros off the real line. From the behaviour of the zeta function *on* the real line, you would never have guessed they were there.

Various people have put forward models of two-dimensional time – imaginary time certainly gets used, complex time. Such models can be used in attempts to explain otherwise inexplicable phenomena, but none of this can be applied to our normal experience of reality, you can't really do anything with it. I would say that the complex plane is still deeply mysterious. It's 'behind the scenes' of reality as we experience it.

C: And historically, complex numbers had been discovered long before there was any sense of their ultimate utility. Only later did it became evident that something which seemed to have been a mathematical fiction, was hugely important to work in these fields.

MW: Absolutely, the word imaginary, you know – you've got the 'real' numbers and the 'imaginary' numbers – it's a very unfortunate name, but it's simply because of the history of the thing. For quite a while, no-one thought these things had any 'reality' to them, primarily because they didn't correspond to anything experiential in the way 'real' numbers were seen to.

C: It's difficult to ignore this experimental evidence that complex numbers relate to something in reality: we have to take account of these things which just impress themselves upon us. The traits of the complex plane are obviously real, but they don't correspond to any actual object, any actual thing we can get hold of. They're distributed through reality itself.

MW: Yes, the system of complex numbers is there, I don't know 'where' it is, but it's not just something we *invented*. And, interestingly, it's most directly evident at the subatomic level. As I said, the theory of AC electricity relies on it, but then ultimately that's a quantum-mechanical phenomenon, scaled up to the level where we can, say, run a toaster on it. Functions of a complex variable get used in statistical mechanics, aerodynamics, *etc.*, but those are fairly indirect manifestations of something very deep, I feel. The fact that the complex plane relates so closely to quantum mechanics means that in macroscopic reality, it permeates everything, as you say, and yet nobody had a clue it was there until relatively recently. Even after it had been mathematically brought into consciousness it was still seen as just a fiction.

As for the primes, you can't understand the distribution of primes until you've grasped the Riemann zeros. And the Riemann zeros live on the complex plane, inarguably. The 'nontrivial' zeros, the ones RH concerns, inhabit a narrow vertical strip in the complex plane. The RH simply says that they all – the entire infinite set of Riemann zeros – lie on the 'critical line' which runs up the middle of this 'critical strip'.

Now, to prove RH would be an exact mathematical task, so RH gets a lot of press – there's the whole fame-and-fortune thing, literally a million-dollar prize, this idea of something like winning the ultimate intellectual gold medal, you know – but you've either done it or you haven't, it's very clear-cut. But I'm more interested in the less clear-cut questions – what *are* the Riemann zeros, from where do they originate?

To answer this we may need something else as new

---

4. See http://www.claymath.org/millenium/

and unexpected as the complex plane was when it was first introduced, something we haven't thought of yet, a new mathematical 'environment' in which these things will become perfectly clear. But that may well lead to another body of questions which are even more baffling.

But "from where do the zeros originate" – what does that mean? They're seemingly vibrations of something, but what? What is that thing going to be – is it going to be a mathematical model of a dynamic system that people may or may not be able to physically manifest? If it is possible to physically manifest it and someone does...what then are we confronted with?

One gets a very strong feeling that until we understand the what the zeros 'are', we won't be in a position to prove RH. These two issues are tied together. But the former isn't yet a precise question, whereas 'is the RH true' *is*.

C: It is said that in mathematics a question isn't even a question if you can't formulate it precisely: mathematics is the art of formalising problems, so if you can't do that then in a sense it falls outside of mathematics.

MW: Yes, and so something with this kind of quasi-mathematical character is generally regarded with a certain suspicion; it's neither one thing nor the other.

C: A mystery rather than a problem, then.

MW: Yes, and I suppose I tend to be attracted to the mysteries.

C: Practically speaking, how does the hypothetical positing of a Riemann dynamics change the nature of the search for a proof of RH?

MW: It brings other people in, it brings the physicists in. Before, you had analytic number theorists hammering away at this problem. And now probability theorists, geometers and physicists are all contenders, and they all have pieces of the puzzle. It's broadened the scene, if you like, of people concerned with the problem. But it also has given a deeper sense of what's at stake; again, if there is a dynamic system underlying the Riemann zeta function, well then it underlies the number system; if it underlies the number system then it underlies everything, or at least everything that rational scientific thought concerns itself with. And so, again, we're force to ask what is it, where does it 'live', what does it 'do'? And perhaps the most important question is, *what is the time parameter*? Because a dynamical system always has a time parameter according to which it 'evolves' – so what kind of time are we talking about in this case? So it basically opens a whole new can of philosophical worms. It makes me think of what Hilbert said, when he was asked about RH, he said that it isn't just the most important problem in mathematics, it's the most important problem. And I think a lot of people might just think, yes, that's because he was a mathematician, he was biased...but I think he knew what he was talking about. He and Pólya first proposed that there might be a 'Riemann operator', that the zeros might be a spectrum of something. They didn't suggest a dynamical system as such, but they could be said to have laid the groundwork for that. So I think Hilbert may have sensed something very big going on there, which he was trying to express in that pronouncement.

C: The first steps towards elaborating the nature of the Riemann dynamics comes with Julia's interpretation of the zeta function as a thermodynamic partition function. What is a partition function, and in what sense can one speak of the primes as a numerical gas – Julia's 'free Riemann gas'? Is it simply a useful metaphor taken from thermodynamics, or is there a more substantial link?

MW: Well, firstly, Julia's work doesn't directly address the issue of the Riemann dynamics, although there may well be a deep connection there.

Your last question is difficult to answer, but it would be hard to deny that there's a sort of a metaphor here, in that there's a strong resemblance between certain aspects of the zeta function and the theory of thermodynamic partition functions. But it goes deeper than a superficial resemblance. There are enough corresponding elements, that Julia included what he called a 'dictionary' in the paper he first published about this.[4] It consists of two columns, with number theoretical structures on one side and corresponding thermodynamic structures on the other. And the correspondences are such that, if you're sufficiently familiar with number theory and statistical mechanics, you can't deny there's something...there's a very strong link there. So you could call this a metaphor, but I would maintain that it's more than just a metaphor in the familiar sense, *i.e.* a useful way of explaining what something is by means of something else which isn't directly related to it.

Now what is a partition function, in statistical physics, or statistical mechanics? Well, in classical mechanics, a billiard table is often used as an example: you've got a finite number of billiard balls bouncing off each other, bouncing off the sides, they're colliding, energy is being transferred between them, there are various angles, positions and momenta involved. And the idea is that you've got a sufficiently simple system that you can keep track of each individual object and what it's doing. But a problem arises when you've got something like a box of gas: that's effectively like a giant three-dimensional billiard table, but there are too many components to keep track of what each one is doing. You're not actually going to be able to do anything in that way, so you're going to have to study it in the sort of way sociologists study society – they can't possibly consider all the specifics of each individual person, so they must look at overall statistical trends in the population.

---

[4] Julia, B.L. 'Statistical theory of numbers', in M. Waldschmidt, et. al. (eds.) *Number Theory and Physics*. Springer Proceedings in Physics 47 (Springer, 1989)

Suppose you had a quantity of gas particles in this room, and they were all roaming freely. It would be very surprising to find them all clustered up in one corner. One expects a more uniform spread. But, *there's no real reason they can't do that.* It's like if I toss a coin fifty times, I'd be very surprised if I got fifty heads or fifty tails, but there's no reason why that can't happen. That would be no more unreasonable than any other outcome of fifty coin-tosses, it's just that it's extremely *improbable* because, unlike any other outcome, *there's only one way of arriving at it.* Similarly, there are proportionally few possible configurations of those gas particles where they're all squashed in one corner, compared to the vast proportion of configurations where they're more-or-less uniformly distributed.

Now suppose you have a box of gas, and the gas consists of particles which can jump between different energy levels in an effectively random way. This time you're concerned, rather than with the spatial distribution, with the *total energy* of the system – that's simply what you get when you add together all the individual particle energies. You can ask about the probability of the system having a particular total energy, and it turns out to be rather like the situation with the spatial distribution. That is, the system tends towards a mid-range total energy on the whole, while the highest and lowest ranges of *possible* total energy are much more improbable – because their occurrence requires something akin to a huge number of coin-tosses producing almost all heads or almost all tails.

So what you're looking at with thermodynamics is the probability that you'll find a box of gas or some similarly complex system in one state or another. And the partition function takes a unit of probability and 'partitions' or subdivides it, so that you end up with a curve describing in precise terms the relative probability of finding the total energy of the system at any particular level. So the partition function will basically return probabilities that a system is in one of any number of possible states. The partition functions Julia refers to are functions of temperature – as the temperature of the system varies, the probabilities also vary, and the partition function is able to provide a precise probabilistic distribution of possible total energies at any given temperature.

Now partition functions, it turns out, are the key to understanding statistical mechanical systems; they 'encapsulate' such systems. The partition function in this context is a function of temperature, and temperature would naturally be seen as a variable which varied on the real line – on the *positive* real line, if you're working with absolute temperature. Well, nineteenth century mathematics suddenly allowed the possibility of extending such a variable to the complex plane, regardless of what a complex-valued temperature might actually refer to. You take your partition function which is supposed to be returning probabilities of a system being in some energy state or other based on a real-valued temperature variable, extend it to the complex plane, and you find there are singularities hidden out there which tell you about the possible existence of phase transitions in your system. These are very important for understanding the system, but, as I said earlier, you wouldn't see them if you didn't have access to the complex plane.

Now Julia wasn't the first – George Mackey got there first, although it wasn't widely noticed. Julia discovered it independently and then Donald Spector, a couple of years later – they all noticed that if you treat the primes as your basic particles, and each prime *p* is thought of as having as its 'energy' the natural logarithm of *p* – that logarithm turns out to be very important, logarithms show up everywhere in analytic number theory – then the Riemann zeta function very naturally falls into the rôle of being the partition function of an abstract numerical 'gas' which is made of this set of particles – what Julia calls the 'free Riemann gas'. Imagine a fluctuating integer, where prime factors are coming and going all the time, joining and leaving, so the energy of that integer is going up and down, the more prime factors there are the higher the energy, and the less prime factors the lower the energy. The zeta function naturally becomes the partition function of such a system. The 'pole' of the zeta function – this unique singularity of the zeta function at the point 1 in the complex plane where the zeta function isn't defined, where it effectively becomes infinite – corresponds very naturally to something in thermodynamics called a *Hagedorn catastrophe*, a phenomenon involving the energy levels crowding together so the system hits a critical state and shifts into an altogether different mode. So the pole of the zeta function is associated with this 'catastrophe', and based on what I was just saying, the Riemann zeros also become linked to phase transitions, in a way that no-one entirely understands. And there's more...those are just the basic points, there are further subtleties which suggest that, in some sense, thinking of the zeta function as a partition function goes beyond mere metaphor. It's a metaphor, but it's a metaphor that goes deep enough to suggest to me that *the number system has some sort of quasi-physical quality*.

C: How are we to interpret this? There's a perplexing quality to these propositions, one is never sure whether what's being revealed is a progression, or simply a restatement of the same problem in different terms.

MW: Possibly, but you see, the mathematics that's come out of studying things like boxes of gas, *that that should be applicable at all* to studying something as fundamental as the positive integers, to me comes across as sort of *uncanny*. I think that's a good word to capture how a lot of people have reacted to these discoveries. It's hard to see how it's simply a reformulation of the problem.

You'd never have got there if you hadn't studied the boxes of gas in the first place. When you ask how we can best interpret this, the only answer I can come up with is I honestly don't know. To me it points to something fascinating which we haven't yet entirely understood or taken into account.

Now, interestingly, Alain Connes' (College de France, IHES, Vanderbilt) model involving what's called a *C*-dynamical system* – his attempt to try and describe the Riemann dynamics, which hasn't yet fully succeeded, although it's certainly opened up some new vistas – was inspired by Julia's paper, but Connes uses the partition function in a somewhat different sense. The partition functions I've been describing, the ones associated with boxes of gas, *etc.*, could be called 'classical partition functions' as they belong to 'classical statistical mechanics'. But there are also partition functions used in *quantum* statistical mechanics, which take some of the same concepts down to the quantum level.

Connes takes certain elements of quantum statistical mechanics and applies them to the zeta function, treating it as a partition function, and this reveals certain things which again push the metaphor, in my mind, so far that it can't be regarded as *just* a metaphor.

C: So there is a direct link between the quantum-mechanical interpretation and the thermodynamic?

MW: I think there must be, although it's not yet entirely clear what it would be. Of the two most extensive pages in my web-archive, one deals with the spectral interpretation – Hilbert and Pólya's suggestion that the Riemann zeros might be vibrational frequencies of something and Michael Berry's (Bristol University) physics-inspired work concerning what that 'something' might be. Berry and his colleague Jon Keating have outlined a whole set of dynamical properties characterising this hypothetical Riemann dynamics. And the other page deals with the thermodynamic or statistical mechanics side of things – you've got Julia, Spector, Mackey, who all put forward the idea that the zeta function is a partition function, which would suggest that the zeros are in fact phase transitions of something. So these two currents of research are seemingly different approaches, not obviously compatible. Alain Connes has begun to bridge the gap, though. He has taken Julia's suggestion about zeta as a partition function, shifted it into the realm of quantum statistical mechanics, and then brought in *p*-adic and adelic number systems, and a lot of other very deep mathematics including something called noncommutative geometry, which is about as difficult as current mathematics gets. He's managed to describe a dynamical system, or at least sketch out the beginnings of one, which produces the Riemann zeros as vibrational frequencies, but where the zeta function is also playing the rôle of a partition function, so there is a link there.

C: Connes' *adele* is an infinite-dimensional space in which each dimension is folded, so to speak, with the frequency of each prime.

MW: Yes, that's almost it. An adele is a generalised kind of number which contains an infinite number of co-ordinates, one associated with each prime number, effectively, and then an extra one, which corresponds to the continuum of real numbers.

The adelic number system embraces all of the different *p*-adic number systems – 2-adic, 3-adic, 5-adic, 7-adic, etc. *p*-adics and adeles constitute yet another aspect of number theory finding its way into physics, thereby suggesting that things aren't the way we thought they were.

The Archimedean principle, the basic principle of all measurement, is based on rational numbers, on ratios. If you have a line segment and a longer line segment, by taking the shorter line segment and joining it end to end a finite number of times, you will always be able to exceed the longer line segment. That seems obvious – it's the basis on which I can take a ruler and measure this room. If I kept joining it end to end and I never got to the end of the room, then measurement wouldn't work very well! So, the universe at the macroscopic scale is Archimedean: the Archimedean principle applies. And the number system we generally use, the continuum of real numbers, is an Archimedean system.

Now, the real number continuum is based on a particular arbitrary choice of how we 'close' the system of rational numbers. The rational numbers are fairly simple, well-determined, or given, if you like – canonical. You've got your integers, and then you start taking ordinary fractions and that fills in the gaps – it doesn't fill in *all* the gaps, but it densely fills in the number line. The 'holes' that remain are the irrational numbers, which can't be expressed as ratios of integers, $\sqrt{2}$ being the one that, it's widely believed, was first discovered, and π being undoubtedly the most famous. But there's not just a handful of exceptions, these irrational numbers are in some sense *more common* than the rational numbers.

The question is, given the system of rational numbers, how do you fill in the holes, how do you seal the whole thing up? Well, the method we've ended up adopting produces the system of real numbers, which is a system in which the Archimedean principle applies. And that's based on defining the holes, the irrational numbers, as the 'limits' of sequences of rational numbers. But to define the limits, you have to have a sense of distance; put simply, a sequence *converges* when its elements get closer and closer to something, and the notion of 'closer' requires some sense of distance. The sense of distance we use to define the real numbers is the obvious one: the distance between any two rational numbers on the real number line is what you get when you subtract the smaller from the larger. But that's an arbitrary way of defining distance. It turns out that, within the logical constraints which apply, there are an infinite number of other meaningful, consistent ways you can define what distance is, and each leads to a different notion of 'closure' and hence to a different number system. So you're still starting with the rationals, but the way you 'fill in the holes' is completely different, and you end up with a different kind of mathematics. Now this was discovered by Hensel in the late 1890's, and very quickly the possible ways of closing the rationals were classified. It turns out that there are infinitely many of them, and that they correspond to prime numbers: there's the 2-adic system, the 3-adic system, the 5-adic system, the 7-adic system, all the way up, and then finally there's the ∞-adic system, which corresponds to the usual system of real numbers, and which suggests the existence of what's called the 'prime at infinity', a deeply mysterious thing, which an Israeli mathematician called Shai Haran has written a whole book about[5].

But the point is, in a 2-adic, 3-adic or 5-adic number system, the distance between two rational numbers has nothing to do with the traditional distance between two points on a ruler anymore, rather it's about arithmetic relationships involving divisibility of numerators and denominators by the prime p which characterises the p-adic system in question. So things that would look very close together on a ruler could be huge distances apart, and vice versa, things that are vast distances apart in a normal Euclidean sense could be very close together in a *p*-adic sense.

---

[5] M.J. Shai Haran *The Mysteries of the Real Prime*. London Mathematical Society Monographs, Oxford: OUP, 2001.

C: And the adelic system is built up of all these?

MW: An adele is a generalised number which has an infinite number of co-ordinates. One's a 2-adic number, one's a 3-adic number, one's a 5-adic number: one for each prime. They're usually written as:

(2-adic number, 3-adic number, 5-adic number...; real number)

so you get one of each. When, at the end of the nineteenth century, these *p*-adic number systems were discovered, it was realised that we've been doing all our physics on the basis that time and space are like the real number continuum. That's the assumption; all the Einsteinian, Riemannian, Minkowskian manifolds, space-time manifolds, were based on real numbers extending in different dimensions. But why should we assume the universe is 'real', in that sense? You could formulate a 17-adic manifold and do space-time physics in it, or a 37-adic manifold; but then, why pick one prime rather than another? Hence the idea arose, why not chuck them all in, create a system which involves all of them at once – this is the adelic approach, described in very crude terms. Hence *p*-adic and adelic physics – there are people developing models of *p*-adic physics where the *p* is just left as an arbitrary *p*, where it would work for any prime, basically re-building physics according to these new number systems. So you've got *p*-adic models of time, *p*-adic models of probability. A lot of it really turns your ideas of the world on their head.

Now Connes has come up with a dynamical system on a space of adeles, which generates the spectrum of Riemann zeros. The problem is that the system he's starting with has already got the prime numbers built in to it, so some people would say, well, he's really only reformulated the problem. But I suspect there's a lot more to it than that. It's not quite the dynamical system that is being sought in connection with RH, but it is widely seen as a valuable step in the right direction.

Even more interesting than Connes' work, from my point-of-view, is that of the lesser-known Michel Lapidus (University of California-Riverside), another Frenchman with a staggeringly broad view of mathematics and physics. I recently had the privilege of proofreading his latest book – I hope it will come out this year, it's been a long time in the pipeline. It's called *In Search of the Riemann Zeros* and it brings all of these ideas together. And he's taken Connes' idea even further. He's got a set of ideas involving quantum statistical mechanics, *p*-adics and adeles, dynamical systems, vibrational frequencies, partition functions, it's all in there, but also fractals, string theory...

C: The adele already intuitively brings to mind string theory, because of the way everything seems to be bound up with the nature of these peculiarly convoluted spaces.

MW: There's been a lot of work done on p-adic and adelic string theory, but that's not quite what you mean. Lapidus has actually come up with a fascinating connection. He was working on something he called 'fractal strings', but these didn't have anything to do with the 'string theory' physicists study, it was just the name that he had given to these particular mathematical objects. And then he generalised them to something called 'fractal membranes'. But since he came up with that, oddly enough, he's found that aspects of string theory relate directly and unexpectedly to the mathematics. His model involves a dynamical system, a *noncommutative flow of fractal membranes in a moduli space*...

C: Which sounds wonderful!

MW: Yes, at a very naïve level, I just enjoy all the extraordinary language. But, more seriously, I have a certain emotional investment in Lapidus actually being onto something, because if he's correct, it turns out that his 'flow', this very strange, highly counterintuitive, noncommutative geometrical 'flow' projects down into a simpler realm, into the number system, as a flow of 'generalised prime numbers' on a line. This is very close to some strange speculative ideas I made public back in

1999[6]. Lapidus contacted me a few years ago to say this, as it had come to his attention when I first put it up on the Web. Now, it's not that I influenced him, it's almost as if I caught a glimpse of some future mathematics which will follow from his current work. I don't know how I can explain what happened… it's as if I caught a glimpse of something which was coming, but I didn't have the language to describe it accurately, so I just described it as well as I could in this rather naïve way. And so in a way I now feel somewhat vindicated concerning my slightly crackpot idea, because of Lapidus' work.

*

In some ways, I think all this intellectualising and mathematics isn't really that good for me, and isn't really what I 'should' be doing. But part of me can't entirely detach myself from it. The speculation I just mentioned, which now appears to be at least partly vindicated, gripped me in a profound way. This event had a precedent a few years earlier when I became *convinced* there was some connection between the Gaussian probability distribution and the prime numbers: that was driven by a sort of compulsion that was, looking back, was quite...not psychotic – it didn't lead to any sort of negative behaviour – but it did rather take over my psyche.

I was one of those kids who, it was obvious fairly early on, could excel at mathematics, and being a fairly scrawny, unattractive young person, one latches on to anything one is good at – it provides a sense of importance. It was as simple as that, it wasn't any sort of noble motive for seeking the truth or anything. I was living in the States as a teenager, starting to get interested in things like radical art movements and philosophy. If circumstances had been different I'd have probably studied something else, but I wanted to get out of the States, that was quite a big thing for me then, so to get into a British university my best bet was to apply to do a maths degree, which I did. And then I sailed through that, and got offered a place on a PhD programme, which seemed like a great idea – effectively being paid to explore ideas which I found quite interesting and which I seemed to have an aptitude for exploring. So that was all fairly accidental, and there was no real motive behind it, if you like. It was just the way my life unfolded. But by the time I was doing the PhD I was starting to engage with a lot of other non-mathematical ideas and people, and there was a real sense that, hang on, where is this going, is this really what I want to be doing? At that point I was more interested in 'seeking the truth' – it sounds a bit grandiose, but I wasn't interested in a stable career, and the idea of deriving some sort of self-esteem from being an accomplished mathematician, that no longer seemed to be of any importance. So I started thinking, if I'm seeking the truth, is the truth to be found here, is this really what I should be doing? And then the disillusionment set in. After a year of being on a Royal

---

Society European fellowship, there was a distinct sense that modern mathematics was becoming irreparably fragmented, and I felt like I was being made very comfortable in an ivory tower, in a vast field of other ivory towers, between which there was relatively little communication. And then there were all sorts of personal factors, just the way my life was going, people I knew, a sense of imminent global catastrophe...

This was 1995, so perhaps there was a touch of millenarian hysteria involved! There was a sense that, as a mathematician, I was part of the problem rather than part of the solution. A lot of my friends were involved in ecological activism and things like that, and I started to formulate a worldview wherein science had become the new, unacknowledged, religion of industrialised society, and mathematics was the inner priesthood of science. To put it in very simple terms, Western culture runs on science, and science runs on maths. So I saw myself as being trained up for this priesthood which was unconsciously steering the world to complete destruction and meaninglessness. And so there was a sense of guilt, almost, that I was involved in this. So I just broke out and floated around doing all sorts of interesting things for a few years, had a great time – I don’t regret that at all. I never imagined that I’d get involved in mathematics again.

But then certain ideas about prime numbers started to percolate in my mind. I’d never really looked at number theory in any detail, had just a very basic number theory course as an undergraduate. But shortly after I 'dropped out', I started thinking about prime numbers and the fact that they have a sort of 'random' quality…and at the same time thinking about the Gaussian distribution, the bell curve, and the ubiquity of that, the fact that almost anything that you can name, count, measure, and gather data on tends to scatter along this particular ideal exponential curve. I remember posting a question on an Internet newsgroup back in 1995, trying to get somebody to explain to me why this thing shows up everywhere: not just in the biological realm, but in much more convoluted 'cultural' realms – I expect that you could count the number of appearances of a letter of the alphabet on the front page of a newspaper over so many years or months, and you'd find the same thing. And the purely mathematical explanations put forward made sense to some extent, but I still felt there was some huge mystery lurking behind the Gaussian distribution, the fact that it shows up everywhere. I scribbled all sorts of half-baked ideas down, some of which seem ridiculous now, some still of great interest. But I became convinced – and I still don't know where this came from – I became *utterly* convinced that the distribution of prime numbers in some sense was very deeply linked to this, to the ubiquity of the Gaussian distribution, that they were two sides of something.

And what's strange is that almost seven years later, I discovered there was something called the *Erdös-Kac theorem*, which was proved in 1940, and which I'd never even heard mentioned before. This was the beginning of *probabilistic number theory*, and it basically states that the distribution of prime factors of large integers follows a Gaussian distribution. Obviously, the larger the integer, the more prime factors it is likely to have, but you rescale in a way that takes that into account, so you're dealing purely with the seeming randomness in the fact that some numbers have got lots of prime factors and some numbers have only got one – and you end up with a bell curve. And not just an approximate one, this is what really struck me: if I was to measure the population over time of sparrows in the garden out there, or the way that those sunflower seeds fall on the ground [*pointing to bird-feeder hanging in a tree*], if I had large enough numbers I may well get very nice approximations of the bell curve. A high-resolution computer image might even match the ideal mathematical bell curve in every detail. But they're *always* approximate; in fact all use of statistical inference in science is based on finite amounts of data, which give rise to approximate bell-curves or other distributions. With the Erdös-Kac theorem on the other hand, the *n*, the number of elements in your data set, *actually* tends to infinity. This is what really struck me about all this: *n* can tend to infinity only when you have an infinite amount of whatever it is you're dealing with. And integers are the only thing, effectively, which we have – at least theoretically – access to an infinite amount of.

So, I haven't fully delved into this, but there's a problem with the use of infinity in statistics and probability theory. It's fine in some sort of abstract Platonic sense, but when you start applying it to the world, *there is no infinity*. But it does apply absolutely, precisely – and this is the theorem which Erdös and Kac proved – that as *n* tends to infinity, the distribution of prime factors tends to this distribution. So, in some sense, that's the only 'true' Gaussian distribution there really is, the 'oldest' one, the most primordial. As soon as you've got positive integers, that's hidden there within them. Any other instances of the Gaussian distribution, you know, bird populations or currency fluctuations or anything else like that, not only are these approximate, but they require all sorts of complicated categories and definitions. So, anyway, I still can't quite explain why I was so gripped by this idea of the prime numbers and the Gaussian distribution being linked, but I was, and it's as if I was somehow unconsciously aware of something and couldn't manage to pin it down, you know. I tried endlessly to find some way of relating these things and failed. Had this been 2005 rather than 1995 I probably would have quickly found out about the Erdös-Kac theorem using web-searches.

So as a result of this unresolved compulsion, I had a certain amount of prime number-related activity going on in my mind. Then, in the winter of 1998 I went back to the States to visit my parents who were still out there, and I had a lot of free time. I found a long thin piece of cardboard and drew a number line, circled all the prime numbers, and then started drawing arcs between the prime numbers and their multiples. So every number was connected to all of its prime factors by arcs emanating out from that number to the left. The number fifteen would have two arcs emerging from it, one going to number three, the other to five. And a prime number would have no arcs going to the left, only arcs going to the right. Now obviously you can never draw the complete thing, but I drew enough of it that you could get a sense of there being something, a connectedness, a 'messy' connectedness, like a nervous system, or mycelium, or...I don't know, I can't quite describe it, but I just spent a long time looking at this, I had it up on the bedroom wall. And as a result of internalising that image, I started to think that it was perhaps the gaps *between the primes* that were most important…but I was somehow naïve enough to think that possibly no-one else had thought of that, whereas in fact quite a lot of work has been done on the gaps between the primes and yes, they are important. But I started thinking that maybe the gaps, suitably rescaled, are the things which distribute in a Gaussian way. I tried to run some computer models, to calculate the gaps and analyse their distribution – but not having access to the necessary computational power, that wasn't really going anywhere.

And then this image of the interconnectedness of the primes, the whole number system as a single connected entity, with each prime as a sort of 'nexus', the whole thing exploded in my mind – it was something very sudden, and the initial impression I got was that the primes themselves were imbued with a sort of 'charge'...I think I'd read somewhere that average gaps between consecutive primes are logarithmic, that is the average gap between a prime p and the next prime is log *p*, the natural logarithm of *p*. Obviously the gaps can vary wildly from this average, but the average is a precise mathematical result, becoming increasingly precise as we allow *p* to tend to infinity. I was suddenly gripped by this idea that the primes themselves were imbued with a kind of charge, something like an electrical charge, and that that log *p* was the clue, that was the charge of the prime *p*. At the time I was unaware of Julia's thermodynamic approach which associates with each prime *p* the energy log *p*, and also that certain proposed dynamical schemes involve 'orbits' with period log *p* associated with each prime *p*.

C: So the magnitude of the gap before the prime would be its charge?

MW: Well, for sufficiently large primes *p*, the gap before and the gap after would both be approximately log *p*. And I had the idea that these primes were in some sense repelling each other and that the bigger the prime, the greater the charge and the stronger the repulsion, hence the bigger the gap. This all came tumbling in as a single thought, really – the account I'm giving now is an attempt to reconstruct and coherently describe it. But rapidly following this initial impression was the idea was that, well, if there's that kind of repulsion involved then what I'm looking at is a *frozen image of something which was previously in motion* – this is what I got a very strong inner-visual sense of. I try to describe it to people like this: imagine attaching a wire to a wall and then stretching it away from the wall, effectively off to infinity, and then marking out with tiny white dots equal spaces representing the integers, and then imagine little tiny magnetic beads, mutually repulsive particles, positioned along the wire at positions 2,3,5,7,11, *etc*., that is, at the positions of what we call the prime numbers. Now set up a camera, and then subject the whole area to a huge fluctuating magnetic field, causing the beads to move up and down the wire, driven not just by the field, but by their mutual repulsion. Film that, and then run the film backwards. What you'd see is all these particles moving around on the wire and repelling each other, responding to each other, and then eventually coming to rest at the positions we associate with the primes. That's the image.

Now I was well aware of the obvious question: how do we interpret the time parameter here? This is a huge problem – we're not talking about time in the familiar clock sense, not in the historical sense. I certainly wasn't under any illusion that anything like this had 'happened' at any point in the past. I was suggesting that the system had a 'past', but that it wasn't part of the *historical* past, rather of some other time-like dimension. And rather than thinking, that's ridiculous, I won't think that, I tried to suspend disbelief and see where it would take me. So the basic thought then was, okay, if what we're looking at is a frozen image of something which was previously in motion, the motion must have subsided for some reason – so what we're looking at must be something in a state of equilibrium. So, what kind of equilibrium? Well, I came up with a crude notion of 'arithmetic equilibrium': Why have the magnetic beads come to rest where they are? Well, if we freeze the motion at any moment, so you've got an infinite sequence of tiny beads whose positions don't necessarily correspond to positive integers – they could be any real numbers – and then generate all possible finite multiplicative combinations of those numbers, that would produce something analogous to the positive integers. The positive integers, recall, can be generated as the set of all finite multiplicative combinations of the primes. But these new 'integers' would not be anything like the familiar integers, they'd generally be all over the place. They wouldn't be nicely arranged, equally-spaced. But if the particles ever happened to reach the point where they collectively inhabited the positions associated with what we now call the primes, the 'integers' they'd generate would be equally spaced. So, I thought, it's *equal-spacedness* which is a key to this 'arithmetic equilibrium' which, according to my scheme, has been achieved in the number system.

C: Something like an entropic sequence, heading towards an attractor.

MW: Something like that, I was thinking in terms of all sorts of ideas I had partial understanding of – my understanding of physics is very piecemeal, it was even more so then. So many ideas were feeding in. I started to think, how would it begin? Maybe something like a big bang, where you've got all the particles squeezed together at the wall, at the end of the wire, but with something like an infinite magnetic field produced by the wall, and then you let go, and they all explode outwards. At any moment you could freeze the image and generate all the finite multiplicative combinations, the set of 'integers' that they generate: I called these 'generalised primes' and 'generalised integers'. Well, it turns out that Arne Beurling, a relatively obscure Norwegian mathematician, had come up with this idea of generalised primes and generalised integers many decades previously. To better understand the familiar primes he'd started looking at the question, suppose we 'change' the primes, what can we then say about the associated integers and their asymptotic distribution? Martin Huxley (Cardiff University), who's quite an eminent number theorist, got in touch with me as a result of my original website, to say, oh yes, there is actually a name for those, they're called 'Beurling generalized primes'.

C: The distinction being between the primes as we know them and, as it were, a generalised function of 'priming' by which a number system is generated.

MW: Yes, it's a bit like that, taking the idea of the primes not as indivisible integers, but as a set of generators. But the idea of them flowing or moving, no-one as far as I knew had ever put that idea forward. And so I came up with what I decided was almost a 'creation story', some sort of strange mythological mathematics – the creation story behind the number system. Whether there was this 'big bang' thing at the beginning or not, I wasn't sure...but the idea was that, okay, these generalised primes were somehow set in motion. Remember, there are these generalised prime particles, and then there's a kind of invisible set of generalised integers that they're embedded in, that they're generating, which are also in motion. And, at any moment, the 'heterogeneity' of these generalised integers, their lack of equal-spacedness, is creating some kind of 'tension' which is affecting the particles' charges. The idea of fixed log p charges gave way to the idea of fluctuating charges, governed by the spacing within the generalised integers at any given moment. So you can almost think of the distribution of these generalised integers trying to space itself out by 'influencing' the generalised primes and their charges so that their mutual repulsion eventually leads them to a stable configuration, an attractor point – that would be the arithmetic equilibrium. Having reached that – the familiar configuration of primes – the generalised integers would be nothing but the familiar positive integers 1,2,3,... The perfect equal-spacedness of these would result in all forces on the generalised primes dropping away, and the number system has then 'come into being'.

That was the 'story' I came up with, that all came a bit later, trying to make sense of this image that I originally had of the primes being charged, mutually repulsive, and in motion – or having *been in motion*. At the time, it had felt like, this is profoundly important and I have to act on it, I was being somehow compelled to act on it. It felt like the most important...certainly the *strangest* idea ever to enter my mind. And, insofar as I can grasp what is meant by 'numinous', it was charged with a numinous quality.

I was hoping to be able to actually describe the scheme in serious mathematical terms, to reveal that there was some mathematical integrity behind it, but that never happened...So all I had was this nebulous idea about an evolutionary dynamical system underlying the primes. And it was an idea which seemed very strange, I can't emphasise that enough – I couldn't really justify it using any sort of logical or mathematical reasoning, and yet it gripped me psychologically with such force that I couldn't let go of it, I was driven to try and make sense of it. And that led me to create a website...you know, this is what you do in 1998, you create a website, and then you start emailing various eminent mathematicians and physicists to try and get them to look at what you're doing. And as a result of that, a few people were quite helpful and responsive, I was sent some relevant literature, and I started to realise that actually, there are a lot of strange, unexplained connections between number theory and physics. These things seemed to me to be circumstantial evidence supporting my strange insight, whatever it might have been, or whatever value it might have had. They too suggested the number system had some mysterious 'quasi-physical' character. This may have been wishful thinking on my part, but the material was undeniably fascinating in its own right, so I started compiling it into a web-archive, intended to, at least indirectly, back up my idea. Eventually, though, my original idea began to become a bit of an embarrassment to me – it seemed quite nave and ill-informed. So, as the archiving took on a life of its own, and I became fascinated with all this serious maths and physics that I had become aware of, I gradually buried the original idea inside a vast web-archive. But I never entirely removed it, somehow still sensing, or hoping, that there was something of value there.

All my attempts to come up with a mathematical model, a dynamical system that would correspond to that image, had failed. I had struggled because I didn't have anything like the mathematical abilities that would be required for that. And in fact, I now feel vindicated in that it's not that I wasn't capable enough to do it; in order to describe anything like a flow in this space of Beurling prime configurations wherein what's called the classical prime configuration, the usual primes, constitutes some kind of dynamical equilibrium – in order to describe anything like that you need to do what Michel Lapidus has done, and introduce a noncommutative flow on a moduli space of fractal membranes. And there was no way in 1998-9 that I could have had access to those ideas. So – and again, this isn't a serious proposition, but the only way I can make sense of this for myself – it was as if I'd caught a little precognitive glimpse of some future mathematics, sensed the importance of it, tried to get it down, but didn't have the language to get it down, did the best I could, and put it out on the Web. This then led on to me putting a lot of time and effort into what was effectively public service web-archiving for a few years, which has been quite fulfilling, but it was initially just a consequence of the original 'flash', and the compulsion it induced in me. Now I'm feeling somewhat vindicated that someone appropriately qualified has shown that there does appear to be something like this underlying the number system.

C: Is there an analogy between what you're describing and what happened historically with non-Euclidean space – could it be seen as an arithmetical version of that, with the unknown time parameter as something as unanticipated as the curvature of space?

MW: Yeah, in the sense that you're breaking out of what is considered to be the only possible version of something, into a whole range of possible versions, and that initially seems ‘mad’ to many onlookers.

C: At the time, the idea that space could be folded or that space could be curved seemed insane. Nevertheless, such new generalisations are arguably the very movement of science itself.

MW: I think it was Gauss, Boylai and Lobachevsky who simultaneously came up with the same basic idea of parabolic geometry, and at least one of them was afraid to even mention it to anyone. If I had still been involved in serious mathematical research in 1998-9, if there had been a career at stake, my guess is that, having had the same experience, I may well have thought twice about going public with these ideas. Whereas as it was, it didn’t really matter.

C: An interesting example of how being embedded in a discipline, having a reputation, and no doubt having funding depending on it, would actually stop you from saying something – there wouldn’t be any channel through which to get it out.

MW: In a way, I was in a perfect position to just have a go, to push it out there.

I’ve read accounts of mathematicians trying to describe how they made certain great conceptual leaps. The big difference is that the leaps they made were into something that could actually be mathematically described, and ultimately, you know, were incorporated into legitimate mathematics. Whereas I just had a sort of mad flash, a glimpse of something which, as yet, is not legitimate mathematics, it's just a vague impression.

C: Yet the structural detail in which you described it makes it something more than simply a vague idea.

MW: Well I'm not sure that the *detail* of what I've described adds any validity. Had it not been for Lapidus' work coming along, I probably would have entirely disowned it by now. But at the time, there was a conviction that there was *something* in it, but it was hard to know what to call it. There was an awkwardness because, it falls between the usual categories...I suppose it could be called phenomenology or something, there's probably a legitimate-sounding name that someone could come up with. But when I put it out on the Web I was quite careful, because I was well aware of all sorts of cranks on the Web ranting about how they've discovered this or that revolutionary idea, or proved Einstein wrong, or whatever. And I so I tried to be very understated in how I presented it – you know, I've had this idea, and I don't know what it means, it may well be meaningless, but I invite people to either show me why it's meaningless, or else indicate what it might lead to. And gradually it began to happen. But I don't know if it really contributed to anything. I think Michel Lapidus would probably have reached the same conclusions regardless. Perhaps it did influence him, I don't know, but I don't think so. So in a way, if I did catch a glimpse of some sort of future mathematical discovery, it would have occurred anyway, so what's the value of what I did?

C: At least, it does lead one to think about mathematics not in terms of the points at which people draw everything together, make it into a formal system, but rather these discontinuous moments when, inexplicably, things move, things split apart and something new opens up?

MW: A crack opens up and something doesn't quite make sense.

C: From what you know of the mathematical community, is it the case that the sort of research you are pursuing is not accepted, that they're not interested in it?

MW: There's a small enclave of perhaps slightly more open-minded, more unusual mathematicians, who are prepared to discuss these sorts of things privately. The vast majority are slightly bemused or just not interested, they're too busy with their own work to stop and think about what it all might mean. Mathematicians aren't generally encouraged to think about 'meaning'. They don't really need to, they've got a very exact discipline, they've got theorems to prove and things like that. Basically, what I'm doing, I couldn't call it mathematical research. You've called it fundamental research...you could call it that, I know what you mean. The way I see it I'm just trying to raise certain questions and generate discussion, and I'd say the vast majority of the mathematical community just isn't going to engage with that, which is okay. Because I'm not actually doing mathematics, I'm not engaged in mathematics research in the way they are; I'm playing a different game, asking questions about what mathematics means, what it is, how we relate to it. But at the same time I'm not part of the philosophy-of-mathematics community either, which is involved in something much more rigorous and disciplined than what I'm doing.

I suppose because I've got more time I'm in a better position to just stop and think: what's the point, why are we looking at this stuff anyway, what does it mean? Professional mathematicians these days tend to be extremely busy, they've got to theorems to prove, papers to publish, conferences to attend. They need to keep their careers afloat, and so they've got a lot less time to think about what this stuff might *mean.*

But the thing about the Web – and this is quite an important factor in what I'm doing – is that it's possible for me to say what I think and to discuss it with large numbers of other people in the academic world, without having any formal academic status and without having to get anything published. And I can change it as I go along – there's no final document, that's the other thing. I don't publish articles, I can just put together vague rambling webpages and then keep changing them as my ideas change.

C: This is a striking aspect of your research – the presentation of it is very open: no need to hold back until you've got an completely solid hypothesis and then put it online tentatively as a preprint. The site is continually updated, and you're creating this network which connects together all these scientists who it seems are working on related problems but don't always know of each other: in some cases you're actually notifying them of each other's work.

MW: I've spent a lot of time emailing relevant researchers and alerting them to the existence of new articles or preprints which they may well be interested in. And it's difficult to quantify, but I do seem to have stimulated a certain amount of interdisciplinary work. I've created a rôle for myself which hasn't really got a name yet, and as far as I know, no-one's prepared to fund me, but I'm doing my bit to weave together these threads of research.

Part of what caused my disillusionment with mathematics, which caused me to drop out in the first place, was...well, the overriding impression was the biblical image of the Tower of Babel. It occurred to me that if you were to put the names of all professional research mathematicians in the world into a hat and pick out two, the chance of there being any real overlap in their research interests would be quite small, and this continues to get smaller. It was as if mathematical research was getting so fragmented that there was no longer any effective communication possible. So in a way, I suppose what's needed, if one wants to try and fix this, is people who are not specialising, but rather trying to get an overall picture and to weave it all together by creating lines of communication. I didn't come into this with that intention, but that seems to have been the rôle I've created for myself. I haven't got any answers at all. I just feel that there are questions that are important and which aren't being asked – possibly because there just isn't the language in which to ask them coherently yet. But at the same time, because there are no real constraints on me, I don't have to prove myself to anyone, publish anything, or stay within any particular boundaries, I can just throw out certain ideas, get people thinking about things, suggest connections between things in such a way as to indicate the existence of something which we can't yet pin down perhaps, but which will come into focus the more we look at it.

In the mathematical community, at least the proportionally small number of people I've communicated with, I do get a sense that there's a sense of wonder there which is something unquantifiable, something that you couldn't prove a theorem about, but which is nonetheless there. It's something to do with these individuals' emotional, psychological or even spiritual orientations, I suppose. But a lot of mathematicians, I'm afraid, do tend towards the familiar stereotype of socially inept, almost mildly autistic people who have very little time for the unquantifiable aspects of life. And so there is an almost scathing disregard from some quarters. I think – I feel – that anything that's vague or a little bit ephemeral, they see that as worse than useless, perhaps because their own self-esteem and status is tied up in a self-image of being the guardians of some sort of absolute inarguable exactitude and truth.

C: Your guiding thread is a fascination with how mathematics relates to reality, rather than with mathematics *per se*.

This seems to be related to the fundamental problematic which appears right at the very origin, you could say the co-origin, of mathematics, philosophy and natural science: with the Pythagoreans, who realised that operations carried out on numbers applied – rigorously, but for them somewhat magically – to natural phenomena, and so put forward the idea that reality was actually nothing but numbers, reality was structured by number. In a sense they put forward a type of mathematical empiricism, *i.e.* the idea that you could go out and explore the world, and what you would expect to find was relationships between numbers, and you could understand the natural world like that. Now this came to a catastrophic end with the discovery of irrational numbers...

MW: Yeah, the legendary drowning at sea of Hippasus of Metapontum – it's fascinating stuff, a pivotal event in human history...

C: Certain aspects of the natural world were shown to exceed number – or number as it was conceived then. Certain quantities which can be mathematically described (the diagonal of a square with side length 1, the area of a circle with radius 1, the golden ratio) cannot be expressed as ratios of integers, they are 'alogos' or, as we now say, irrational.

After a long period under the influence of Aristotle's instrumentalism, for which every sublunary physical phenomena was subject to an inevitable degradation, meaning that exact mathematics was applicable only to astronomy, the celestial and sublunary worlds were (blasphemously) reunified, most of all by Kepler, under a single mathematical physics, reinvigorating the Pythagorean dream of a mathematical natural science.

Then in the nineteenth-century mathematics seemed to exceed its reference to the real world, to claim its own autonomous consistency, and any necessary link with the natural sciences was removed, mathematics asserted its independence from any application; its applicability to the physical world even seemed to become a sort of mathematical ghetto.

Now, in the work you're looking at, it seems that we return once again to a Pythagoreanism but with a strange twist...

MW: Yes, something's been turned on its head. I've been fascinated by Pythagoras and the Pythagoreans for a long time. Sometimes I think, you know, in a way I'm acting a bit like a 'neo-Pythagorean'…but as you say, there's a strange twist there. I think a lot of people forget, when Pythagoras is discussed as 'the first mathematician', that he had one foot in mathematics and another one in a sort of shamanic, mystical-type reality.

C: Whereas the Pythagoreans discovered in numbers the semi-divine property of rigorously elucidating nature, we have this experimentally and theoretically-vindicated body of method and knowledge taken from natural science, with whose aid we're trying to illuminate what now seems like a somewhat opaque and mysterious numerical realm; and there are these things within number which still don't really make sense. Mathematicians such as Chaitin [*see article in the current volume–ed.*] have said that mathematics must now become a quasi-empirical practice – this is in relation to his own work, but it might perhaps equally be applied here.

MW: Some of the quotes I have on the site agree: Martin Gardner said something about how some problems of number theory might be undecidable and might need a sort of mathematical 'Uncertainty Principle'. Timothy Gowers wrote that the primes somehow *feel like experimental data*, but at the same time he's well aware that they are rigidly determined.

We find ourselves in a situation where Michael Berry, studying spectra of quantum mechanical systems, can take techniques he's developed to classify or better understand certain types of physical systems and apply them to the Riemann zeros, in order to produce a hypothesis that we will get a particular 'number variance' in the far reaches of the spectrum of Riemann zeros – then years later, you know, computer power reaches the point where zeros can be calculated at that scale, the 'number variance' computed...and the graphs match up perfectly. It's the first time I'm aware of when a physicist was able to tell pure mathematicians something new based entirely on his familiarity with physical systems.

C: Does the field then become *de facto* an experimental one? You have the a hypothetical physical system which will produce the system of vibrations which the Riemann zeros seem to correspond to. And the only way to find out whether there's really any system which is adequate to that would be by experimentation – in the same way that the Higgs Boson hypothesised to glue together the results of quantum physics must now be sought experimentally – hence the construction of CERN's much-anticipated Large Hadron Collider. Does someone have to *build* the Riemann dynamical system?

MW: Michael Berry has said he's absolutely convinced that, if such a thing is physically possible, someone will make one of these things in a lab, and then the Riemann zeros will actually come out on the instrument readings. But at the moment there's no-one actually conducting any experiments which are getting anywhere near that, or even attempting to. You do have physicists taking certain ideas – largely mathematical models intended for physical systems – and applying them to aspects of the zeta function. There is an experimental branch of study of course, you've got people looking at the Riemann zeros themselves, which contain a wealth of data – we've got, I believe, hundreds of billions of them calculated now – this is being done with grid computing[8]. The gaps between them and all kinds of other things you can measure when you've got a set of seemingly random real numbers, are being analysed using a variety of statistical methods, random matrix theory is being applied. So these are, to some extent, experimental studies. Marek Wolf (Institute of Theoretical Physics, Wroclaw) experimentally detected a widespread physical phenomenon called '1/*f* noise' in the distribution of prime numbers.

The prime numbers continue out to infinity, we've known they go on forever since Euclid, but we can only calculate them up to a point. We tend to think our current computers are 'powerful' , and we think we can find 'big' prime numbers – you know, now and again one will even make it into the news. But *there's no such thing as a 'big' number*, this is what I always try to get across to laypeople – because the number system goes on forever, however far we look, proportionally it's still an infinitesimal step into an infinite unknown .

C: And, of course, in consequence, no matter how many zeros are found, one never comes any closer to a *proof* of RH.

MW: Yes, exactly. There's the duality between Riemann zeros and primes, and so the same idea applies with the zeros. We can never calculate more than an infinitesimal proportion of them. Sometimes I use the analogy of large telescopes: you're looking out into space, and the more you can see, the more you can deduce about the nature of the universe you live in. Analogously, we can 'see into' the number line a certain distance, what we think is a 'long way' – but again, it's meaningless, really, to say a 'long way' or a 'big number'. Of course we can see further than we've ever seen before, so we can detect certain apparent patterns which can give rise to hypotheses that we can then attempt to prove. Similarly we can look further than ever up the critical line now, and with hundreds of billions of Riemann zeros we can test certain hypotheses and generate new ones. So there's an experimental element in that. But as far as the hypothesised Riemann dynamics goes, the quest to try and pin down something like a Riemann dynamics isn't really being furthered by experimental science as such, rather the progress seems to be coming from mathematicians like Connes, Lapidus and Christopher Deninger (University of Münster). But these people – well, certainly Connes and Lapidus – do have a very broad interest in large areas of both mathematics and physics, which is what makes their work so interesting.

It would be misleading to suggest that mathematics has become an empirical science, since exact formulations are still possible – even in these more hazy areas – at least we can't rule out the possibility of exact formulations. But an empirical approach has become potentially useful. In connection with this, I should mention the emergence of probabilistic number theory, which in itself raises huge questions. Probabilistic number theory effectively started in 1940 with the Erdös-Kac theorem which I mentioned earlier, the discovery that the number of prime factors in 'large' integers has a kind of random distribution which follows the Gaussian distribution or bell curve. That discovery led to a whole outpouring of theorems and conjectures which have collectively become known as probabilistic number theory, where you apply the methods of probability theory, and make use of the key idea that divisibility by a prime p and divisibility by a different prime q are 'statistically independent events', one has absolutely no bearing on the other. When you deal with probability you deal with this idea of independent events – *well, these are arguably the most independent 'events' there can ever be.* Physical events in any well-prepared experiment, you might think they are independent; but ultimately every particle of the universe is gravitationally pulling on every other particle, everything is linked, although the effects are generally negligible and impossible to quantify. The only place where things are *totally* independent is in the number system – the divisibility of an integer by two different prime numbers. So here is a place where you can apply probability theory, where everything is *entirely* exact, where you can let your n tend to infinity and that actually refers to something. Probabilistic number theory allows you to *prove* things about prime numbers and about the number system generally, using the techniques of probability theory, and that seems highly counterintuitive. The fact that it works at all raises questions which are more like 'mysteries' than formal mathematical problems.

There are three separate areas worth mentioning here: the emergence of probabilistic number theory, the effectiveness of the analogy with statistical mechanics – partition functions, *etc.* which I described earlier – and then the rôle of random matrix theory, which was developed for modelling subatomic phenomena, but then was accidentally found in the 70's to apply directly to the theory of the Riemann zeros. So you've got three separate areas of randomness-based thinking, stochastic disciplines if you like. They deal with large systems which have too many components to keep track of individually – these components must be treated almost sociologically, as populations, and subjected to probabilistic or statistical thinking. All three areas have been effective in furthering our understanding of the number system. Now, again, mathematicians would tend to focus on at most one of these things, see what could be achieved and perhaps make a few sober remarks on what it all might mean. But to me, the fact that you've got these three areas, all of a stochastic nature, shedding light on the primes and the Riemann zeros, points to something very strange. We've got primes, the most basic things in the universe as we experience it – the sequence of prime numbers is the most basic non-trivial information there is, it's the one thing you can't argue with anyone about, it's the one thing all lifeforms in the universe could potentially relate to. And yet in some ways they seem to be best understood using a type of analysis more appropriate to weather systems, roulette wheels, boxes of gas, *etc.*

I've always thought of probability theory as a slightly 'tainted' branch of mathematics for three reasons: Firstly, it's origins are not entirely honourable – I seem to recall that it has its roots in an historical accumulation of gambling techniques which got distilled into a formal theory by Pascal. Secondly, it deals with 'events', repeatable 'events', which are categories of physical phenomena, 'occurrences' of one type or another which can be quantified, measured, counted, numerically analysed, *etc.* whereas truly 'pure' mathematics doesn't rely on anything in physical reality in quite this way. Finally, by its very nature, probability theory tends to deliver imprecise information – there's always a margin of error. And yet this system of thought, which has been developed in order to deal in an approximate way with large, complicated physical systems, seems so perfectly applicable to something which is so fundamental, which is characterised by an absolute precision, and which underlies everything else – the distribution of primes! It's as if we've got something back-to-front. It's similarly interesting that probability should have such a fundamental rôle in quantum mechanics: an ultra-simplified account of what QM tells us is that, insofar as it can be understood as being made of particles, the universe can also be understood as being made of 'fields of probability' . Probability theory in a casino, yes; or in a meterology lab... But prime numbers? The fundamental level of matter? These are things we instinctively feel should be totally deterministic and rigid. And to me, this suggests we're looking at something the wrong way 'round – something's been turned on its head. It's as if 'randomness', or some essential, almost esoteric quality associated with randomness – that quality evidenced in our failure to really understand what we mean by 'randomness' – is emanating up from these fundamental realms. We've been dragging it down from the macroscopic scale, the casino scale, down to this micro-level, in a numerical and physical sense, and finding that it helps us understand something. But I feel something's back-to-front there.

A mathematician called R.C. Vaughan states in one of my archived quotations that it's obvious that the prime numbers are random, but we don't know what randomness is. And there is a real problem with defining randomness. There are several definitions, information theorists, probability theorists, have put forward definitions of what it means for something to be random. The definitions overlap to a large extent, but ultimately, when is a string of digits random? If I give you a block of a thousand 0's and 1's, it might *look* completely random, it might even pass numerous tests run on it for randomness…but then I could reveal, well actually, no, it's a thousand digits of π starting from the two-millionth digit. And then it's not random anymore. So there's the whole question of what randomness is. This is one of the central themes that fascinates me: where does this notion come from, where does it lead us in our understanding of the reality we inhabit, and why does it tie in so closely with both the fundamentals of the number system and of particle physics?

And then there's the difficulty of talking about having two of anything, that in order to have two of anything you have to have a category which those two objects both belong to. But the categories are always imprecise. We have to partition spacetime into blocks with 'fuzzy' boundaries, and then attempt to match aspects of these blocks up with some ideal which exists in a sort of mental hyperspace, a Platonic realm of sorts. So we're projecting these categories onto the universe which actually aren't intrinsic in the universe; we're setting out these boundaries, but the boundaries are blurry. Yet, despite the possible problems this blurriness might cause, on a practical level we're able to then extract data which fits remarkably well against certain probability distributions. The most ubiquitous and I think the most important one is the Gaussian or bell curve – and this, as we can see from the Erdös-Kac theorem, has a mysterious and fundamental relationship with the number system we're using to count members of our fuzzy-boundaried categories in the first place.

The effectiveness of statistical inference in the hard sciences and the social sciences – I'm sure this would be widely disputed, but I feel there is a mystery there which isn't really being acknowledged, and it has to do with how we can name and count anything, and how, when we do name, count and measure things they seem to collectively accord with these ideal mathematical blueprints or templates. That says more about the way our mental hyperspace is being mapped onto the physical universe than about anything *intrinsic* in the physical universe.

C: When you look at the local you expect to find precision, whereas with the global you're happy with statistical data. Here we're looking at these local, precise conditions and there seems to be randomness 'built into' them in a way that's not immediately comprehensible: After all, they're not statistical aggregates in any obvious sense.

MW: Yes, the set of positive integers is in a category of its own, *there's just one number system.* Yet, it's as if this entity – if we take the positive integers, the primes and the zeta function as aspects of a single thing, different aspects of the same entity – rather than being a carved-in-stone, unique thing, is actually just one example of a class of things, and we're able to apply statistical analysis because of that. This is why, when I started finding out about these things, I felt my 'prime evolution' thing might have something in it, this idea of the number system being a frozen state of something which had previously inhabited many different states. I've had certain quite critical, serious-minded people react to some of my more sensational suggestions by saying, well all this number theory and physics, there's nothing mysterious at all – the universe follows mathematical laws, so of course we'd expect certain aspects of number theory to show up in the physical world. If they'd look a bit deeper into this, they'd see what I meant: yes, it's not surprising, given that maths underlies all of physics, that we might get, say, particular values of the zeta function showing up in string theory, or the theory of integer partitions relating to Bose-Einstein condensates or whatever: you get these odd little instances of number theory/physics correspondence; I've catalogued a lot of these in my web-archive. But that's not the really interesting stuff. What's much more surprising is the way physics seems to be pointing the way for understanding the zeta function, and often this is statistical or stochastic physics, as if the zeta function – and in some sense, then, the number system – is just one example of a more general phenomenon. And I don't think anyone disputes the spectral nature of the Riemann zeros now. But it's not one archetypal ubiquitous spectrum we see showing up all over physics. If we saw 'the zeta spectrum' – as it might be called – everywhere, then it would somehow feel a lot less mysterious. We'd probably feel quite comfortable with such an affirmation of the old idea that the number system directly underlies the structure of the physical universe. But the Riemann zeros take the form of an almost disconcertingly arbitrary-looking spectrum, never known of by humans prior to the late 1850's. In the very recent past we've been confronted with the fact that it has all the fingerprints of membership in certain classes, very wide classes, of very specific physical systems, as if it's just one element of a whole class, a population of things. So it's a bit like the way you might be able to, based on the postcode of a UK resident, predict certain things about his or her attitudes, abilities, tastes, whatever – because you've got statistical information about the population, you can make plausible hypotheses about this specific individual.

And it's as if the primes-zeta entity, whatever you want to call it, despite its seemingly fundamental, unique status, is just one individual in a wider class of things. But the space in which that class exists is something we haven't even begun to imagine might exist, or we haven't got any access to.

So we have this image of a frozen system, something congealing into a state, and then…it's as if you walked into a concert hall and caught the last note of a symphony, and everybody's applauding ecstatically and you're wondering, what's all the fuss about? You didn't witness the process that led up to that last note, and it's like, with the prime numbers, we're just walking in on the last moment, the culmination of something. As if there was a whole 'symphony' that led up to that, and humanity may be on the verge of revealing it.

*

C: All of the foregoing seems to suggest that what we think of as simple and elegant foundations may in fact be the eventual product of something which is rather complex, even beyond our comprehension. So we'd have to separate out what seems simple and elegant to us, from what is actually fundamental in the universe, and this is another sense in which mathematics mirrors the condition of theoretical physics, in which, characteristically, the further we go towards the fundamental, the stranger things become (string theory being a case in point).

Rather than defining the primes on the basis of the supposedly fundamental and simple number line, in fact it seems that, when we look through this complex theoretical-mathematical prism you have described, there's actually something more fundamental about the primes. The primes themselves produce...

MW: ...the number line, yes, you can see it that way. I came up with this naïve idea, before I really learned any of the more serious stuff, this was after I had been thinking about the Erdös-Kac theorem, the primes and the Gaussian distribution, but before I 'experienced' the dynamical aspect of the primes. I was thinking about how we tend to construct the primes. We're taught to construct the number line starting with one and then using the Peano axioms, you know, there's an axiom that basically says, whatever number you arrive at you can always add another one to it. And I thought, hold on, where does this come from, this idea that you can always add another one, and I started to question that as something that might not be as obvious as it first seems. There's some hidden assumption there about order, time or something, I felt.

And I thought, well, there's an alternate approach we could adopt here, we could start with an infinite alphabet of meaningless symbols, an infinite alphabet of meaningless yet distinct symbols, and then create the dictionary of all possible words of finite length out of that alphabet.

This alphabet of symbols would correspond to the prime numbers. By combining the symbols in all finite possible combinations, you generate the set of words in your infinitely-long dictionary – this corresponds to the fact that if you combine the primes in all finite multiplicative combinations, you get the set of positive integers. Except now *there's no sense of order*: Because we're not starting with the positive integers, we don't need to think of one prime number as being 'greater than' another. The primes are not embedded in the positive integers yet, they're just these free-floating abstract symbols. So I used to try and conjure up this image of bubbles floating in an imaginary space, each with an exotic glyph, a symbol from our 'alphabet of primes' on it. The idea is that you can then join any number of these bubbles in any combination, including repeats. All possible such bubble-clusters are to be found floating somewhere in this space. Some are larger than others in the sense that there are more bubbles in the cluster – that is, more prime factors – but there's no sense of a cluster coming 'before' or 'after' another cluster. It's only when you cross the Rubicon of deciding which alphabetic symbol is going to be your '2' that you start to create some sense of order.

So I had these hints and intuitions – I couldn't really pin them down to anything very rigorous – that we've been thinking about randomness and the fundamentals of reality in a back-to-front way. We've got ourselves into a kind of confusion where everything seems immensely complicated when we delve down to the fundamentals of either the number system – which seems at least partly to inhabit the realm of psyche – or of the physical world, the world of matter – just open a textbook on analytic number theory or quantum mechanics and you'll see what I mean. I felt this issue could be addressed if we examined some of our 'obvious' assumptions. We think we've taken the obvious construction – that is, you start with one, then you add one, and then you add another one, this idea you can always add another one. Rather, what if we start with the primes, and build the number system up that way? The whole 'order' thing then becomes more of a 'phenomenon' than something axiomatic...

C: Coincidentally, the 'legendary' Dr. Daniel Barker also devised a notation system for the positive integers based upon prime factorisation, which is very close to what you're talking about here.[7] You have these inseparable lexicographical units from which numbers are composed, and they could be in any order. He was interested in place value as a culturally-repressive numerical practice, and this was a way of doing away with place value completely. Each number would just be like a collection of boulders or something.

MW: The lexicographical approach, yes. I've tried to get this across to some lay-people I've talked to. There's the

COLLAPSE VOLUME I Erratum:
p162 Note 7 should read http://hyperstition.abstractdynamics.org/archives/005047.html

fundamental theorem of arithmetic – literally *the most important thing we know about the number system.* And no more than 0.1% the population have even heard of it, I'd guess. It basically says that every integer breaks down uniquely into prime factors. And we've got this strange situation where almost nobody knows this, this simple fact, the most important thing we know about the number system. This is straying into other territory, but to me, humanity's relationship with number is rather unhealthy, because we've built this entire civilisation around the mathematical sciences, and yet the ordinary population knows nothing of the basics, and often finds mathematics a source of fear and unpleasantness. I try and conjure up this image of these bubbles, the fact that the clusters can be as large as you want, you can have huge 'planets' of prime factor bubbles joined together – *there's no upper size limit.* And so something like the greatest common divisor can then be explained very simply, it's just the intersection, literally where the two clusters intersect. The least common multiple can be similarly explained. Prime numbers distinguish themselves from non-prime integers because they are individual bubbles. The integer 1 is *the absence of any bubble*, the empty background space, the blank page in the "dictionary" I mentioned earlier…

And then you imagine stringing the entire set of clusters out in a line according to this 'order' thing, and you start to see that there's a counterintuitive variation in the sequence – you get small clusters, huge clusters and single bubbles all intermingling according to no sensible scheme. And this is the sort of thing that I'd eventually like to push further out into the public domain just to see what sort of effect it would have, when people start looking at their supposedly familiar number system in this new light. Because people tend to think of the number system like a row of boxes of cereal in a supermarket, just identical units stacked together, a sort of homogeneous featureless thing that just goes on: each number is just the previous one plus one, there's nothing much there, nothing of interest. And it was Frank Sommen, a really remarkable, imaginative Flemish mathematician who I worked with during my PhD studies, who once said to me, every positive integer is a different animal. I came to see exactly what he meant: each one's got its own 'anatomy', every one's a different story, and that starts to become apparent as soon as you realise that each integer factors in a unique way into prime numbers.

C: This is a basic intuition that one finds in 'primitive' numerological systems.

MW: Yes, and in children as well, with their favourite numbers, and feelings about each of the first few positive integers – ethnomathematics and children.

C: Something that gets beaten out of people by mathematics: when people start learning mathematics, it's as if the first task is to extirpate any idea that numbers have quality. Mathematics is in fact often seen as constitutively opposed to any such intuition.

MW: Yes. Marie-Louise von Franz, one of my favourite writers, who studied under Jung and wrote a lot about number archetypes, she talked about number having both quantitative and qualitative aspects. The quantitative is obvious, we all use numbers to count. Cultures who revere certain numbers and have mystical beliefs about them which we might laugh at, they still use them to count with and to trade, they recognise that they have a quantitative aspect. This is the aspect of number that has given rise to economics and technology; but equally, perhaps even more importantly, there's the qualitative aspect that only survives in our culture in children having favourite numbers, some adults having lucky numbers, not wanting to sleep on the thirteenth floor of an hotel, the way they might choose lottery numbers, that sort of thing. But, you know, in 'serious' society numbers are supposed to be *entirely* quantitative. Von Franz wrote about a traditional Chinese story involving eleven generals who, faced with some very difficult military situation, took a vote as to whether they should attack or retreat. Three voted to attack and eight voted to retreat. So what did they do? They attacked, because three was a more favourable number – it wasn't a *bigger* number, but it was a number associated with unanimity, or some other favorable quality like that. And the attack was a success.

So it's interesting that they could build a civilisation that was able to have a functioning economy and military and to govern millions of people – clearly they were intensely aware that number had a quantitative aspect – but there was also a serious engagement with the *qualitative* aspect which is dismissed in our present culture as entirely superstitious. Now I'm not encouraging people to engage in completely arbitrary numerology, I mean, I've looked at a lot of that new age numerology literature, and the problem is, nothing can be verified: someone can write a book saying a particular number means something, and someone else can write another one saying it means the complete opposite. It just confuses matters, as there's never any consensus or certainty in these interpretations. That's why professional mathematicians would almost unanimously just react against it and say it's all rubbish.

C: But is there any way to talk about it which doesn't get into that morass of mysticism?

MW: There are two approaches: one is the serious attempt by Jung and his followers to catalogue all of the ethnomathematical systems, undertaking a serious study and survey of various cultures and their relationship with number, trying to find common threads, and through psychoanalytical work and dream studies, trying to find extract essential patterns to build up a body of material from which we could possibly deduce something about how number interfaces with the psyche at a fundamental level. The other approach is to seriously study number theory, because as far as I'm concerned, that *is* numerology, really – you're looking at the properties of integers, and if you study it to a certain depth it takes you into the realms of what you could only call the mystical or the uncanny, where cracks seem to open up in your normal understanding of reality.

C: Is that perhaps what characterises number theory as opposed to mathematics, what makes it a very different discipline?

MW: Well, number theory is universally acknowledged as a branch of mathematics. It can't really be separated from it like that. But it arguably has a unique status at the very heart of mathematics. You're working at the very root of it all, dealing with the simplest objects, the positive integers. And yet you come across these counterintuitively complicated structures and results. You can separate mathematics into branches and disciplines but they all ultimately overlap and interrelate. Gauss (who himself was called the 'prince of mathematicians') called mathematics 'the queen of the sciences', and number theory 'the queen of mathematics'. The idea is that number theory is generally seen as the pinnacle, in that it contains the most difficult problems; also it's concerned with the integers, and all of the rest of mathematics ultimately relies on integers. Hence it's not surprising that problems of number theory do seep into other areas of mathematics, and even physics. What *is* surprising is that physics is beginning to shed light on number theoretical structures like the zeta function, as if it were just one of a class of objects, whereas it's meant to be this fundamental object underlying everything.

What I'm trying to describe with my clusters of bubbles isn't intended as any sort of serious mathematical proposition, it's just a picturesque visualisation – trying to look at the number system from another angle, if you like. But there's a hidden assumption within the Peano axioms, I think, which needs to be addressed – although I don't think I'm the one to address it. It concerns the axiom which allows you to always add one. Even in the proof of the infinitude of primes, I sense some sort of subtle circularity there – the idea is that, if the number of primes were finite, you could multiply them all together and then add one. And that rapidly leads to a contradiction concerning primeness and divisibility…hence there must be infinitely many primes. So that takes you back to the Peano axioms, the idea that you can always add one. But in my visualisation, multiplying them all together would correspond to building one mighty cluster using one of each type of bubble. And in that visualisation 'adding 1' is a far less obvious operation. This ties in with problems of time, the idea of time, repetition, even basic physical questions: you know, this 'adding 1' business presupposes that you've got a physical space, something like the space we're familiar with, in which you can make a sequence of marks, or a time continuum in which you can make a sequence of utterances or beats. And I feel there may be subtle assumptions concerning the homogeneity of time and space involved in this, too.

C: These questions of time and space must fall out from the primes' intimate connection to the relationship between multiplication and addition.

MW: Brian Conrey, who's President of the American Institute of Mathematics, and Alain Connes have both been quoted as saying that RH is ultimately concerned with the basic intertwining of addition and multiplication. And if we haven't really got a clue how to prove RH – which we don't – we're going to have to own up, we don't even understand how addition and multiplication interrelate. A more succinct, precise way of describing these two possible constructions of the primes that I have outlined – the conventional 'just add 1' approach, and my 'lexicographical' approach with its equivalent clusters-of-bubbles visualisation – is given by Grald Tenenbaum, who certainly knows what he's talking about:

> Addition and multiplication equip the set of positive natural numbers with the double structure of an Abelian semigroup. The first [addition] is associated

> with a total order relation as it is generated by the single number one.

So if you've got addition and you've got this single number 1, you can generate the postive integers just by adding 1 plus 1, 1 plus 1 plus 1, etc. If you take 1 as your 'additive generator', the universe generated is the set of positive integers.

> The second [multiplication], reflecting the partial order of divisibility,

This probably isn't the time to get into the subtle issues of 'order' in mathematics – you've got 'total order' and 'partial order': addition relates to total order, where something definitively comes before or after something else; and divisibility relates to partial order, a less distinctive type of order, although I won't get into the details of that…

> [Multiplication], reflecting the partial order of divisibility, has an infinite number of generators, the prime numbers.

So, now, rather than starting with just the number 1 and combining it with itself in every possible way using addition, we start with this infinite set of primes and then take all possible *multiplicative* combinations.

> Defined since antiquity, this key concept has yet to deliver up all of its secrets, and there are plenty of them.[8]

---

[8] Tenenbaum and France, *op. cit.*

It has the quality of a square peg in a round hole, this tension between addition and multiplication. It's almost like, despite the inarguable perfection of the number system, they don't really fit together very well, and they generate what I feel is something like friction, and this produces the sprawling mass of definitions, theorems, lemmas and conjectures that we call analytic number theory. There's a novel by Apostolos Doxiadis called *Uncle Petros and Goldbach's Conjecture* – it's written as fiction, but he gets some key ideas across through an elderly mathematician character. This is very well put, I feel:

> Multiplication is unnatural in the same sense that addition is natural. It's a contrived second order concept, no more really than a series of additions of equal elements.[9]

So that's the point, that 3x5, you can see that as 0+3+3+3+3+3 – you start with nothing, zero, and add three five times. So in a sense you can build multiplication out of addition, whereas it doesn't work the other way around. So addition is a first order operation, and multiplication is, as he's saying, unnatural, in that it's 'second order'. The thing that struck me about it when I was dwelling on this for a while was that it has to do with *time*, it has to do with repetition. And it also relates to the very deep issues concerning the whole idea of where number comes from and how we define number. As I hinted earlier, I've spent a lot of time thinking about how you could ever have two of anything. You know, there are two people sitting here in this room right now, but that relies on the definition of what a 'person' is. We define the category linguistically, and we think we know what a 'person' is, but you can imagine some sort of genetically-engineered mutant that may or may not be a 'person' depending on how the definition was formulated, and the definition's made of words and each word is imprecise, is subject to interpretation. So any type of category you define is going to have a 'fuzzy' boundary, so...although it works quite well for day-to-day affairs, counting things works fairly well, you've got fifteen sheep in your paddock. But you can always contrive some convoluted situation where, maybe it's fourteen sheep or maybe it's fifteen – is that odd looking creature really a 'sheep' or is it something else?

---

[9] Doxiadis, A. *Uncle Petros and Goldbach's Conjecture*. NY: Bloomsbury, 2000.

So, it comes down to issues of language and definition. We consider chunks of spacetime, we recognise patterns and say, yes, that chunk of spacetime falls into such-and-such a category. As I said, I started to wonder how you can really have two of anything. Every entity ultimately distinguishes itself from every other, these categories are not mathematically precise, there's an arbitrary element involved in deciding whether things get included – "where do you draw the line?" as they say. And yet these categories are the essence of counting, and if there's a problem with applying the concept '2' to our experience then there's going to be a problem with all of the other positive integers.

Exceptionally, when you get down to the subatomic level you can have two of something, because each individual electron is absolutely indistinguishable from the others. So that's interesting, that this concept makes sense at the subatomic level but then 'fuzzes out' at macroscopic scales.

But the thing is, when you say '3x7', you're effectively saying 'three sevens'. So, seven pebbles in a row – you count out seven by adding one plus one plus one, etc. That feels quite 'natural'. But then, to make the leap to 'three lots of seven'…you can have three giraffes or three potatos, the fuzzy boundaries mean that's a difficult enough issue as it is, but 'three sevens' presupposes that a 'seven' is *something that there can be more than one of* in some sense...

C: One would have to say that the multiplier and the multiplicand are somehow of a different order, two different types of numbers are involved in the operation.

MW: Yes, one is operating on the other. If you add, it doesn't matter...I mean, it's true to say that 3x7 is the same as 7x3, you've got this basic 'commutative' property applying to the positive integers. But when you consider the 'act' of 3x7, the three is how many times you're doing something, whether it's laying out a row of seven beans or playing seven drumbeats, and the seven is some kind of an extension in space or time. Whereas in adding

3+7 or 7+3, both numbers play the same rôle. So there's something there, not easy to pin down, which we don't understand, and I have a very deep sense that we won't really understand it until we really understand *time*. It has something to do with time. Our inability to understand the primes, our inability to prove RH is a symptom of our inability to understand the relationship between addition and multiplication, and that is related to our relationship with time.

C: On your site you quote J.J. Sylvester:

> I have sometimes thought that the profound mystery which envelops our conceptions relative to prime numbers depends upon the limitations of our faculties in regard to time, which like space may be in essence poly-dimensional and that this and other such sort sort of truths would become self-evident to a being whose mode of perception is according to superficially as opposed to our own limitation to linearly extended time.[10]

MW: I think he must have been thinking about the relationship of multiplication and addition in terms of time. This was 1888, so RH had been posed, but mathematicians long before RH understood that the enigma of the prime numbers was rooted in the uneasy relationship of addition and multiplication. So possibly he had a sense that the relationship had something to do with time. But he says 'the profound mystery which envelopes our conceptions relative to prime numbers' – in other words, the puzzling interface of addition and multiplication – 'depends upon the limitations of our faculties in regard to time'. So if there were a higher dimensional, a two-dimensional 'time surface' or something like it – the word 'superficially' is being used by Sylvester in the original sense meaning 'relating to surfaces' – our minds, normally constrained to a 'timeline', could perhaps 'spread out across it' in some sense. It's perhaps a bit like being able to come up off the surface of the earth and look down from a third dimension to get a sense of how things are laid out, whereas when you're stuck on the ground, certain things are not at all apparent...but these are all very vague and intuitive ideas.

*

C: In one of the papers you link to in the archive[11], Volovich suggests a most extreme and startling explanation for the concurrence of physics and mathematics.

MW: Yes, and you may have noticed that he quotes Pythagoras at the beginning, a slightly amusing Greek-to-Russian-to-English compound translation of "all is number" – "the whole thing is a number". I got very excited when I first found that paper, because he's suggesting that number theory is the ultimate physical theory. That came out in 1987 as a preprint at CERN – he's an accomplished physicist – but it was never published in a journal. The fact that it never got published and the fact that he hasn't responded to my questions about it could suggest that he's backed away from it somewhat. I can't speak for him, but I wonder if he's slightly embarrassed by its more grandiose claims, in the way I was suggesting earlier that physicists and mathematicians can be.

---

[11] I.V. Volovich, "Number theory as the ultimate physical theory", Preprint CERN-TH **87** 4781-4786 (1987)

But the thing is, he has done this vast body of work on *p*-adic physics, which I referred to earlier. And the rise of *p*-adic physics is a very interesting thing in itself because, you see, even though the universe at the scale of this room is Archimedean – I can lay my ruler end to end and will eventually reach the end of the room – the universe is *not* Archimedean at all scales. Below the Planck scale, it's no longer Archimedean. Below this 10^{-35}m or so – which to some people sounds too small to worry about, but you just take a metre, then a tenth, then a tenth, not that many times, really…It's not that our instruments aren't precise enough to measure below that scale, it's that the whole idea of measurement as we've formulated it ceases to make consistent sense. And effectively, space becomes non-Archimedean below that scale. There's a similar scale with time and other fundamental quantities, below which they become non-Archimedean. You can theoretically join some unit of measurement end-to-end and never achieve a given, finite extension.

This has led people to think that maybe *p*-adic physics, where you're dealing with a non-Archimedean number system, would be more appropriate for application at the sub-Planck scale. And Volovich seems to be suggesting that different non-Archimedean number systems could apply to different regions of space and time at different scales. Again, I'm not entirely sure: large parts of the paper are beyond the scope of my present understanding. I'm intrigued by his referenced to 'fluctuating number systems', but I don't know whether he means fluctuating with time, or in some other more generalised sense.

People are now starting to think about applying *p*-adic mathematics to the physical world. Each *p*-adic number system provides a different sense of 'distance' between two rational numbers, and that notion of distance then allows you to define all the other numbers which aren't rational via precise mathematical concepts involving 'limits'. I mentioned this earlier. This distance or 'metric' is defined in terms of divisibility of primes. It has to do with highest powers: for instance, in a 7-adic metric, finding the distance between two rationals involves basically looking for the highest power of 7 that divides into the numerator of their difference – that difference of course is also a rational number – when it is expressed as a fraction in lowest terms. As a result of that, number theory comes flooding into your *p*-adic physics: if you start looking at *p*-adic or adelic space and time, issues associated with the prime numbers become directly relevant. Of all of this number theory/physics material I'm archiving this is the area I'm least familiar with.

C: Saying that the means of measurement, that the possibility of measurement has changed is one thing, but saying that numbers are actually the 'atoms' themselves, so to speak, is something else: that means that there is no longer some *thing* you're measuring. The measurement itself takes on a sort of substantiality.

MW: Yes, these are very difficult notions to grasp, in so far as I understand what's being proposed. I think, perhaps like myself, Volovich caught a glimpse of something, got quite excited about it and wrote it down; he's quoted Pythagoras – it's as if there's some mystical quality to his insight.

C: There might be thousands of these papers hidden everywhere that people haven't published.

MW: I'm not sure it would be in the thousands, but who knows…There's a general hesitance to stick one's neck out. If I'm helping to encourage that sort of thing, then I suppose that's a useful contribution.

C: Exeter University has granted you an honorary fellowship and hosts the web- archive, but there is no funding available for your work. Apart from your own fascination with the subject, what drives you to continue this labour of archiving and making your own speculative connections public?

MW: Over the years after I'd dropped out of formal academia, I spent a lot of time thinking through and honing these ideas about mathematics being some sort of inner priesthood of our scientistic culture that's in the process of destroying the ecosystem, and wondering what could be done about it, how do we change this, you know? I felt that campaigning to stop the destruction of this or that rainforest isn't going to be enough, you've got to go right to the core, to the root of the problem, the fulcrum. And, reading von Franz, with her ideas about ethnomathematics, and quantity and quality, and reading René Guenon, who – although I don't embrace his traditionalist fundamentalism – wrote a fascinating book called *The Reign of Quantity and the Signs of the Times*, I started having this idea that only when Western Culture re-evaluates its relationship with number can there be any real change in the way we relate to the world, because we've got stuck in a 'quantocentric' view of the world. And so I have felt at times that what I was trying to bring forth – whether it was in my strange 1998 'evolutionary' notion or just in my networking of various people's work via my web-archive – was an acceleration towards an imminent transformation in our relationship with the number system. I was quite driven for a while, but I've become considerably more cautious and sober in my approach to this since. I saw what I perceived to be clues...felt that it *had* to be coming, and only through that sort of transformation will the Western project ever be able to steer itself in a less destructive direction. At times I've felt that I had an important rôle to play – not that I was 'chosen' to do it or anything, but that my work was cut out for me, and it was an important mission. Other times, I've been much less certain, and wondered, you know, why am I sitting in front of this computer editing HTML, when I could be spending the same time and effort campaigning for, say, the rights of an indigenous tribe having its land ravaged by a multinational corporation. I had to justify this to myself when people I knew were involved in things like that, by telling myself, well actually they're just dealing with the symptoms, whereas I'm trying to deal with the root of the problem. So it verged on an idealism, almost an activism.

C: The point being that rather than lamenting the destructive rôle of number and of science, one tries to recognise that there's something else within number, and as you said, to re-evaluate our relationship to it, which is not to say to reject it, but to become *more* numerate...

MW: Yeah, which is what I saw around me, people being very suspicious towards mathematics, hating it, seeing it as controlling and evil, and I thought, no, we need to get inside it, try to understand where it comes from and how it works.

But then I started to question whether I was just creating a whole set of complex and noble motivations for myself when in fact it was just my ego or desire to be acknowledged for what I'd achieved, or, you know, just wanting some sort of recognition or status. I was continually wondering what it was that was motivating me, and trying to rein myself in and consider the worst possible motivations as well as the best.

I had a kind of motivational collapse in early 2005, when I was struck by a very deep sense of there being insufficient time; you know, I had this grandiose hope of helping to effect some sort of long term change in culture and the way in which we deal with the number system. I started to think, maybe what I'm contributing to *would* have that effect if there were a few more centuries left of relatively leisurely culture and well-funded academia to take these ideas on and develop them, but, you know, we're facing multiple global crises, and this sort of thing is never really going to have time to take root.

I've since drifted in and out of this activity periodically, found what I think is a healthy level of interest in these matters. But I don't strongly believe that I'm part of some current of cultural change anymore, I'm just...I suppose you just can't know what effect you're having, particularly with the Web, when you're pushing ideas out. You don't know who's reading them and what they're going to do with them – a bright teenager who reads my website might be inspired to study mathematics and, influenced by some of the hints, clues, suggestions, *etc.* I've assembled, go on to make amazing discoveries...who knows?

There's also the whole relationship between psyche and matter which seems to have been at the centre of all my interests over the years. I got involved in parapsychology for a while, online psychokinesis research in 1996, wondering whether there really was something in that, and what it would imply concerning the psyche-matter interface. There's also a very exciting interdisciplinary field of 'consciousness studies' emerging, and which I've been following, people trying to understand the physics of consciousness, looking at microtubules in brain cells and how quantum mechanical phenomena at that scale might help to explain the origins of consciousness – physicists, neurologists, philosophers, psychologists, anthropologists, psychopharmacologists, *etc.* are all contributing to this field. Then there's all the Jungian theory concerning myth, archetype, synchronicity and the 'psychoid' level of reality – a kind of psycho-physical interface. The simple fact that mathematics is able to describe the world at all, that's a mystery involving mental constructs being mapped mapping onto material reality. There's the 'mind-brain problem' which philosophers debate. And then dreaming, shamanism, schizophrenia, quantum-mechanical paradoxes, these are all things I've spent a lot of time thinking about, reading about – generally wondering how it all fits together. And it had occurred to me that these topic cluster around the central mystery of how matter and psyche interface. But I'd been thinking about prime numbers, etc. for a few years before it occurred to me that this is very much part of the same picture. I'd been exploring the interface of physics – which concerns matter, obviously – and number theory, which, as that Tenenbaum quote suggested, is really an exploration of 'the mind itself'. And the research I've been interested in archiving displays a two-way traffic: Number theorists have been providing concepts and structures which physicists have used to better understand the world of matter. Physicists have been able to, using their understanding of matter, shed light on the internal workings of the number system. Even number theory *without* the physics is implicated: although number is widely considered as a mental construct, at the same time it manifests directly in the world of matter: when you consider a quartz crystal or a five-petalled wildflower, it's hard to deny there's an essential 'sixness' or 'fiveness' there. So, number itself is a bridge of sorts between psyche and matter.

This last idea, that number is a bridge between psyche and matter, comes quite close to something Jung was exploring in his later career. He left a lot of incomplete work when he died, and I believe he left von Franz to look at number archetypes. He'd looked at individual integers, the first few integers and their various associations. But later, more importantly, he'd come up with the idea that, not individual numbers with their associations, but the *set of positive integers as a single entity* is in itself an archetype, the archetype of order.

Now what has distinguished Western culture from the rest of humanity, what characterises the Sumerian-to-Babylonian-to-Greek-to-Roman-to-Western-European cultural current that dominates the planet with its measurement and science and so on, is the way we've dealt with this archetype which normally inhabits the collective unconscious. I picture it as a sort of mysterious sea creature – we've hooked it and we've hauled it out from the dark depths into the daylight of consciousness. We've taken something that was primarily unconscious, and which would naturally manifest primarily via the number archetypes and number associations in other cultures. We've dragged this thing out of the sea and onto the land, cut it up and studied it, studied its anatomy in great detail in order to obtain a new kind of magic, if you like, and that, I came to believe, was the root of all the world's problems.

But then we have this emergence into consciousness of the set of the prime numbers buried within the set of positive integers, a hidden archetype within an archetype, a kind of chaos within order, the black dot in the yin half of the yin-yang symbol; the emergence of *that* archetype – the prime numbers, the zeta function and everything they entail – into mass consciousness, is just starting now, really. The first four 'popular' books on RH have all come out in the last couple of years...it's strange that this should all be happening so suddenly. Thinking along the quasi-Jungian lines I've sketched out, the integration of these ideas into consciousness, the idea of the Riemann zeros having their origins in some 'older' or 'deeper' numerical reality, something more ‘primordial’, *etc.* may turn out to be of profound historical significance. According to the insanely optimistic wishful thinking which I’ve since distanced myself from, this could be the event that would start to alleviate the effects of rampant ‘quantocentrism’ and put things back into balance.

C: I wonder whether the growth of ‘popular science’ could play a rôle here – thinking in particular of the many books which have been published on RH.

MW: The fact that you’ve got four books on RH out suddenly – why is this, why hadn’t this happened before? I’m sure a few years ago most people involved would have said that it’s impossible to explain RH to lay-people. But four authors have done their best, with varying degrees of success. The books have all been well-received, have sold fairly well. So why is this happening? The mystically inclined might invoke an unseen force that’s trying to bring these ideas into consciousness. Jungians might talk about ‘compensation’ and the collective unconscious. But more simplistically, more materialistically, it’s market forces, it’s capitalism, and it’s because people are looking for meaning. Many are turning to New Age cultism, some are turning to born-again Christianity, Scientology, fundamentalist Islam, whatever. But there are a lot of people who are aware that the real ‘guardians of truth’ these days are not priests and monks, but scientists and mathematicians, and yet, they find themselves in a position where they don't know anything about the essential subject matter. So they want someone to explain, say, the mysteries of quantum physics to them. I get this all the time, people really wanting me to explain quantum physics, fractals, relativity, the golden mean, chaos theory, p; there's a handful of things that people get really excited and obsessed about, you know. And of course the market system rises to meet a demand, a growing demand for meaning. The problem is that capitalism doesn't care whether a book is accurate or well-written, it just cares about sales figures. So as a result you get gross oversimplifications hitting the market and sometimes selling quite well. Because the market has expanded, there is more competition, and ideally, if you believe in the effectiveness of capitalism, then the 'best' stuff will float to the top – but 'best' in this sense doesn't necessarily correlate with truthfulness or accuracy, rather with how successfully the book quenches readers' thirst for meaning. There does seem to have been a certain amount of progress, though. I don't really watch much TV, but it does now appear that with the computer graphics available, it's possible to make some things a lot more visually accessible, so viewers can at least get a flavour of the problem, or of what's at stake.

But the really deep stuff, the major philosophical problems underlying maths and physics…it's hard to imagine that there really is a shortcut to years and years of disciplined study. I mean, you might be able to get the basics of something across to a few, a small section of the population who are already interested and whose minds are structured in a certain way – it's not to do with levels of intelligence, just a certain kind of intelligence. You've got committees for the popular understanding of science and things of that nature, but they're very marginal. Unless there were a major cultural shift, unless you had major government funding, and the top layer of mathematicians and scientists committing themselves full-time to bringing this stuff through into popular culture...but there's no motivation for that to happen – governments aren't interested in educating their populations except in ways which will further economic growth. They want a certain proportion of young people to be trained up to be economists, accountants, engineers, *etc.* 'Truth' doesn't really come into it. So I doubt it…but, again, you never know, some major cultural shift could occur where the demand for this sort of knowledge reaches the point where the best people would feel obliged to provide it. Or, possibly, there could be some sci-fi type breakthrough involving direct brain-to-brain knowledge transfers, you know, you can't rule these things out, but I'm not holding my breath!

You've probably noticed, part of my website is very formal-academic, the web-archive aspect; and part of it is just about getting fundamental ideas across to people who are open to them and just want to understand their reality a bit better. I have felt in the past, with my 'activist' hat on, that it's important to bring some of these issues to widespread public attention – the basic issues of the number system. At this stage I don't know if it *is* 'important' or not, but I'd be very interested to know what the overall effect of that kind of exposure would be. Again, I suppose I am still gripped by the idea that, if we transform humanity's relation with number, that could have a positive transformative effect. I suspect I'm still partially motivated by that belief at an almost subconscious level.

The only thing I can really say with any confidence at all is that I think we're on the verge – and again, the timescale is very indefinite here – but Western Civilisation is on the verge of collectively realising that the number system is something very different from what it had previously thought it to be. I haven't got a particular theory about what it is, I just know it isn't what we think it is.

Introduction to ABJAD

'Incognitum'

ABJAD (ابجد) is an acronym derived from the first four consonants of the Hebrew/Arabic/Persian alphabets; *Alif, Ba, Jeem, Dal.* It is a simply-constructed but functionally-complex alphanumeric system condensing different belief-dynamics from Near- and Middle-Eastern cultures, which became particularly prominent after the rise of the *Shi'a* religion in Iran. Arabic ABJAD originates from the Semitic family of scripts.

In working with Arabic ABJAD usually three numeric values (the ABJAD value of the letter, the order of the letter in the ABJAD table and the alphabetic order of the letter in the Arabic alphabet) are used as numerating values; the most interesting and complex products of ABJAD are those operating with more than one numeric

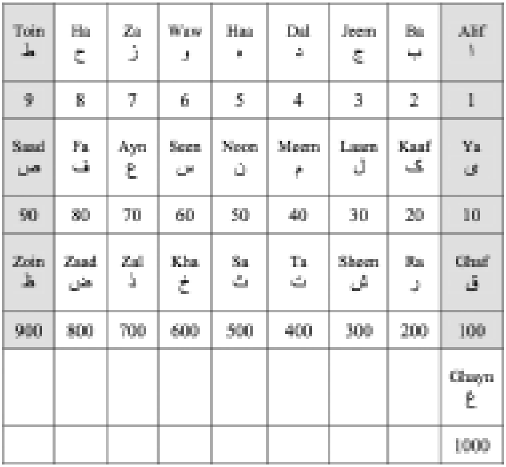
http://www.urbanomic.com

value (i.e. ABJAD value, ABJAD order and Alphabetic order simultaneously) but later works by ABJAD scholars from Iran, India, Afghanistan and Arabic countries show an inclination towards a unified ABJAD value called ABJAD-e Kabir (Major ABJAD).



Toin ط	Ha ح	Za ز	Waw و	Haa ه	Dal د	Jeem ج	Ba ب	Alif ا

								Ghayn غ
								1000

Fig. 1. ABJAD Table (*ABJAD-e kabir*: major abjad)

The arabic ABJAD table (ABJAD-e Kabir) is arranged in powers of 9:

Level 1. *Alif* (= 1) to *Toin* (= 9)
Level 2. *Ya* (=10) to *Saad* (= 90)
Level 3. *Ghaf* (= 100) to *Zoin* (= 900)
Level 4. *Ghain* (= 1000)

The ABJAD values of all levels are based on the connections between the ABJAD order and the ABJAD value of each letter at the first level (1-9), where the

ABJAD value of each letter is equal to its ABJAD order.

LEVEL 1: from 1 to 9. Take the letter *Haa* as an example: its ABJAD value is based purely on its ABJAD order *i.e.* 5=5.

LEVEL 2: from 10 to 18 (ABJAD order). Since the level changes, there is a phase transition from one- to two-numeral values (using one '0' as a place holder). The ABJAD order of the letter *Noon* (under the letter *Haa*) is 14, which can then be numerically simplified as 1+4 = 5. The single numeral x is converted to xx to indicate the letter *Noon*'s location on the second level. Consequently we have 50 instead of 5: 50 is the ABJAD alpha-numeric value for the letter *Noon*.

LEVEL 3: from 19 to 27 (ABJAD order); on the third level xx changes to xxx; the letter *Sa* is under the letter *Noon*; its ABJAD order is 23: 2+3=5=500 (xxx)

LEVEL 4: at this level ABJAD diverges from the power of nine. This might be considered the apogee of the ABJAD alpha-numeric progression.

The numerical arrangement of ABJAD into four alpha-numeric layers, three of which are built upon the power of 9 (9-based) is strongly in accordance with the unique politics of Islamic apocalypticism, whose allegiance is not to sectarian ideologies but to the explicit text of the Quran, immutable according to Islamic scholars. We have three levels (1-9, 10-90, 100-900) whose structures are numerically never concluded (they never reduce to One, remaining imperfectible and inconclusive). Only the letter *Ghayn* numerically stands on its own plane as 1000 (Kabalistically reducible to 1); however, the One here is external to the 9-based arrangement of ABJAD: In Islam, the divine constantly remains on the outside; it is characterized by its radical externality to its multiplicative creation, and conceived not as conclusion or *telos* but as externality. This only serves to highlight the overall imperfectability and inconclusiveness of ABJAD/Creation. The Divine loiters on the exterior (beyond the threshold of ontological possibility) even on the Day of Apocalypse (as in Islamic Apocalypse, *Qiyamah*). God never reveals itself (*Apocalyptio*), shifting the radicality of its exteriority and the inconclusiveness of its creation to another plane.

> While God was the exclusive source of the revelation to Muhammad, God himself is not the content of the revelation. Revelation in Islamic theology does not mean God disclosing himself. It is revelation from God, not revelation of God. God is remote. He is inscrutable and utterly inaccessible to human knowledge [...] Even though we are his creatures whose every breath is dependent upon him, it is not in interpersonal relationship with him that we receive guidance from him.[1]

The ambiguous monotheistic structure of ABJAD (enshrouding obscure religio-political inclinations), and its empathy for imperfectability, multiplicity and

---

1. Edmund Perry, *The Gospel in Dispute: The Relation of the Christian Faith to other Missionary Religions* (New York: Doubleday, 1958), p155.

inconclusiveness, unillumined by a rabid exteriority ungraspable for Man, has made ABJAD the alphanumeric system most favorably-disposed to heresies and obscure apostasies. It is no exaggeration to say that the history of Islam has been perpetually accompanied by ABJAD exploration and alphanumeric distortion of all forms of official and established religious institutions and texts (the latter being untransgressable, and consequently prone to the generation of profound heresies). "Everywhere that ABJAD can be found, a heresy has already emerged," remarks Abidulah ibn-Maymun, the founder of the *Ba'teni* – later to become *Ismailie* – cult.

Given the fact that the syncretic configuration of ABJAD scriptures as well as ABJAD diagrams has always been complemented by the sheer syncretism of its redactors and exegetes, their usage in mass culture and belief systems of Muslim populations has sprawled over a vast array of everyday affairs, surpassing mere occult instrumentality and elitism. In the timeframe between the rise of *Horoufi* sect (from which the most prominent ABJAD theorists rose – 9th Century) to the *Qajar* dynasty (1781-1925) ABJAD diagrams were composed for purposes including education in elementary schools to depict the interactions between alphabet, numbers and religious matters in an efficient way (commonly being used for memorizing religious stories, names or even basic mathematical or linguistic lessons), interpreting the Quran and other Islamic or sectarian scriptures, healing diseases, invoking love or hostility, conjuring deities, operating as catalyzer-spells in alchemical experiments, *etc.*

The multi-functioning (heretical) nature of ABJAD also allowed it to be extensively employed as a language of communication between minorities (or within minorities)[2], and as an instrument for supporting the political belief-systems of Islam's non-Apocalypse through mathematics, astronomy and geometry and through the cross-fertilization of these fields with linguistics, cipherology and occultism, producing a vast field of crypto-sciences or heretical knowledges. ABJAD has become an example of a numerical system which, far from being a nomadic numerical machine, intrinsically operates within the State in order to initiate anomalous reciprocations (in the case of ABJAD, the state and numbers go hand in hand).

ABJAD Diagrams are perhaps among the more well-known productions of the heretical knowledge and absolute syncretism one finds in ABJAD systems, yet they remain unexplored. They critically condense and compile wide varieties of monotheistic and non-monotheistic elements, although they constitute elements specifying their connection with the minority belief-dynamics of either *Sunni* or *Shi'a.* At the top they usually include the number 786 which alphanumerically equates to *Besmellah-e Rahman-e Rahim* (*In the name of Allah, the passionate, the merciful*), the opening verse of each chapter (Sura) in the

---

[2] In fact, all sectarian ciphers in Islam and Islam-inspired religions are constructed and can be only deciphered by ABJAD.

Quran. The diagrams are mostly constituted of humanoid figures with bodies in positions evidently inspired by the Zurvanite, Sumero-Babelian and Zoroastrian cartographies of blasphemy, or demographic configurations. Archaeological explorations of Near and Middle Eastern cults (especially from the time of the Mesopotamian civilizations to the end of antiquity) reveal that forms of demonism ('demons' being understood as avatars of the outside) are mainly characterized by their anomalous cartographies – diagrams which present the bodies and positions of the demons, and the arrangement of their appendages (faciality is the least significant aspect of Eastern demonolatry. Islam also forbids the 'facialization' of religious figures and martyrs):

- The right hand upward and the left hand downward is a cartography of demonism of the greatest archaeological provenance, originally emerging in the Assyrian period, where demons of pestilence and contagious epidemics are presented as seen in the bronze *Tablet of Disease* (in the collection of M. De Clercq). A significant number of ABJAD humanoid diagrams maintain this cartography in the most explicit way (see page 202) while presenting the ABJAD numbers connected to the legion of the damned and blasphemous people mixed with holy names and numbers on their bodies.

- From stretched hands, one pointing to east and one pointing to west, we can identify solar demons (the Romans ironically borrowed this same diagrammatic position from the Babylonians in their crucifixions, the most prominent of which are the iconographic portraits of the crucified Jesus). (See page 200).

In ABJAD diagrams, when it comes to the divination of a religious figure, facialization is achieved through composing the face, head and body with the exclusively use of numbers and letters, with no depiction or explicit portrayal (see page 201). In consequence, ABJAD pushes Islam's holy ban on facialization into a blasphemous demonic complexity which with the same reprobate enthusiasm tears itself away from the expressionist hegemony of facialization.

In these diagrams each part of the body (including the head) has its own agenda of ciphers and exclusive numbers. Usually most of the body is enveloped and takes the form of a repetition of the letter *Haa* (ABJAD value = 5) representing the five individuals of Shia: Mohammad, Ali, Fatemeh, Hassan, Hussein (see page 201).

In western occultism, diagrams and magic squares are usually surrounded by magic circles and other geometric shapes which are always closed and symmetric. Their task is to converge the power of the spell upon a certain objective. In ABJAD diagrams these circles are replaced by open geometric shapes such as triangles and curves conducting open-ended and divergent experiments in syncretism. In ABJAD diagrams these curves and shapes are commonly known as ABJAD shields. Most ABJAD books, although published by *Shi'a* authors and containing the names of *Shi'a* Imams, correspond to the cipherology of the traditional Arabic ABJAD in which diagrams or figures are guarded by ABJAD shields, covered by either the letter *Meem* or the letter *Dal* (the first and the last letters of the name Mohammad); the design of these traditional ABJAD shields is of two intersecting lines forming an acute or obtuse angle representing the letter *Dal* (ABJAD value=4). Unlike in *Sunni* ABJAD (see page 199), in *Shi'a* ABJAD these shields are not pointed and, rather than the letter *Dal* are in the form of the letter *Ha* – expressing the *Shi'a* politics of *Taqiyya versus* the *Sunni* politics of conflict in *Jihad* – but with curved lines diagramming the calligraphic elements of the letter *Haa*. These curved lines usually become overrun by the repetition of the letter *Haa* (ABJAD value = 5) on their outer surface, standing for 'Panj Tan-e Aal-e Abba' *i.e.* Mohammad, Ali, Fatemeh, Hassan, Hussein who are the pillars of Shia (See page 210).

Page 199: A spiteful spell for calling upon a disease or replacing a fatal disease with a less dangerous illness. The word *Allah* constitutes the outer open circle, the targeting-arrow of the letter *Dal* (empowered by the outer circle and representing the power of the prophet Mohammad) can operate from the opening and directing the power of the ABJAD square (composed by the numerated name of a disease) in the guise of a sting towards a person.

Page 201: The Arabic and Abjad equivalents of the words 'No' or 'Closure' compose the face of this ABJAD figure, making her mute, blind and deaf or, symbolically, easy to be controlled. At the center of this ABJAD diagram is an ABJAD square which has replaced the heart. The symmetry of numbers and certain words (the word speed and the name *Ali*) make this spell oscillate between negative and positive intentions. This spell should be engraved on four pieces of alloy (fusion of the senses), buried in soil, put in fire, exposed to wind and thrown in water to make a person possessed by an involuntary love.

Pages 204-205: An Abjad diagram for memorizing the names (unique characteristics) of Allah in an interacting form.

Existential Risk

Interview with Nick Bostrom

The Future of Humanity Institute forms part of the ambitious research program of the 21st Century School *established by benefactor James Martin at Oxford University in the UK. If it is surprising that the UK's most traditionalist university by reputation should host an interdisciplinary research institute dedicated to evaluating the long-term prospects of the human race, it is perhaps even more remarkable that the director of the Institute Nick Bostrom began his academic life in analytic philosophy. He talks to* COLLAPSE *about the wide-ranging research program of the FHI which seeks to address 'existential risks' for mankind ranging from natural catastrophes to biotechnical modification and the emergence of nonhuman intelligences.*

COLLAPSE: The establishment of the Future of Humanity Institute seems to mark one of those 'crossover' moments where strands of research that once

COLLAPSE I, ed. R. Mackay (Oxford: Urbanomic, September 2007)
ISBN 978-0-9553087-0-4
http://www.urbanomic.com

seemed purely academic, or were at best categorised as interesting 'thought experiments', are becoming pragmatically pertinent: amongst the issues you deal with are bioscience, cryogenics, catastrophes of an ecological and cosmological nature. Is the function of the Institute to liaise between the academic research environment and various public policy, governmental, or security bodies who are looking for ways to gain traction on these issues?

Nick Bostrom: Yes, but its primary mission is a research mission – to try to improve our understanding of three broad areas. One is human enhancement, ethical issues especially related to that, but also practical issues, policy issues. The second is global catastrophic risk; and the third area is methodological problems and issues that crop up when we're thinking about the big picture for humanity, both in relation to the first two areas and more generally when we're thinking about anticipated future technologies, and so on. So the primary focus is to improve understanding through research in those areas, but it has a component – or will do, in the future – of liaising with policy-makers and trying to create some public awareness and stuff like that.

So the interdisciplinarity is not an end in itself. It's just that when you try to address some of these problems and issues, it just so happens that more than one discipline is needed.

C: Given the magnitude of the problems you're proposing to treat, is it surprising that there hasn't been such a unified initiative to tackle them until now?

NB: I don't know, it's difficult to do within a traditional disciplinary setting, that's one reason. Because none of these problems fit neatly into a discipline. So it might not be so surprising that it hasn't been done, because it requires probably some framework that goes outside traditional disciplinary boundaries. In one sense it is surprising because the issues are important enough that one would have thought that humanity would have a few people somewhere thinking about them: extinction risks, for example. So, from that, from the observer from Mars perspective, I think they would be surprised.

I should also say that although these three areas are quite a broad range, in reality what it means is that one would have to pick specific, tractable questions within those areas, and look for opportunities where analytic methods and our current knowledge actually enable us to say something.

C: You were trained as a philosopher, and we were struck by the fact that the Institute is attached to the philosophy faculty. How did the Institute originally come about?

NB: I was in the philosophy faculty, I was a postdoctoral fellow. And I've always been interested in, been pursuing, these kind of questions. And together with Julian Savulescu, who is professor of practical ethics here, we had a couple of ideas for research projects, or programmes that we wanted to pursue or get funding for. One of them was human enhancement ethics, another global catastrophic risk, and there was a third one. So we went to the development office, these are the people responsible for fundraising in the university, to see if they had any ideas. And they said that they knew someone they thought would be interested in this, and had actually mentioned me to him before. It turns out this is James Martin, who is the benefactor for the James Martin 21st Century school, of which the Institute is now a part. And James Martin had interviewed me earlier, about a year before, for some television documentary he was doing, and appeared to be quite enthused about what I was trying to do. So by sort of coincidence – because I didn't know that he was a donor, or a funder, a rich man, at that point, he was just somebody doing an interview – this development guy managed to put one and one together, and establish some contact, and then there were lots of drafts back and forth, and lots of different proposals, and discussion, and this is what resulted in the end.

C: So, with the involvement of Martin, is it actually a genuinely philanthropic exercise?

NB: Yes – we have some co-funders as well, but that's where the bulk came from. And Julian Savulescu, he's the director of the Uehiro Centre for Practical Ethics, downstairs in this same building, but he also has a programme on Ethics and New Biosciences, which is also part of the James Martin 21st Century School.

The whole James Martin school is really James Martin's attempt to do a couple of things: to encourage interdisciplinary work and to bring Oxford into the 21st century, but more specifically to try to get Oxford to focus on some major problems for humanity in this century and see what practical solutions can be found. The whole school to some extent is shaped by that vision.

C: How closely would the Institute's research have to track or monitor things like ongoing developments in, for example, AI research, and even A-Life research? Different research programs underlie both of those, with internal technical debates that would have ramifications for broader questions about the nature of other intelligences and the characteristics they would possess.

NB: There will be one level of monitoring which is just keeping some general idea of what's going on. But then depending on which specific projects or which specific paper you're working on at the moment, you would obviously then have to dig down very deeply in that area. So if you were writing a paper on artificial intelligence let's say, then you would have to get up to date on the latest details of that. But generally you can't be up to date on the details of everything that is possibly relevant, it's just not humanly possible. So you have to have some general idea of roughly what's happening, and then you get to focus, like I say, when you're producing something specific.

C: Are there practical limits? If the Institute expanded its staff would you be able to have these subcategories…?

NB: Yeah, you still wouldn't be able to keep track of everything, but you could have people specialising more, or covering a greater range of topics. We're still in the bootstrapping phase now.

C: What seems remarkable is that you're trained in analytic philosophy, and you're applying the methods of analytic philosophy to problems which up until now have only been thematised in so-called continental philosophy, i.e. the problem of death, the problem of what it is to be human, etc. And yet within your programme you seem to be pursuing these problems in a way which continental philosophy has been unable to do. For example despite its obsession with the concept of death continental philosophy doesn't seem to have tackled the basic fact that when the sun expires we will all die – and what the consequences of that are for thought.

NB: I think there is a traditional view that the continental philosophers have all the interesting questions whereas the analytic philosophers have had the right answers but the boring questions…I see philosophy as on a continuum with science really, I don't make a sharp distinction. It's the more general end of the spectrum, things that haven't yet been crystallised out, specialised into different particular sciences. And so whatever seems relevant material to thinking about the particular problem questions, I think that's what one should use. And also in some cases even though the questions might seem the same they might actually be different. So although continental philosophers might have thought a lot about death, there are lots of different questions you can ask about death: about its meaning for the artist, or for the human being on one hand, or you could ask more concrete questions such as whether current research priorities make sense, is the allocation of research money to biogerontology versus cancer research in the right proportion, for example.

C: How do other philosophers – not only at Oxford but also elsewhere – regard your work?

NB: Some of the work I've done has a sort of dual-use function, which is the way I have had to work up more or less until now, since I haven't been able to have a post full-time for doing this. So some of the papers like *Infinite*

Ethics or *Are we Living in a Computer Simulation*?[1] can be read by people who are really interested in the FHI from a purely philosophical point of view, and there is enough in it for them that even if you're not interested in the practical dimensions of it you'll find some worthwhile philosophy there. But from my point of view the reason why I've written about them is that I think it relates to this broader vision, to the practical concerns that I have. So one could find some of these stepping stones where one could get both philosophy and the relation to humanity's future down on the same paper, but it requires a little bit of picking and choosing and figuring out clever ways of combining the two. It's obviously much more desirable if one can do work solely on the basis of the criteria that it should be relevant to the big picture for humanity.

C: You propose to tackle analytically problems which are of such cosmic scale that they induce what you call in your own work 'infinitarian paralysis': that is to say, given the magnitude of these questions, how is it possible to do select one path or another, to choose between options? One of the methods you seem to be using is the quantification of risk, a risk-management or risk-assessment approach. This quantitative treatment of risk is something which is of great importance in public policy, in corporate policy, in finance, but how is it applicable to these massive existential dilemmas?

---

[1] Both at http://www.nickbostrom.com

NB: Well that's a relevant question, whether it is or not. Specifically, in the case where you have literally infinite stakes – which is the case this paper, *Infinite Ethics*, discusses – there is a set of ethical theories that run into trouble when you take seriously the possibility that either the universe might be infinite and have infinitely many people in it, or even that our actions might have infinite consequences. Even if you think the possibility of that is small, you're still going to have what I call this 'infinitarian paralysis' problem. It seems as if it's impossible that we could make a difference, in terms of changing the expected value of the world. Now, that might be more a problem for certain ethical theories rather than for humanity, because if certain ethical theories have that implication then we might just take the lesson that we should have other ethical theories instead that avoid it. So I think it's a significant but technical point. There is a broader sense in which it's possible to think about some of these things. It's easy to get a sense of vertigo sometimes, because there are such extremes in terms of the best outcomes and the worst outcomes, just the sheer magnitude of them: the problems and the stakes are so much larger than things that people spend so much more time thinking about. But my view is that one should try not to look away, one should just try to keep a steady gaze, and use the same methods, as much as one can, use the same analytical rigour, sober analysis, and step-by-step investigation to make progress on these.

C: Is the long term proposition of the methodological approach that you will actually be able to answer ethical questions relating to these 'existential' issues on the basis of quantitative consequentialist ethics? Myron Scholes, for example, created a formula for quantifying risk in financial transactions: do you propose that such a thing is possible in ethics, or do such methods only give guidance for further thinking about the problem?

NB: Yes, I think it's one ingredient, I think there is more to ethics than risk analysis. In terms of a meta-ethical view or a foundational view, I'm not firmly committed, I'm still trying to figure out which meta-ethical framework is correct, I don't know. Certainly I think taking consequences into account must be at least one thing that any reasonable theory would do, but there might be other things in addition, and how you should take them into account. So the answer would be no, I don't assume that would be the be-all or end-all. I think it would be one useful piece of information to have, if you could have that: information about the risks and the expected utility of different actions, I certainly think that would be useful. Really, the value proposition would be to try to illuminate some aspect of the big picture for humanity, pretty much those aspects where it's possible to illuminate them. Some might be very interesting, but would need some new insights that nobody else had, to figure out how we could say anything intelligent about them – maybe it's just not possible given current knowledge. But then there are some aspects where, with hard work or ingenuity, or using techniques of various kinds, we can say something that is not obvious and yet is relevant. So it's shooting for those targets of opportunity...

C: That's what you mean by 'opportunistic research'? Choosing the problems you think you can gain some traction on.

NB: Exactly.

C: Prior to the methodological question, it seems, are certain fundamental underlying assumptions which are driving the research, amongst which are the ideas that longevity is a good thing, that survival of the human race is a good thing: and the optimism of the 'transhumanist values'[2] that you personally espouse go beyond this.

NB: In terms of the first one, longevity, my view is that increased longevity and great health, or people having the option, would be a good thing. So that's my view, it's not necessarily a premise of all the work that the Institute will be doing. But that's the sort of question the ethics of which would be a subject of enquiry. It might turn out also not to be a yes-or-no thing, it might under certain circumstances be a good thing, under other circumstances it would be problematic. If other researchers looked at it maybe it would not be…and so whereas I am personally quite enthusiastic about the prospect of healthspan extension that's not a premise for the Institute. Now as for the survival of humanity, could that be seen as a premise? Well it's not an unquestionable premise, you could have a philosophical seminar where you would discuss that, and indeed we have had such a seminar, papers have been written discussing whether that would be a bad thing or not. So it's certainly discussable. Now if the work moved more into liaising with policymakers then I guess it would be hard not to make some assumptions like that. I mean, it's just as when you have someone researching cancer they just assume that it's good if we can find a way to detect breast cancer early, you don't have to have a huge philosophical conversation about that.

---

[2] See 'Transhumanist Values' at http://www.nickbostrom.com

C: But precisely from a philosophical point of view this becomes a problem: It's not that one needs to denounce the fact that philosophy liases with the world, tries to engage with practical problems. But isn't it problematic that the 'transhumanist values' seem to have a basis in a particular political (and implicitly, philosophical) position already – *e.g.* when you talk about the 'entrepreneurial spirit' being part of the set of values?

NB: But you've got to keep distinct transhumanism and the FHI. There are other organisations – the World Transhumanist Association and so forth. That one in particular is not so much a specific philosophy but a conglomeration of different people and thoughts and values, some of which I disagree with; but obviously I am a transhumanist in a certain sense. But the FHI is not an institute for transhumanism or anything like that. What it does though is to focus on problems that would be of interest to transhumanists and many other people as well, I mean obviously global catastrophic risk would be of interest to a transhumanist, but so would it be to many other people. And similarly with the implications and ethics of new technologies. So there again, you can have different perspectives and viewpoints and arguments, which might or might not agree with certain transhumanist positions.

*

C: In several of your papers you talk about the possibility of transcending 'observer selection effects'.

NB: Yes, observer selection effect is a kind of distortion of our thinking that occurs when the evidence we get is filtered in a certain way. The easiest way to explain it is a selection effect that we find in many contexts: there is the fish example where you catch a hundred fish from a given pond, and they're all larger than six inches. So you draw the inference that probably the smallest fish in the pond is not less than six inches. Then you look at the thing you caught them with, this net, that can't actually catch smaller fish. So you realise that although you have one hundred data points, they're all filtered through the selection effect that the net introduces. So, once you realise that you have to correct for it, if you want to estimate the population of fish in the pond you have to take that into account. So there are different methods for doing that in standard statistics. Now, an observation selection effect is similar, except it's not introduced by limitations in our measurement apparatus – the fish net – but by the fact that all observations require there to be a suitably-positioned observer to make the observation or to build the measurement instruments in the first place. In many cases these are not really relevant, but there are certain specific questions and problems where observation selection effects become crucial: in cosmology for example, they are of critical relevance when one is trying to figure out what observational predictions one can derive from current inflationary cosmological models. Also, if you ask certain questions about the evolution of intelligent life, they become relevant again. The probability of us discovering extra-terrestrials: they turn out to be relevant to answering that question. And then they are relevant to others, like the probability of catastrophe. And to a number of philosophical thought experiments as well, like the 'Sleeping Beauty' Problem.

C: So our analysis of the possibility of certain events depends on a prior 'transcendental analysis' of the human cognitive condition?

NB: I wouldn't go so far as that, no. But let me give you a particular example. There has been some concern amongst people who are doing these high energy particle accelerator experiments that – it seems unlikely – but theoretically maybe they could cause a breakdown of the metastable vacuum state, which would mean that there would be a rip in space-time that would expand at the speed of light in all directions, and bring utter disaster not just to earth but eventually to the whole observable universe. And so the question is, what reason can we have for thinking that these things won't happen?

The director of the Brookhaven particle accelerator commissioned this report a few years ago, the Brookhaven Report, to study this potential risk. And the authors of the Brookhaven Report made a good point, that the energies that would be attained in the reactor when particles collide, are attained all the time in the atmosphere: there are cosmic rays, particles from space that hit molecules in the atmosphere. And they occur much more frequently there. So, assuming that the reactor events are equivalent to the naturally-occuring ones, we can then calculate an upper bound on how probable these reactor disasters could be, and it's very reassuring if you do that.

Now one problem here is, how do we know that the natural disasters are not very common? Suppose it were the case that on average, taking an average cosmic region, that it was usually sterilised after one day, so you would have this furious destruction of cosmic regions, and then nothing else would happen. Now how do we know that that's not the case? Even if that was the case then we would still obviously expect to be alive – you don't observe these destructions, the destruction hits you at the speed of light, so no-one can see these things. So the only thing that would be seen would be parts of the universe that survived. And if the universe is big enough there would always be such parts. And so they had overlooked that. But it turns out that you can get around that, and this is a recent paper in *Nature*[3] I wrote with Max Tegmark, who is a physicist, where we point out that you can use data from planet formation rates to place an upper bound on this. The basic idea is that if these sterilisation events had been very common, then we should have expected to have been on a planet that had been formed much earlier. So there you can, using these data, and awareness of these observer selection effects, find a way round it. In this case it supports the original conclusion.

*

C: As is the nature of the research undertaken under the aegis of the Institute, issues about the possibility of some posthuman intelligence, non-carbon-based life – there's a high degree of philosophical speculation, or abstract speculation, involved in these. On what basis would you discriminate between relevant and irrelevant degrees of speculation? For instance, after the 'singularity', this unimaginable amplification of cognitive capacity, there's an issue about whether there would be any continuity between intelligence as we know it, as familiar to human beings who are organic entities with a set of organic interests, and some sort of massively distributed non-organically-individuated intelligence. Would it have the same kinds of interest, would it want the same things that carbon-based lifeforms want? These are massive issues, obviously. But what's the cut-off point where you foreclose speculation?

---

[3] 'How Unlikely is a Doomsday Catastrophe,' at http://arxiv.org/abs/astro-ph/0512204

NB: Well I guess there are a couple of ways in which it could satisfy the relevance criteria. One is that the question might have independent philosophical significance, philosophers often use thought experiments to test different philosophical positions – the 'brain in a vat' experiment, it's irrelevant how likely it is that scientists can actually make a brain in a vat if you want to think about internalism or externalism about mental states, for example. So obviously anything that is relevant apart from its empirical possibility would fall into that category. But then there are issues that are important because they might have practical relevance to what we should do now, or to one of the main questions that the Institute will study, but where it's just not possible to get anything better than a speculative answer. So then again, my view is that we'll have to make, and use, whatever tenuous guesses we can make, but then simultaneously recognise them as being tenuous guesses.

Because there's not going to be a vacuum here, and if one doesn't try to do something carefully, with qualification and with as much precision as one can, then people are going to do something there anyway, which is going to be less good. So that's one way in which it can be relevant.

And then there are some theories that would be very speculative, and where you might not be able to say that's what's going to happen, but you might be able to say if this thing happened or that thing happened then you can construct a quite good argument for why a third thing would happen, so there might be these conditional results as well. So given certain assumptions and premises you can make a strong case that there would be these other consequences. So that's the third way. To some extent one knows it when one sees it, if it seems to – even if it doesn't prove the point, if it sort of seems like an intelligent, carefully thought out, worthwhile consideration, then that's a kind of useful study.

C: Might some of the questions concerning superintelligence or a transhuman intelligence not be beyond our analytic capabilities? Why would a higher form of intelligence be something that would be recognisable to us any more than human intelligence is recognisable as such to an insect?

NB: If I could answer this in a personal capacity, what I currently think about it is that a superintelligence may be best thought of as a very powerful optimisation process, which means that whatever its goals are, the defining characteristics of a superintelligence would be that it is very good at achieving those goals. So that means that what it would actually do, how it would manifest itself, would depend critically on what its goals were. So the effects might be anything from being totally invisible to tiling the world with paperclip factories or smiley faces or whatever. You might imagine some unwise AI programmer in the future, when they are just about to create this first superintelligence, who thinks it would be very good to give it a motivation system based on reward learning. So they train it to get a reward whenever it sees a happy face, a smiling human face, then if the humans seem happy it gets rewarded for that, so it gets a motive to perform those actions. And then once it becomes more intelligent then it realises that it can produce this outcome that it has been taught to find desirable much more efficiently just by creating lots of smiley faces. And if that's the only goal it has then it might work out a very clever way of achieving a maximum of smiley faces. So I think with something that would be radically superintelligent – not a human that is slightly smarter than us, or AIs in the near future, but a really radical superintelligence – I think it could be very alien, and one shouldn't think of it as a sort of human genius.

C: This indicates another fundamental issue, the question of whether intelligence is necessarily connected with goals or aims. One could say that human intelligence precisely has this excessive problem-solving capacity without having a particular aim, or at least the former exceeds the latter to a comical (or tragic) extent. Is intelligence necessarily goal-directed? And if a superintelligence emerges, will it emerge from somebody explicitly setting out to build it? Might it not emerge instead as something which has not been planned at all? If you think of the Internet, or something like Google, an intelligent system that has in a sense developed a model of meaning, of how words are connected together, couldn't something intelligent emerge from that without it being planned?

NB: To some extent on the first question, one might think that if a superintelligence turns out not to have any particular goal, then it might not do or amount to very much, and then its just a matter of waiting until sooner or later some superintelligence arises that has these goals and then you would get one of these scenarios where the outcome might be very good or bad, it would all depend on what the goals were. Another kind of answer to that question is that it just depends on how you define goals. So if you just have some thinker just sitting there and looking at the world and pondering it you might think that they have some sort of internal goal, of having their thoughts more highly organised, or thinking true thoughts or something like that.

And as for the second question, it's difficult to say.

There are three cases, there is one where somebody deliberately sets out to build a superintelligence, and then there is the other case where it just would arise spontaneously from the Net or something. And then there could be intermediate cases where people set out to build something but then it goes farther than they imagined it would. If some sort of self-improving system is created, they might not really have clearly envisaged what the outcome would be, but nevertheless you could get a superintelligence out of that. Now which of those is most likely is difficult to tell. Some people think that deliberately setting out to do it is likely to get there much sooner. You might do a comparison with other things, like you don't accidentally build a car or an aeroplane.

C: Are there particular technologies which you think the emergence of other forms of intelligence is tethered to?

NB: Better brain-scanning technology. Well, we can create thin slices of the brain, but then scanning those slices more effectively than we can today, in an automated fashion, in a scalable way. I think that's a real enabling technology. Of course computing power, generally, that's another.

C: But isn't that again to assume that any intelligence will be modeled on human intelligence? Or is that the only assumption that can be made?

NB: No, but it's one way we can imagine getting there: we know one intelligent system, the human brain, it's a physical system, with neurons and stuff like that. So in principle if we could figure enough out about this system then we could see how it does it and do the same thing on a computer. Now it might not be the thing that would get us there most quickly, it might be better and easier and more effective to do it based on other approaches that don't really follow the human mind closely. And for those other approaches I think computing power would be one thing that helps. But since right now the theoretical problem of how to program any sort of system like that is very difficult, and I think progress in neuroscience and/or uploading is a potential technology that could help.

*

C: The Institute seems to belong to this notable category in the post-industrial world where research programs that seem to be completely unconnected to any pragmatic problems suddenly become crucial. Prime number research, which related to a pure mathematical problem, suddenly became the locus of massive financial investment when cryptography became an crucial commercial factor. The last few years have obviously been boom years for certain Islamologists, who suddenly find themselves in great demand by media and intelligence agencies alike, and so on.

Given that philosophy has such a huge wealth of material that is apparently 'useless', one would have thought that its time was overdue…Are there corporate or other interests outside the university who are interested in your research, who see that this extremely long-view research, with a necessarily philosophical component, has important consequences for them?

NB: My own background is that I'm a philosopher but I also do other things apart from philosophy, so it's sometimes hard to see which of these is in play, especially in the catastrophic risk area: I've done some consulting for some intelligence agencies, some stuff like that. Corporate, I haven't really tried to reach out to that yet, it might happen in the future. But the things that are directly relevant to corporations tend to happen anyway, because they tend to have money and they make them happen. The things that don't get done are things that might be of great concern for humanity as a whole, that our species would do well to invest some effort in thinking about. But any particular corporation, it's not their responsibility or their benefit. Like human extinction risks, which corporations are unlikely to fund! But nevertheless it seems like a good thing. So I'm trying to do those things which should be done but aren't being done.

*

C: The mass media plays a huge role in transforming the perception of risk; is there any space in what you're doing to think about the role that that mediated reflection of the risk plays in transforming culture, and the consequence that fear of risk can be just as significant – if not more so – than risk itself? Obviously if you think about the supposed War on Terror and everything that's involved there, these factors are as important as the risk itself.

NB: I agree with that. There is one additional way in which thinking about perceptions of risk might be involved, in addition to the way the perceptions themselves make things change in the world: there is a genuine objective risk, and then there is people's perception of that risk. And if you can study the process between these, the sort of distortions that occur, the fact that there are certain types of risks that people might overestimate because of they are vivid, and are played out in the media; and others they might tend to underestimate because they happen bit by bit on an everyday scale and are more abstract in some way. Now, if you could figure out exactly what those distortions are, for the cases when you can both know the objective risk and people's perception of it, then you might look at another case where the objective risk is unknown but you can still study people's intuitions about it, and maybe you can extrapolate back to get a better estimate of what the real risk is, by a sort of counterbalancing for these known biases. Especially with regard to certain existential risks, I think that's a useful thing to study. And there is quite a lot known about people's risk perceptions, and the biases and heuristics we use to assess probabilities of things. It's also known that our intuitions about those things are wide of the mark, that there are systematic distortions.

C: Aren't humans constitutively non-rational agents? It's impossible for us to right our perception of risk completely, isn't it?.

NB: It's a question of more or less closely approaching. Take weather forecasters, they're pretty good, they're well-calibrated. Calibration is when you say, if you think there is a ninety percent probability of something happening, then ninety percent of the time when you say that, that thing's happened, that's what calibration means. So it doesn't mean that you're right all the time when you guess, but your confidence matches your real knowledge. So weather forecasters are trained on this, you go through lots and lots of examples when you're trained, so they're quite well-calibrated. Pretty much everyone else is ill-calibrated, maybe there are other specific groups that are calibrated, insurance brokers or stock market speculators. So it's possible, given enough feedback and enough incentive, to become a better calibrated risk-assesssor. But that doesn't seem to happen spontaneously or naturally.

C: Bayesian analysis could be applied here, since it includes a measure of confidence in probability calculations.

NB: Certainly. With a lot of the biggest risks, you have to rely a lot on subjective opinion. There's just no way around it, you can't quantify a lot of these disasters that have never happened in the world. The probability that humanity will create a big war with nanotechnology some time later this century: you can't run a frequentist approach and count the number of times this has happened in the past. You don't have a solid scientific model like in quantum mechanics, where you can calculate and get probabilities out, so what do you do? Well, you have to think about it, what would the capabilities be that advanced nanotechnology would make available; how would that play out in a strategic context in the world with competing powers. You think about these things, you discuss with other people, you critique arguments back and forth, but in the end you're probably going to have a situation where different people who are intelligent, who have now read all of this, will assign different probabilities. And I think that's unavoidable.

C: So you do have to work with a synthesis of the facts that you can represent statistically and the knowledge of people's reaction to these statistics.

NB: Yeah, so when we have solid statistical data then obviously we use that. But most of the questions that are of most interest to humanity you can't solve by exclusively relying on that. And that's not just when you think about the big picture of humanity, but when you think about policy, political decision, or indeed your own life decisions: if you decide you're going to marry this person you've been together with, there is no formula or deductive proof that this is the right thing to do, you just have to follow your gut feeling, after having taken into account the obvious objective knowables, then you just have to make an assessment. But that doesn't mean there aren't better and worse ways of doing it. You can certainly be foolish or wise, and different people might do these things differently well. So just because there is a subjective component doesn't mean that there are no constraints.

C: Is it possible for a human being to calibrate themselves in respect of risks on a cosmological scale? If we were truly able to take into account the futility of being a human being on earth, we wouldn't ever do anything – wouldn't that be the truly rational response to these sort of questions?

NB: Futility…well, I suppose it depends on what your measurement scale is. So if you do assign equal value to all life, or all humanlike beings, and you think that a non-futile action is some action that changes the total value, then you run into problems if the universe is infinite. Although there are technical issues there, which my paper *Infinite Ethics* covers.

C: The use of non-standard analysis.

NB: Yes, and it gets very difficult. But suppose you have a different criterion of what's futile or not. So you might think something is worthwhile if it makes you happier, and some people you care about, and people on earth are not harmed, and perhaps helped a little bit, and a few hundred children in Africa are surviving. I mean, these are quite big outcomes from one perspective.

C: But the question still remains of the independence of philosophical thought, and whether in this endeavour there are certain assumptions that have already been made, illegitimately. For instance, if you were to produce a paper which said simply, the rational thing to do is to despair, there's no point in doing anything, that would obviously be bad for the Institute – aren't you automatically disposed to a sort of philosophical optimism?

NB: No, I don't think so. Certainly if someone came up with a good argument that it doesn't matter what we do, or that we're all going to go down the drain, then that would certainly be a paper that would seem very relevant. I mean, I've written some papers which, although they're not quite saying that, could…the *Infinite Ethics* paper doesn't quite say that, but it's going in that direction. *Existential Risks*[4] doesn't say that we're going to be extinct, but it certainly takes that possibility very seriously and argues that the probability is significant. The big picture is difficult. We haven't really thought about it, and one shouldn't be surprised if there are some rather unexpected things once one has started to think about it, that would come out of that.

---

C: Is it possible that the more interesting, the more demanding ethical questions will arise precisely from the position of despair rather than from the assumption that the human race is a good thing, that it's a good thing to live longer? You're asking a tougher question if you say that the sun will expire, and with it all human life – now, how should one act…it's a more profound ethical question.

NB: Well, I think the sun will expire, and we want to know how we should act now, so I suppose that's the question I'm asking in a sense. Although you want to make it more specific to be able to get something out of it. But I think in general whenever you do some kind of reseach project you have some kind of starting point. Maybe one starting point and then you see where you end up. Now for an Institute you can have more than one starting point, for each paper you write you might have a different starting point, and each person might have a different set of background assumptions.

C: The pessimistic view would be that for evolutionary reasons, there's a fundamental mismatch between human beings' requirements, their psychological requirements, what they would need to have to make them happy, and reality: Freud basically says he's a pessimist because, as a result of our evolutionary, our biological legacy we are doomed to be perpetually dissatisfied. Would that have ramifications for you, given that you say that a superintelligence would be a superoptimiser, would such a superintelligence be able to overcome this mismatch between needs, requirements and the capacity of reality to meet them?

NB: With a superintelligence that could be one scenario, you could have a 'Santa Claus' superintelligence scenario, where you have some wish-granting thing. You might have a similar thing without superintelligence. In a certain sense that's what technology is – it increases the ability of humans to realise their desires. Things sometimes backfire, people sometimes have conflicting desires, and you get war and you get pollution. But there is also something more specific, which is that even if, and to the extent that, that's how humans currently are – we're not designed to be happy, but to maximise inclusive fitness on the African savannah, which is very different – it doesn't imply that that's the way we will, or should, remain forever. Which is the transhumanist perspective, that human nature itself is something that humans can change. And certainly this points towards an area of interesting questions.

C: If humanity is going to actively shape its own future, its own destiny, it would have to presumably make some choices, make some selections about the kinds of desirable characteristics it should have in order to change itself so that it can be happy. This goes back the question of the 'transhumanist values': those values have obviously been selected on a partisan basis, they relate very strongly to a certain political position.

NB: I wouldn't say so much a certain political position, in the sense that there are people with all different politics in transhumanism, from social democrats to libertarians. But it's certainly true that the transhumanist perspective is one distinctive take, a specially-valued take on some of these things, and not everybody does or should agree with that. But in terms of humanity choosing, that's one scenario where you would have humanity as a big entity making co-ordinated decisions. One might question the desirability of that, but even more perhaps the probability of that, in the sense that right now there are lots of groups of humanity that are making their own decisions.

C: The conception of humanity acting as *an* agent.

NB: Yes, it's very problematic, I agree with that. If you think like that, you will miss out certain, maybe quite likely, possibilities: there are these effects that arise when you have competition between groups; we might do something that we all know collectively might lead to disaster, just because it's difficult to co-ordinate. Arms races are a good example of this, they're good for nobody but they're hard to avoid. So you might get a different set of possibilities if you had a world government or some kind of very powerful UN in the future that could make co-ordinated choices than if you have a situation where you have multiple nodes of power that act independently.

*

C: Some of the scenarios you're talking about are the stuff of science fiction movies. To what extent are you yourself engaged in a sort of science fiction? Is it a matter of our having to tell ourselves these stories which extrapolate from the state of technology in our society, the things we know we can do, in order to come to terms with the massive risks that are the necessary corollary of every new technology?

NB: I don't know, I'm not a great science fiction reader, or watcher, I'm afraid. Clearly a lot of people find inspiration in science fiction. I think it's both good and bad. It's good in that it might make people aware of possibilities or of future worlds that they hadn't thought about, and it can serve to stimulate people's imagination. On the other hand I think it might distort people's intuitions, because there is a constraint that all science fiction you read or watch has to satisfy – it has to tell an interesting story, so you often have heroes rescuing the world, you have dynamic struggles with human-like characters playing a key part, and determining the outcome. But that's not necessarily the most likely way for things to happen. If you're going to constantly read these, it probably shapes your expectations. If it's all filtered through what I call the 'good story bias', then that can actually warp your thinking.

C: Writers like Greg Egan have dealt with biotechnology, AI, and so on, in a way which certainly doesn't conform to that stereotype.

NB: Yes, I think he's certainly one of the exceptions, I should read more of his work.

C: Science fiction does indeed stimulate people to think about the world and about situations they hadn't thought about; are you not providing a similar service to people who possibly don't read science fiction, providing the same necessary service of widening the scope of people's everyday thinking?

NB: Maybe, I don't see that as the main thing that I'm aiming for, but maybe that's a good effect. Widening people's thinking, to me, has the feeling of a cliché.

I don't know if there is a systematic bias towards narrowness in people's thinking. There might be in specific cases. But maybe some people's thinking ought to be more focused rather than widened.

On the Mathematics of Intensity: A Logic of Self-Belonging

Thomas Duzer

"One must be a rigorous logician or grammarian, but at the same time full of fantasy and music" (Hesse)

*

"I am speaking, obviously, of philosophy and philosophers, of those who force themselves to see, to know, to prove as many things as possible in the course of their existence" (Chestov)

*

"Intense codings are connected and sometimes severe mathematics are required since, in effect, the price of victory over the shadow cast by a slumbering but perpetual captain–against the depredations of this hippocampus, then–reveals itself to be eternity and the absence of chains. Nevertheless, for the benefit, and for good reason, of those unhappy souls who remain trepidatious before it, let us recall that where self-belonging–which is substantial freedom– is concerned, where the universe is concerned, no-one is bound." (Anaximandrake)

'To be in being,' is to *be* being according to the mode corresponding to one's proper singular essence. The term 'being' is used out of convenience, for its neutrality, thus indicating no prejudice as to possible different names of being. We will see that the baptism of being is the

COLLAPSE I, ed. R. Mackay (Oxford: Urbanomic, September 2007)
ISBN 978-0-9553087-0-4

supreme activity of ontology, which for that reason cannot be ‘first philosophy’, despite the position of Aristotle and of the scholasticism that followed him. This position however differs from that of Levinas.

Necessity is the only modality of being; thus freedom is the effectuation of its own necessity. As Spinoza says, ‘freedom is not opposed to necessity but to constraint.’ This effectuation corresponds to what is commonly known as grace, or the state of grace. Each instant is the good since it can only be justified by itself. This process is in fact creation of being – that is to say, becoming. It is a question of the expression of the Mystical, of that mental zone (*qua* primary determination) that is not linguistic, but purely intensive. This expression or logic of the Mystical is called the *mathematics of intensity*. The unconscious is in fact a true physical topography (specific to each singularity) each of whose dimensions corresponds to a zone of intensity. It has *a thousand plateaus*.

The integral production of the mathematics of intensities has a preliminary requirement: the conquest of the unconscious by any means available. In fact the unconscious is first of all in chains, in a state of servitude. It is under the empire and the influence of diverse instances of the *Socius* as the power which, through the mediation of the law, separates the individual from what he can do, that is to say from his power, hence from his singular essence. These instances are grouped under the unifying aegis of the Superego which systematizes them in the form of the Ego. It is a question of the imposition of a coding filter on the singular profile of the unconscious, a filter which only allows certain passages between certain points of its territory. The rest remains in the shadows, and so we are etymologically correct to name it the unconscious. The unconscious is spoken, the unconscious speaks. *Ça parle* (*It/id speaks*). Every attack against a bastion of the coding filter manifests itself through a specific emotional phenomena: anguish. It is, moreover, by way of this sign that we can recognize that it is indeed active. Each bastion that is conquered is a step towards the annihilation of the filter. Obsession is an intermediary phenomenon; the bastion is not annihilated but besieged.

Such a parasitized, colonized unconscious (one which thus regards itself as a theatre) presents two centres of gravity. One is virtual; it is the centre of gravity corresponding to the essence of the singularity. It is virtualized by the second centre of gravity imposed in a continuous fashion by that structural effect of transcendence which is the *Socius*. This centre is called Superego if it is not identified through consciousness. In this case, the unconscious is master, the master is unconscious. Otherwise, it is known as the internal tyrant or monster (composite being) as soon as it is detected. This detection correlatively compels the localization of the singularity's own centre of gravity and the quasi-complete distinction between the Self and the non-Self. The Lacanian concept of the Other is thus dethroned in favour of a concept of negation which is internal to mathematical logic (and not to a Hegelian dialectics). This is a corollary of the destitution of the Ego in favour of the Self. At this stage, the former remains no less virtual. Its actualisation passes by way of the precise localisation of the internal tyrant or monster and the destruction of its citadel (which is not the strongest but the most strategically well-situated) permitting the metamorphosis of the Ego into the individual. The centre of gravity of the individual is the *e*go which is the informational point of compression of preceding configurations of the unconscious; it is therefore in perpetual becoming and in incessant movement in the unconscious. The ego, the unconscious and their diverse configurations form the Self.

It is a question of carefully distinguishing the *e*go, the Ego and the Self. Let us note that the speed of thought is all the faster in so far as there is no Ego, that is to say no Other, but the operator ego which generates the instantaneous synthesis of apperception and produces reflexivity as a result. Meanwhile, it is necessary that it produce a sufficient unconscious to have a memory available, that is to say in a form that is compressed and not deployed, as of a 'picture'. The ego as the engine brake. Yes, *good* narcissism, *qua* success of the mirror stage, that is to say, non-psychoanalytically, refusal of identification and thus comprehension of the reality of the illusionism of the image, is the constitution of an evolutionary story whose global coherence is suspended at the instant, open to the hard purity of the real event. The ego therefore, as necessary and variable fiction: matter and chronology and egoic form, which are separable instances, each capable of subsisting for itself. But the Self cannot be reduced to it. *Bad* narcissism proves therefore to be a belief of a transitive type: the cult of the fiction, of the *fixing*, of the Ego. Thus, the narcissistic phases must surpass the Ego, that is to say in passing by way of the intellect which is thought in act, that is to say, thought without images. In fact, the Self is not constituted on the basis of a Lacanian Other, that is, by an avatar of the dead God, but by the symbolic exchange with another rational being. It is only by way of the symbolic that experiences can be connected and integrated with each other, even whilst they remain perfectly heterogeneous in reality. Yes, first and foremost, the Self is real coherence thanks to the symbolic – contrary to the Ego which is an attempt at the imaginary conjuration of the circulating "empty case" which drives the signifiers.

Primary narcissism – that of the Ego – is mysticism of the All, that which it is not abusive to designate as the desire for fusion with the mother. The Other here is but the imaginary disguise of the Same, that is to say, the obsessive negation of every other real in an auto-parturition with no issue. The Ego is thus only a local illusion, a reflection of the absolute in a lateral pool. The Thing: stasis and abolition. It is, moreover, this rejection of the symbolic which posits the psychotic as such. *Lapsus mentis* : psychosis conflates objective genitive and subjective genitive. On the contrary, and far from the totalitarian affirmation of the Ego, the auto-referentiality conquered thanks to the symbolic instance proves to be a remedy against infinite regression. Because the only movement in which one understands *all* is that of death. The movement of nous, that which produces the opening, which constitutes the Open, when it ceases, gives way to a bounded, deployed, unfolded totality. It is indeed the mystery of All which must be clarified – in other words, that which makes a totality a totality. And it is in psychogenesis that it is appropriate to seek the solution: first alterity encountered, neoteny of the human animal. This is moreover why the language of the human being *qua* social, since language-using, logically produces the Ego. Let us note in this regard that the substantial Ego is nothing but the perturbation of the Self's relation to Self (that is to say of reflexivity), and this evidently for the purposes of subjugation. It is therefore not so much that the All is an unattainable mirage, an illusion specific to the suspension of senses. The problem is rather that the All is in fact homogeneous with a repose modeled on death, a death which is the truth of all transcendence. However, madness will never be mad enough to render the ontic and the ontological indistinct. Transcendence *versus* chaos? No. Let us be clear: the wisdom adequate to chaos, that is to say to a truly inhuman madness, is discernment.

We should in fact realize that the point of being proves to be junction of the real, the imaginary and the symbolic. No precedence of any one of these dimensions over any other. Otherwise, transcendence *qua* asymmetric cut arrives as a hallucination provoking real effects. This caesura, heterogeneous to the symbolic, is the arrival of the void as such, that is to say, of non-being as phantasm. Because it is indeed castration which is the origin of the imaginary's real takeover of power. In effect, the sovereign image is the negation of the *puncta coacta* which constitute it, and thus the affirmation, by denial, of the All. Denial of castration? In fact, it is the delirium of the All itself which testifies to castration. The real of castration is delirium, not as process but as legitimation of the takeover of power of one of the dimensions of being. Yes, the symbolic caesura differs from castration because it is the condition of connection and disconnection, that is, of the formation of alls. In fact, there is no all which is not fragmentary, and thus relative. An all is not all unless there exist possible components which it does not totalise. Yes, the pure multiple is untotalisable. Were this not so, the absolute, formalised, would annul itself infinitely. This is in fact the mistake of all religion: faith as strict inverse of doubt, correlate of the exclusion of their subsumption.

In short: the All is the index of transcendence, that is of coalescence between the real and the imaginary, thus of the refusal of the symbolic, that is to say of the other, and thus, as we will see, of the Self. Differences, feared, are aligned under the category of opposition. It is remarkable that it is the rejection of the other that gives birth to the Other, that is to say to the very possibility of alienation. One sees then that it is a sophistic tropism that makes possible voluntary servitude, then denied, hence perfectly interiorised. But no, all is not in language, and the "All" is only in language. Yes, since it reflects nothing, being appears as chaotic, void, or eternal multiplicity disseminating itself sempiternally. Thus, presence *qua* eternal is the assumption of time as event of pure difference, this paradoxical substance. But to attain the All – the end of time – in excluding the other, that is to say the Self, amounts to joining with the Other – that is to say, with nothing.

But, let us be specific. We have said, necessity is that of the singular essence, that is to say real essence. There is no global necessity unless there is a One-All, therefore an outside of the universe, that is to say if 1=2. This initial paradox tries to conjure up freedom, the unpredictability of the living, and notably as to the issue of the struggle until death. For a judgment, second illusion, which is triplopia, it would have to be that 1=3. In this case, the delirium goes even further. Desire in an impasse, construction of sin *ad hoc,* the big Other. *Ne uter*. In achieving the paternity of the One, one would lose in it the immanent distinction in the indiscernible, this mixture escaping the dialectic of the void and the plenum. This is to say that one would lose the act of the intellect, the movement of *nous*. One would thereby lose singular individuation in favour of a regular cloning. And we can be sure that this would indeed be a shame, so long, of course, as one allows this anti-wager, which is an authentic risk, hence one which no law probabilises in advance.

Thus one and one only entity or instance, the Self, is "conscious" of "its" contents via the intermediary of *reflection* between individuals. The obstacle, which is considerable, is that one finds some who take themselves for Egos. But the Ego is a false unity, a false coherence which, in order to subsist qua illusion, must mortgage the future in the form of a quasi-cancerous growth, by destroying – that is, consuming – possibles. It is in fact its internal contradiction which forces it to submit in order to be able to project its contradiction, and make of the other the imaginary suffering appendix of its fictive Ego. But to make an Ego, you need at least two bodies. Even the dialectic of master and slave, that servile caricature, requires two human beings, for it deals with desires and consciousnesses. Not that of the Ego. In fact, it is a question there only of a relation between an object and its possessor. This is patently obvious, for example, in fetishism. Recall Federer's thesis, reprised by Bergler (the typical neurotic): the slave dedicates himself to the master in order to escape the panic to which his freedom exposes him. But by the same token, this master is only his instrument. *Ellipse.*

Consequently – and this is no solipsism – there is a Self, diversely modified into spirits and bodies which are images, that is to say, figures of the agency of the imaginary. The Self *qua* intensive is nevertheless traversed by the symbolic dimension of language, that is to say, perceived as an Other which affects the Ego. Nevertheless the Self is one and "unreflectable". One cannot "see" it, since it is not an Ego, an image, but, on the contrary, that place from which one sees. Here we are far from the form of the Ego. The Self is that "planomenon" (Deleuze), that paradoxical substance where the polyphony of intensities circulates in pure immanence; intensive grammar itself in perpetual differance since it is connection, syntax of differences. "To be in being": here one is indeed involved in a logic of self-belonging.

But to believe in the Ego or in the Unique (Stirner) is much more than not to believe in anything, it is to believe in nothing. And as Weininger says: "cowardice is a way of taking nothingness to be something". For their part, in fact, the nihilists preach, whether silently or not, and along with others, the following: do not expect anything. But this is to expect nothing. In fact, the nihilist always expects something but it is nothing that he desires. Even alerted by Blanchot that the apocalypse disappoints, he waits, and that is *all*. He does not want himself living, for that would be to risk, enjoyment certainly, but above all suffering: he wants himself dead. Now, this nothing would not be lack unless there was the possibility of something in its place. Certainly, certain halfwits, subtle rhetoricians that they are, will not hesitate to object that lack is precisely something. Which is true, indubitably so. Isn't it in this way that we can understand the demon of the malicious Descartes' *Cogito*? But let us reassert that "nothingness has no properties"; and refuse every "effect", every mystification, as base. For you will only find the plenum there where it is not lacking, which is to say, there where it is. It could only be lacking where it is not if it were there. Which is to say that it is logically contradictory for it to be lacking. In effect, it is not lacking in its place because the place does not belong to it. Certainly, there is void where one looks for the plenum. But the question is: in whose interest is it to put your desire, which lacks nothing, in an impasse? Who could want to set up contradiction at the very fundament of ontology? Those who satisfy their desire through your impotence, those who rule by and on the basis of anguish. Because, and this is the only axiom of their "science", they know full well that anguish is the link to lack. Here, the secret of tyrannies reveals itself, all the more blinding for it. Being is no longer the knot of the real, symbolic, and imaginary, but that which is put in quotation marks becomes *lèse-majesté*, and being is nothing more than that which passes via the mouth. Because, just as the Stoics knew – and this is only a paradox for the excarnated of all descriptions – it is the incorporeal which renders possible the real mixture of bodies. It is the very condition of possibility for the event. Yes, despite the egoic myriads, the symbolic is transcendental.

It is therefore clear that to recognise the instance of the Other is, paradoxically, to misrecognise that of the symbolic. To posit the Other is to render castration unsurpassable, transcendent. But the instance of the Other is only a projection of the imaginary upon the symbolic. This is indeed what leads us to claim that the Ego only arises from the SuperEgo (*qua* effect of a certain type of *Socius*). Certainly, "something", in the symbolic, must structure the Id; but the SuperEgo petrifies it, *i.e.*, produces the Ego. Another organisation of the Socius is therefore necessary to resolve this problem. In fact, castration, linked to the imaginary belief in the Other (the uncastratable), induces the separation between the zones of highest intensity.

Nihilism is therefore, as Nietzsche emphasised, the touchstone. Its partisan is on the near side of the intuition of the distinction between joy and sadness, between augmentation and diminution of desiring-power. "What sense? What sense?" chants this ridiculous parishioner, a sort of plebeian relativist Heraclitus, for whom ascent and descent are equivalent. So, that place "where we feel the whole nervous system burning like an incandescent lamp" (Artaud) is for the nihilist a place unknown, or perhaps forgotten – but, at least, lost. It is true, as Gabriel Marcel says, that this type of philosophy, which, fundamentally, opposes to being an end not to receive, is coherent, rational, "philosophical" in sum. Likewise, Sartre concedes that the spirit can deny itself and even possesses an infinite power of doing so. And already, the cavalier Descartes, that Pascal from before the Fall, finds the reason for that strange mania in the disproportion between finite understanding and infinite will. Point noted.

Thus, whether it is a case of the All, of God or of the Ego, every philosophy of the transcendent One is indeed in this sense a nihilistic and ancillary philosophy. Yes, in order to be able to reciprocate (whether explicitly or not) being to the One, it cannot but differentiate them, but as derived. But let us posit a precondition: Spinoza, according to the *vulgate*, is a philosopher of the One-All. We will nevertheless retort that his system leans towards Epicurism and Atomism. Because it is indeed rather Neo-Platonism which is the philosophy of the One-All; it is the doctrine of emanation which properly characterises the latter. Good and Evil are its autophagous principles: the absolute devours itself in it. Psychosis and transcendence. In complete contrast, Spinozism is pure immanence. The good and the bad are only ever said relatively here, but are nevertheless absolutely distinct. Here is the difference: joy has no need of sadness. Joy as augmentation of power is sufficient unto itself, whilst sadness is servile, bound to lack, that is to say, to anguish. Thus, it is with absolute sovereignty that Spinoza withdraws God from the grip of the theologians and their creed, and makes of it the pure multiple which is only multiple of itself. His work, and in particular the polemical *scolia* of the *Ethics*, demonstrates this clearly.

Not cannibalistic bipolarity, but one axis only: aristocratic joy as augmentation of force. Chronos emasculated. What is power [*pouvoir*], then? It is merely the lowest degree of force [*puissance*]; it is force's separation from itself, self-separation and projection of this separation. Thus: the One is pure alienation. Hence it is the instance which allows the others to link themselves into a whole. Thus there are ones. Which can also be said: there is only one and the other if One occupies the function of the Other, that is to say the One *qua* alienated. Now, this function of the Other, if it is a question of joy, becomes that of negation. No dialectic. Negation of negation does not yield identity. It is identity which denies itself in denying. Being is not becoming, it is becoming which creates being. What of their conflation? It is the Ego. The non-Self is the site of transcendence alienated in perpetual negation but, therefore, and consequently, of itself, that is to say of its Self which is illusion and its sole substance. For the One is indeed a pure generic difference, but the latter is without relation, and consequently, without Self. Self-sufficient image. But the image, irremediably, is punctured. It is thus the epiphany of the perverse process in the pure state: the image identified with being, the terrible synecdoche. Non-separation, devourment, death fantasmatically denied, swallowed. Immortality is promised to the perverse only in exchange for their absolute alienation. But who makes it necessary? For in fact joy is entirely other, eternity, *hic et nunc*, that is to say the pure Self which arises from the relation of pure differences. Yes, the Self is the indiscernability of the one and the multiple.

Thus the mathematics of intensities is firstly a geography, a cartographical relief map of the unconscious. But secondly, it proves to be a pure pragmatics. In fact, thanks to nous, to the intellect, an automatic computation is effectuated which mobilises, in the Self, the full gamut of intensities, and extracts those which are adequate to the solicitations of the non-Self, whether it is a matter of connections or disconnections, that is to say of compositions or of decompositions of relations, of links. Thus the domain of "us" can arise. From now on, the unconscious is productive, that is, capable of continuous creation. At this stage, it is possible, by way of a *linguisterie*, to replace the term 'unconscious' by the term 'in-conscious'. In fact, the liberated unconscious is not conscious in the sense of being re-presented reflexively in consciousness but in the sense of being intensively presented in *it*. Then, and only then, is it a question, for the philosophies of the multiple and of the concept, of effectuating logical conjunctions (connections and disconnections), that is to say, within the immanence thereby conquered, of creating significant liaisons in systems of relations which are external to their terms. This is how the mathematics of intensities, which is the logic of self-belonging, and hence etho-onto-logic, can become a real pragmatics, that is to say, a constructivist philosophy between free individuals.

Various tactical and strategic mappings, scattered and principally offensive, disseminated in universal literature, await an Esperanto. The science of these lacings and interlacings has yet to be elaborated. This mathematics of intensities is the real ethics of the event, the practical science of manners of being, that is to say, an empiricism at once superior (Schelling) and radical (William James), and therefore transcendental (Deleuze). It is the knowledge of desire since "desire is the very essence of man" (Spinoza). If we connect this theorem with another Spinozist theorem, namely "essence is force", we immediately deduce that the force of man is desire. Being being produced by becoming, ontology, the science of being *qua* being, is logically secondary. In this way, etho-onto-logic becomes capable of supplanting the ancient onto-theo-logy, since the coherence (of Logos in act, the actualisation of Logos), which differs from the non-contradiction of classical logic, is no longer that of the Ego or of God but that of the force of desire. Heraclitus, the Stoics, Montaigne, Spinoza, Hume, Nietzsche, William James and Deleuze (and perhaps even Wittgenstein) were already closer to etho-onto-logy. But they conceptualised an onto-etho-logy without naming it as such. To name it thus proves that each of them actually taught the inverted double of that which they did, that is to say, an etho-onto-logic in act. They were individuals but designated individuality without conceptualising it. This is why Spinoza's *Ethics* is written invertedly (incessant shuttling, halls of mirrors, figures of light): substance turns around the modes and not the other way around. So it is that the name of being is that which, *logically*, gives it becoming in immanence. *Igitur.*

Qabbala 101

Nick Land

INTRODUCTION

Is qabbalism problematical or mysterious? It seems to participate amphibiously in both domains, proceeding according to rigorously constructible procedures – as attested by the affinity with technicization – yet intrinsically related to an Outsideness through which alone it could derive programmatic sense.

If there is no source of at least partially coherent signal that is radically alien to the entire economy of conventional human interchange, then qabbalism is nothing but a frivolous entertainment or a fundamentally futile practical error. Yet unlike any kind of metaphysical assault on 'the noumenal', qabbalism cannot be definitively critiqued on a purely rational or formal basis, as if its mode

COLLAPSE I, ed. R. Mackay (Oxford: Urbanomic, September 2007)
ISBN 978-0-9553087-0-4
http://www.urbanomic.com

of 'error' was that of logical fallacy. Since qabbalism is a practical programme, rather than a doctrine of any kind, its formal errors – mistakes – are mere calculative irregularities, and correcting these is actually a procedural requirement of (rather than an objection to) its continued development.

It is the rational dismissal of 'the' qabbalistic enterprise that is forced to take a metaphysical stance: ruling out on grounds of supposed principle what is in fact no more than a guiding 'empirical' hypothesis (that signal from 'outside the system' is detectable by numerical analysis of codes circulating within the system).

Epistemologically speaking, qabbalistic programmes have a status strictly equivalent to that of experimental particle physics, or other natural-scientific research programmes, even if their guiding hypotheses might seem decidedly less plausible than those dominant within mainstream scientific institutions.

Lovecraft understood the epistemological affinity between natural science and programmatic (as opposed to doctrinal) occultism, since both venture into regions once declared mysterious, following procedures of a rigorously calculative-problematical type. It is the alliance between purely speculative metaphysics and common sense that betrays such affairs of pure reason to futility, since they lack the calculative traction to revise their own conventional notions on the basis of their encounters. Practices – however implausible their guiding motivations – can know nothing of absolute mystery or metaphysical transcendence because their realm of certainty is procedural-problematic and uncontroversial, whereas their reserve of knowledge is empirical, refutable, repeatable, revisable, nonmystical and accumulable.

There may be no 'empirical', procedurally approachable mysteries – or mysterious problems – of the kind qabbalism guides itself towards. If so, it will approach this fact in its own way – empirically, probabilistically, impressionistically, without any logical, transcendental or philosophical meta-discourse ever having been positioned to put it in its place.

I. POPULAR NUMERICS

Traditional gematria (whether Hebrew, Greek, Farsi or Arabic[1]) have distinctive typical features: (1) They substitute letters for numerical values, overcoding numerals where they exist. (2) They code for discontinuous numerical values, typically 1-10, then 20, 30 ... chunked in decimally significant magnitudes.

The ocean in which qabbalism swims is not mathematics, but popular numerical culture. From a mathematical perspective it remains undeveloped, even ineducable, since it cannot advance beyond the Natural number line even to the level of the Rationals, let alone to the 'higher' numbers or set-theoretical post-numerical spaces. Where counting ceases, qabbalism becomes impracticable.

---

[1] See Incognitum, 'Introduction to ABJAD', in the present volume.

Socially, qabbala makes an implicit decision against specialization, in order to remain virtually coincidental with the entire economy of digitizable signs. It is essentially 'democratic' (in the most inclusive sense of this word), even when apparently lost in its own trappings of hermeticism. It is bound to the 'blind' undirected contingencies of pre-reflective mass-social phenomena, with all the inarticulate provocation this entails in respect to professional intellectuals. Wherever exact semiotic exchange occurs, a latent qabbalism lurks (even within the enclaves of intellectual professionalism themselves). Deleuze & Guattari's 'Nomad War Machine', within which number is socially subjectivized, captures crucial aspects of this qabbalistic fatality.

Historically, qabbala arises through epic accident, as a side-product of the transition between distinct modes of decimal notation. Its historical presupposition is the shift from alphabetical numerals (of the Hebrew or Greek type) to modular notation, with its resulting unlocalizable (and theoretically indeterminable) confusion. This transition provided the opportunity for a systematic calculative 'error' – the mistaken application of elementary techniques appropriate to alphabetical numerals – simple addition of notated values – to the new modular signs. This mistake automatically resulted in digital reduction, by accident, and thus as a (theoretically scandalous) gift of fate. Arising historically during the European Renaissance - when zero, place value and technocapitalism finally breached the ramparts of Western monotheism – qabbalism (born in a semiotic glitch and thus lacking the authority of tradition or even purpose) was compelled to hyperstitionally generate an extreme antiquity for itself, in a process that is still ongoing.

Technically, qabbala is inextricable from digital processing. Emerging from calculative practicality within the context of blind mass-cultural metamorphosis, it antedates it own theoretical legitimation, making sense of itself only derivatively, sporadically and contentiously. Its situation is analogous – and perhaps more than analogous – to that of a spontaneous artificial intelligence, achieving partial lucidity only as a consequence of tidal pragmatic trends that ensure an integral default of self-mastery. Practical systematization of technique precedes any conceivable theoretical motivation. Dialectical interrogation of qabbalism at the level of explicit motivation thus proves superficial and inconsequential, essentially misrecognizing the nature of the beast. (It is equally misleading to ask: What is a computer really for?)

Politically, qabbalism repels ideology. As a self-regenerating mass-cultural glitch, it mimics the senseless exuberance of virus, profoundly indifferent to all partisan considerations. Indifferent even to the corroded solemnity of nihilism, it sustains no deliberated agendas. It stubbornly adheres to a single absurd criterion, its intrinsic 'condition of existence' – continual unconscious promotion of numerical decimalism. Qabbala destines each and every ‘strategic appropriation’ to self-parody and derision, beginning with the agenda of theocratic restoration that attended its (ludicrously robed) baptismal rites. Even God was unable to make sense of it. It has no party, only popularity.

II. PRIMITIVE NUMERIZATION

Among the primary test-beds for qabbalistic analysis are the numerolexic systems inherited from cultures overcoded by the modern Oecumenic alphabet. These include the Hebrew and Greek alphabets (with their Neoroman letter names and mathematico-notational functions) and the Roman numbers (inherited as Neoroman letters and still numerically active in various domains). In this respect, the absence of names for Neoroman letters are an index of their pseudo-transcendence – as ‘unnameable’ – within the present Oecumenic order.

A discontinuity is marked in the alphanumeric series (0–Z) by the fact that the numerals composing the first ten figures in this series do have names, grouping them with the letters of previous alphabetical numbering systems from a certain qabbalistic perspective. This might be taken as the residual indication of an ‘alien quality’ still characterizing the numerals in relation to the Oecumenic cultural order they now indisputably occupy, a legacy of the cultural trauma attending their introduction.

The qabbalistic provocation posed by the English number names is conceptually comparable to that of any other numerolexic system, while surpassing any other in the intimacy of its challenge. If the numerals have names, shouldn't the qabbalistic processing of them as words yield – at the least – compelling suggestions of nonrandom signal? If the standard numeral names emit nothing but noise when qabbalistically transcoded, the attempt to establish relatively persuasive criteria for the evaluation of qabbalistic results suffers an obvious and immense reverse.

What, then, would count as a minimally controversial first step in such an examination?

Surely the most basic of all qabbalistic (or subqabbalistic?) procedures is simple letter counting – Primitive Numerization (PN). As a reversion to sheer 'tallying' PN has a resonance with the most archaic traces of numerical practice, such as simple strokes carved into mammoth bones and suchlike palaeo-ethnographic materials. If anyone was to bother systematizing PN procedure for the purpose of mechanization or simply for conceptual larity, it would be most efficiently done by transcoding ('ciphering') each letter or notational element as '1' and then processing the result numerically.

PN's extremely tenuous relation to issues of modulus-notation ensures that it can only ever be a highly dubious tool when intricate qabbalistic calculation is required. Yet this utter crudity also makes it invaluable as a test case, since it minimizes axiomatic arbitrariness and precludes any plausible possibility of symbolic conjuration ('sleight of hand') while fully sharing the qabbalistic 'deficiency' of sufficient anthroposocial or communicative motivation. Common reason – sanity – insists upon noise as the only PN output consistent with the general intelligibility of signs (a pre-judgement applying rigorously to all qabbalistic procedures).

No message should inhere in the length of a word, excepting only the broad pragmatic trend to the shortening of commonly used terms. It is immediately obvious why this exception has no pertinence to the case in question here, unless stretched to a point (for instance, expecting the smaller numerals to exhibit the greatest lexical attrition) where it is straightforwardly contradicted by the actuality of the phenomenon.

So, proceeding to the 'analysis' – PN of the English numeral names: ZERO=4, ONE=3, TWO=3, THREE=5, FOUR=4, FIVE=4, SIX=3, SEVEN=5, EIGHT=5, NINE=4. Is there a pattern here? Several levels of apparent noise, noise, and pseudo-pattern can be expected to entangle themselves in this result, depending on the subsequent analytical procedures employed.

To restrict this discussion to the most evident secondary result, not only is there a demonstrable pattern, but this pattern complies with the single defining feature of the Numogram[2] – the five Syzygies emerging from 9-sum twinning of the decimal numerals[3]: 5:4, 6:3, 7:2, 8:1, 9:0.

---

[2] . On the Numogram, see *Abstract Culture 5:Hyperstition* (1999).

In the shape most likely to impress common reason (entirely independent of numogrammatic commitments) this demonstration takes the form: ZERO + NINE = ONE + EIGHT = TWO + SEVEN = THREE + SIX = FOUR + FIVE – revealing perfect numerolexic-arithmetical, PN-'qabbalistic' consistency.

The approximate probability of this pattern emerging 'by chance' is 1/243, if it is assumed that each decimal digit (0-9) is equiprobably allotted an English name of three, four, or five letter length, with 8-sum zygosys as the principle of synthesis. 7-sum or 9-sum zygosys are inconsistent with any five or three letter number-names respectively, and thus complicate probabilistic analysis beyond the scope of this demonstration (although if everything is conceded to the most elaborate conceivable objections of common reason, the probability of this phenomenon representing an accident of noise remains comfortably below 1/100).

Partisans of common reason can take some comfort from the octozygonic disturbance of the (novazygonic) Numogrammatic reference. How did nine become eight (or vice versa)? Lemurophiliac numogrammaticists are likely to counter such queries with elementary qabbala (since digital cumulation and reduction bridges the

---

[3] . PN confirmation of the Numogrammatic Novazygons (9-Twins).
ONE + EIGHT = NINE + ZERO. (PN 3 + 5 = (4 + 4 =) 8)
TWO + SEVEN = NINE + ZERO. (PN 3 + 5 = (4 + 4 =) 8)
THREE + SIX = NINE + ZERO. (PN 5 + 3 = (4 + 4 =) 8)
FOUR + FIVE = NINE + ZERO. (PN 4 + 4 = (4 + 4 =) 8)

'lesser abyss' in two steps, 8 = 36 = 9, as diagrammed by the 8th Gate connecting Zn-8 to Zn-9).

III. AGAINST NUMEROLOGY

Consider first an extraordinarily direct numerological manifesto:

> When the qualitative aspects are included in our conception of numbers, they become more than simple quantities 1, 2, 3, 4; they acquire an archetypal character as Unity, Opposition, Conjunction, Completion. They are then analogous to more familiar [Jungian] archetypes...

It is hard to imagine a more 'archetypal' expression of numerological ambition than this. Yet rather than meeting this claim with docile compliance, the qabbalist is compelled to raise a number of awkward questions:

(1) How can a numerological coding that proceeds in this fashion avoid entrapping itself among the very smallest of Naturals at the toe-damping edge of the number line? If '4' symbolizes the archetype 'Completion,' what to make of 127, 709, 1023, or similar small Naturals? Do they also have analogues among the intelligible archetypes? How would one 'qualitize' ($2^{127)}$-1, or a larger number (of which there are a very considerable number)?

(2) Is an 'archetype' more basic than a number in its unsymbolized state? Does 'qualitizing' a number reveal a more elementary truth, a germ the number itself

conceals, or does it merely re-package the number for convenient anthropomorphic consumption, gift-wrapping the intolerable inhumanity of alogical numerical difference and connectivity?

(3) Why should a number be considered 'quantitative' in its Natural state? Is it not that the imposition of a quantity/quality categorization upon the number requires a logical or philosophical overcoding, a projection of intelligibility alien to the number itself? Quantity is the decadence of number (while quality is its perversion), so – since arithmetic provides no basis for a reduction of the numerical to the quantitative – what is the supposed source of this (numeric-quantitative) identification (other than a disabling preliminary innumeracy)?

(4) If '1' numerologically evokes 'Unity,' why should UNITY not qabbalistically 'evoke' 134 (=8, its Numogrammatic twin[4]) with equal pertinence? Can any expressible 'archetype' avoid re-dissolution into the unfamiliarity of raw number pattern? Numerology might assimilate '2' to opposition, but OPPOSITION = 238 = 13 = 4 (twice 2, and the Numogrammatic twin of ('4' = COMPLETION = 212 =) 5), while even if numerological '3' as CONJUNCTION = 237 = 12 = 3 finds itself qabbalisitically confirmed (at the extremity of its decimaliza-

---

[4] . Employing August Barrow's 'Anglossic Qabbala', the basic tool of which is the Alphanumeric Gematria. This numerization of the Neo-Roman alphabet , continuing the procedure now familiar from Hexadecimal, is a continuous nonredundant system, supplementing the numerals 0-9 with numerized letters from A (=10) to Z (=35), treating the 0-Z alphanumeric sequence as a numeral succession, corresponding to the numerals of a modulus 36 notation.
Thus UNITY = 30+23+18+29+34 = 134. 1+3+4 = 8.

tion), this is not, perhaps, in an altogether comfortable mode.

Numerology may be fascinated by numbers, but its basic orientation is profoundly antinumerical. It seeks essentially to redeem number, through symbolic absolution into a 'higher' significance. As if the concept of 'opposition' represented an elevation above the ('mere') number two, rather than a restriction, subjectivization, logicization and generalized perversion, directed to anthropomorphic use-value and psychological satisfaction. Archetypes are sad limitations of the species, while numbers are an eternal hypercosmic delight.

Nevertheless, qabbalism is right up against numerology, insofar as it arises 'here,' within a specific biological and logocratic environment. The errors of numerology are only the common failures of logic and philosophy, human vanities, crudified in the interest of mass dissemination, but essentially uncorrupted. The numeric-critique (or transcendental arithmetic) of a Gödel (or Turing, or Chaitin (or Badiou?(??(???)))) can be rigorously transferred to this controversy, demonstrating – within each particular milieu – that overcodings of numerical relation by intelligible forms – 'archetypes' or 'logics' – are unsustainable reductions, reefed on the unsurpassable semiotic potency of number. Gödel has shown that there is always a number, in fact an infinitude of (natural) numbers, that simulate, parody, logically dialectize, paradoxically dismantle, archetypally hypervert, and in whatever way necessary subvert each and every overcoding of arithmetic. Number cannot be superseded. There is no possibility of an authoritative 'philosophy of arithmetic' or numerological gnosis.

Qabbala assumes that semiotics is 'always already' cryptography, that the cryptographic sphere is undelimitable. It proceeds on the assumption that there cannot be an original (unproblematic) coding, providing the basis for any solid definition or archetypal symbol, since the terms required for such a coding are incapable of attaining the pure 'arbitrariness' that would ensure the absence of prior cryptographic investment. There is not – and can never be – any 'plain text,' except as a naïve political assumption about (the relative (non)insidiousness of) coding agencies and the presupposition that communicative signs accessibly exist that are not already 'in code.' Since everything is coded, or (at least) potentially coded, nothing is (definitively) symbolic. Qabbalistic cryptocultures – even those yet to come – ensure that number cannot be discussed or situated without subliminal or (more typically) wholly unconscious participation in numerical practices. Logos, including that of numerology, is also always something other than itself, and in fact very many things.

Qabbalism thus operates as an inverse or complementary Gödelian double-coding. Where Gödel demonstrated that the number line is infested by virtual discursive systems of undelimitable topicality and complexity, pre-emptively dismantling the prospects of any conceivable supranumerical metadiscourse, qabbala demonstrates that discourses are themselves intrinsically redoubled (and further multiplied) by coincidental numerical systems which enter into patterns of connectivity entirely independent of logical regimentation.

The supposed numerical de-activation of the alphabet, marking semiotic modernity (the era of specialized numerical signs), has an extremely fragile foundation, relying as it does upon the discontinuation of specific cultural procedures (precisely those that withdraw into 'occultism') rather than essential characteristics of signs themselves. The persistent numerical functionalization of the modern alphabet – with sorting procedures based on alphabetical ordering as the most prominent example – provides incontestible evidence (if any was required) that the semiotic substructure of all Oecumenic communications remains stubbornly amphibious between logos and nomos, perpetually agitated by numerical temptations and uncircumscribed polyprocesses.

At the discursive level, any 'rigorization of qabbala' can only be a floating city, with each and every definition, argument and manifesto continually calving off into unmasterable numerical currents and alogical resonances. How could qabbala be counterposed to a code, to meaning and reason, when CODE (= 63) finds duplicitous harmonics in MEANING = REASON = 126? If qabbala positions itself discursively AGAINST NUMEROLOGY (= 369), the echoes of its novanomic signature perpetuate themselves even through such unlikely terms as

SIGNIFICANCE (= 207) and SIGNIFICATION (= 252). Pronouncements that begin as projected logical discriminations revert to variations on triplicity and the number nine, performing a base qabbalistic subversion of philosophical legislation and its authority to define (or delimit connectivity).

No polemic against numerology – whether conducted in the name of qabbala or of Oecumenic common reason – will transcend the magmic qabbalistic flux that multiplies and mutates its sense. Perhaps dreams of numerological archetypes even sharpen the lust for semiotic invention, opening new avenues for qabbalistic incursion. But this at least is certain: Numbers do not require – and will never find – any kind of logical redemption. They are an eternal hypercosmic delight.

Editorial Introduction

Robin Mackay

This volume comprises a selection of texts, some of which would not have existed, others of which may not have been published, and none of which would have ended up in such odd company, were it not for the underlying vision of **COLLAPSE**, which seeks to generate and to bring together philosophical writing from varying perspectives with work drawn from other fields, in order to challenge institutional and disciplinary orthodoxies and to set in motion new syntheses. This second volume has emerged, as did its predecessor, from the combination of this overall vision, a collaborative process with the authors, and a set of happy coincidences. The result is, we hope you will agree, a rich and rewarding set of conceptual conjunctions.

The first part of the volume coalesced into a 'dossier' centring on the work of QUENTIN MEILLASSOUX, whose

COLLAPSE II, ed. R. Mackay (Oxford: Urbanomic, March 2007)
ISBN 978-0-9553087-1-2
http://www.urbanomic.com

recent book *After Finitude*[1] is a work designed to fundamentally disrupt that dubious consensus within continental philosophy which emphasises the primacy of the relation of consciousness to the world – however that may be construed – over any supposed objectivity of 'things themselves'. It may seem that, in the wake of Kant's Copernican Revolution, this 'correlationist' credo – the injunction that, unable to know things 'in themselves', philosophy must limit itself to the adumbration of 'conditions of experience' – is unassailable, something that only the most unsophisticated, 'pre-critical' thinker would seek to challenge. And yet, once this consensus is broken, the consequences are startling.

In 'The Enigma of Realism' RAY BRASSIER gives a lucid exposition of this transvaluation of the stakes of contemporary philosophical thought. However, questioning whether Meillassoux is right to single out the 'arche-fossil' as the privileged site of this contestation, Brassier ultimately suggests that the curse of correlationism runs deeper still, and intimates that an even more thoroughgoing 'decontamination' of the tools used to critique the current *doxa* might yet be necessary. Brassier's text already takes us beyond the scope of Meillassoux's book, identifying a number of serious problems which he identifies as issuing from a 'fundamental dilemma' relating to Meillassoux's proposal to reinstate some form of intellectual or mathematical intuition. Brassier's text almost tends toward a dialogic form, as Meillassoux responds to subsequent objections with further refinements of his own position.

---

[1] *Après la Finitude: Essai sur la necessité de la contingence* (Paris: Seuil, 2006). English translation *After Finitude* (trans. R. Brassier) (London: Continuum, forthcoming 2008).

Meillassoux's audacious countermanding of philosophy's historical abjuration of speculative rationalism proceeds via the positing of the 'necessity of contingency' indexed to an absolute time. In 'Potentiality and Virtuality' he sketches a route to this principle via a discussion of Hume's problem of causality. With admirable panache, Meillassoux rescues this perennially abandoned problem from its alleged epistemological dissolution and restores it to its most potent ontological form. This is a question of resisting the pragmatist referral of ontological problematics to heuristic solutions rooted in empirical consensus: the apparent necessity of a recourse to an empirical *genesis* of the law rather than a metaphysical *grounding* for it, Meillassoux suggests, results from supplementing the terms of the problem with a 'common-sense' judgement that is in turn rooted in an inappropriate application of probabilistic thinking. Conversely, a philosophical enterprise with the courage of its conviction in rationality would refuse to concede this 'defeat of reason', daring to affirm on the contrary that there is in fact no reason to postulate the constancy of natural laws.

Thus Meillassoux sketches the contours of a bold reclamation of rationalism issuing from the refusal of particular forms of (probabilistic) reasoning embedded in 'common-sense'. Rather than seeking a 'meta-law' to subtend the laws of reality, Meillassoux instead loosely binds reality within the singular rational principle of an 'absolute contingency'.

It is perhaps owing in part to his relative independence from the philosophical issues at stake here that our interview with theoretical cosmologist ROBERTO TROTTA serves in many ways as the centrepiece of this discussion. Following as it does upon the more abstractly philosophical discussions of the previous two papers, and yet circling around essentially the same issues, this interview serves to lend instructive insight into the transformation which ostensibly purely *a priori* philosophical problems undergo when transposed into the concrete contexts of scientific research programmes. It would be impossible here to provide more than the barest sense of the content of this lengthy conversation, which we feel sure will repay repeated reading. Fully confirming our faith in the potential of the interview as a (sadly under-exploited) form of contemporary intellectual engagement, this conversation provides an invaluable perspective upon the problems surrounding the determination of 'ancestral phenomena' (Meillassoux's 'arche-fossil') from the privileged 'insider' vantage-point of someone immersed in their empirical study and scientific interpretation on a daily basis. Touching as it does upon everything from the evidence for and ontological status of 'dark matter' through string theory, anthropic reasoning, inflationary cosmology and the meaning of concepts of time and space in cosmological contexts, this interview not only lends a much-needed sense of concreteness and specificity to the problems introduced by Brassier and Meillassoux, but also provides a helpful and readable introduction to the most up-to-date problems and findings of contemporary cosmology.

If Meillassoux's neo-rationalism draws upon the resources of transfinite mathematics and set-theory in order to precisely locate the fundamental parameters of rational thought itself, GRAHAM HARMAN's contribution aims at a different kind of precision, one which perhaps has more affinity with Bergson's critique of dialectical concepts as being 'too large', 'not tailored to the measurements of the reality in which we live'[2] – 'baggy clothes'[3] which, covering everything, reveal little and stifle movement. If Harman, no less than Meillassoux, seeks to escape the prevailing *doxa* which would see in the relation between consciousness and world the primary hinge of any philosophy worthy of the name, and if both thinkers are equally intent on resuscitating a 'speculative realism' long-since left for dead by the philosophical mainstream, it would yet be difficult to find two more starkly contrasting styles of philosophizing.

Harman's inquiry bears no less than Meillassoux's upon the problem of 'correlationism', however. Against Meillassoux's positive desertion of a philosophical demonstration of causality, in 'On Vicarious Causation' Harman seeks to revive the problem of causation itself in all its specificity, beyond the question of whether it can be known or justified, and claims that the revival of this problem entails the rejection of Kant's Copernican turn 'and its single lonely rift between people and everything else'. Whereas for Meillassoux the problem is the apparent facticity of the 'correlationist gap', Harman sets out to generalise this gap, shattering the cosmos into absolutely disjunct objects. Through his generalisation of Heidegger's famous tool-analysis in *Being and Time*, Harman attempts to maintain a recognisably phenomenological commitment to the ontological anteriority of the ‘manifest’ over the ‘scientific’ image of the world whilst simultaneously acknowledging the chronic futility of anti-scientific philosophies of presence. If here philosophy engages ‘the same world as the various sciences’ but ‘in a different manner’, it is not through a meditation on the presencing and absencing of Being, but rather through a tracking of the ‘grain’ of the immediate phenomenon in which a new ‘first philosophy’ is announced in the guise of an aesthetics.

---

[2] H. Bergson *Oeuvres* (*La Pensée et le Mouvant*) (Paris: PUF, 1963), 1/1254.

[3] G. Deleuze *Bergsonism*, trans. H. Tomlinson & B. Habberjam (New York: Zone Books, 1991), 44.

In blazing this trail Harman introduces a refreshingly novel philosophical language which is still a work in progress. It is already, however, a work that finally goes beyond those interminable mantras preparatory to phenomenology in which the Heideggerian corps has by now been drilled for decades. Harman sets out, with a hard-won philosophical innocence, to *do* phenomenology in an entirely new way, a way which conjoins the immediacy of the phenomenon with the affirmation of the reality of the object. The future of this enterprise deserves to be followed closely.

Neurophilosopher PAUL CHURCHLAND has no qualms about cleaving to the scientific image, and in our informal and wide-ranging interview makes it entirely clear that, at least in his own area of research, the sense of unfamiliarity that gives rise to its traditional description as ‘cold and machinelike’ (Harman’s ‘grey matrix’) should not be yielded to. Part of what is most intriguing in Churchland's take on the theme of common-sense and science is that, rather than seeing the two in a relation of dramatic rupture, he proposes that as the work of science continues, the corpus of folk-theory will gradually absorb its *prima facie* paradoxical statements.

Much of our discussion with Churchland relates to the problem of so-called ‘qualia’ – the supposedly irreducible subjective components of experience which have been for many years a touchstone for the relation between philosophy and science – and it is instructive to observe that these putatively *sui generis* elements also raise their head in Meillassoux's contribution in this volume. Having criticised advocates of so-called ‘anthropic reasoning’ for championing a neo-finalism on the grounds of ‘astonishment’, and having castigated Goodman for justifying induction on the grounds of the ‘absurdness’ of the alternative, Meillassoux himself ratifies his radical retraction of the Lucretian principle that ‘nothing can come from nothing’ with an appeal to ‘new situations, whose qualitative content is such that it seems impossible to detect, *without absurdity* [emphasis added], its anticipated presence in anterior situations’, giving as an example the fact that ‘a life endowed with sensibility’ could not, ‘short of sheer fantasy’, emerge from matter as conceived by mathematical physics.

How not to see in this dedication to radical novelty the ‘good sense’ – however exalted – of a grand style in French philosophy which has ever striven to reconcile a rigourous engagement with modern science with the moral exigency of an absolute sovereignty and freedom of thought? As Brassier points out, correlationism runs deep, and it may be difficult to break its circle without also subverting this neo-Cartesianism. And the requisite lifting of the proscription on the ‘objectivation of thought’ would require that philosophy take seriously the research programmes of neuroscience and cognitive science, and hold in abeyance any decision as to thought's putative 'irreducibility'.[4]

Certainly, Churchland holds any such rash decision in suspense, arguing that a study of the history of science gives us every reason to bracket our local conditions and to say with him: 'I agree … it is *hard to imagine* … [b]ut I am unimpressed by this'. One cannot help but feel that Churchland thus modestly inherits the boldest speculative enterprise of philosophy in the twentieth century: to reconcile scientific realism with evolutionary epistemology; to capture the vagaries of 'our' access to things as a *datum* rather than exalting it as an insuperable 'condition'; to reverse the humanity-function so as to accede to an unconditioned knowledge of nature 'itself'.

The apparently pleonastic 'speculative realism' only makes sense when we realise that here the ouroborian figure philosophy has grappled with since the birth of Galileanism is negotiated not by asserting the 'primacy' of one part of the unbroken circle over another, nor by anticipating an eventual accomplishment and unification, but rather by focusing on the process of autophagy itself in action. The two moments of such a programme are, firstly, the account *as datum* of the real conditions of our experience (a technical task descended from Kant's 'transcendental philosophy' as 'the idea of a science')[5] and secondly their effective neutralisation within our self-image (a cultural process). In two different ways – in the resistance of nature to our scientific theorising, and in our own intuitive resistance to the absorption of those theories – it is the recalcitrance of our cognitive constitution that poses a natural obstacle. But as Churchland insists, there is no reason to think this obstacle insuperable in principle.

[5] *Critique of Pure Reason*, tr. N. K. Smith (London: MacMillan 1929), A13/B27.

Just as the philosophical contributors to this volume draw afresh upon the philosophical tradition, so CLÉMENTINE DUZER and LAURA GOZLAN in their film *Nevertheless Empire* have returned to the traditions of expressionism and *noir*, as well as to later enigmatic figures such as Tarkovski, in order to create a science fiction which – as an exemplary instance of the genre – is a speculative portrait of the present, an extrapolation of the twenty-first century amalgam of social dysfunction, generalised fear, and techno-medical monstrosity. As well as maintaining that cinema was itself a very particular way of thinking, Deleuze wrote that 'a book of philosophy should be in part […] a kind of science-fiction.'[6] To present a film, in a volume of philosophy, as a series of stills, represents a further convolution of this complex relationship between thought and image. But this 'stuttering' finds its own consistency on the page, the momentary glimpses reforming in new depths.

In his contribution 'Islamic Exotericism', as in Volume I's 'Militarization of Peace', REZA NEGARESTANI petitions for the adoption of the term 'affordance' into the philosophical vocabulary. Negarestani traces the asymmetry of the 'War on Terror''s landscape of fear, and the shifting apocalyptic narratives engendered by the situation, to the refusal of affordance implicit in Islamic theology.

---

[6] G. Deleuze, *Difference and Repetition*, trans.Paul Patton (London: Athlone,1994),xx.

KRISTEN ALVANSON's photo/diagrammatic essay emphasises a concrete locus for this difference in the theological image of thought: the graveyard as a 'staging of ontology' betrays once again the patterns of affordance, the exigency of survival inherent to Western thinking even in death. Alvanson's inquiry thus forms a concrete counterpart to Negarestani's theological disquisition.

According to Negarestani, through its spatial and temporal approaches to God and Apocalypse, Islamic theology formulates a methodology for the construction of a politically profound tool capable of turning theology itself into heresy. Where Meillassoux uses a rationality unbounded by real necessity to absolutize its own limits, 'touching' itself in a movement of intellectual intuition, Negarestani shows how theology can be reinvented as an epistemological tool for confronting a pure externality, without reducing it to ontological possibilities or to an object of 'affordance'. One might then say that the insubordinable externality Negarestani describes is cognate with the absolute time proposed by Meillassoux – a beyond of chronology, from which irrupt events in principle unpredictable by statistical or economical reason. This is perhaps the most surprising of the many subterranean connections linking the various contributions to this volume of **COLLAPSE**: Do a desacralized thinking of the infinite subtracted from the expectation of mystical union and a proper place for man, and a hyper-rationalism which refuses to bend to real necessity, deliver us to this Now of eternal externality, from which nothing may be expected? Does the conversion of god into a heresy invoke the divine inexistence?

Obviously, it has only been possible in this brief introduction to give a very selective and superficial survey of a volume which suggests so many rich vectors of philosophical thought and so many fascinating possibilities. But we hope to have lightly sketched a portrait here of the underlying conviction, expressed forcefully in so many different voices – and in an age where institutions and publications seem to take pride in cleaving to narrow specialisms – that philosophy, in gloriously unqualified form, is still possible.

In concluding, we would like offer our thanks to our contributors for their generous collaboration on this volume, and to our readers for their enthusiastic response to Volume I. This reception encourages us in our belief that our experiment constitutes a necessary eccentricity in relation to the mainstream – and that in some way it helps set free some of the latent force of philosophical thought – once more 'to resume the offensive'.[7]

The Enigma of Realism: On Quentin Meillassoux's *After Finitude*[1]

Ray Brassier

1. THE ARCHE-FOSSIL

Quentin Meillassoux has recently proposed a compelling diagnosis of what is most problematic in post-Kantian philosophy's relationship to the natural sciences.[2] The former founders on the enigma of the 'arche-fossil'. A fossil is a material bearing the traces of pre-historic life, but an 'arche-fossil' is a material indicating traces of 'ancestral' phenomena anterior even to the emergence of life. It provides the material basis for experiments yielding estimates of ancestral phenomena – such as, for instance, the radioactive isotope whose rate of decay provides an index of the age of rock samples, or the starlight whose luminescence provides an index of the age of distant stars. Natural science produces ancestral statements, such as, for example, that the universe is roughly 13.7 billion years old, that the earth formed roughly 4.5 billion years ago, that life

developed on earth approximately 3.5 billion years ago, and that the earliest ancestors of the genus *Homo* emerged about 2 million years ago.[3] Yet it is also generating an ever increasing number of 'descendent' statements, such as that the Milky Way will collide with the Andromeda galaxy in 3 billion years, or that the earth will be incinerated by the sun 4 billions years hence, or that all the stars in the universe will stop shining in 100 trillion years, or that eventually, one trillion, trillion, trillion years from now, all matter in the cosmos will disintegrate into unbound elementary particles. Philosophers should be more astonished by such statements than they seem to be, for they present a serious problem for post-Kantian philosophy. Yet strangely, the latter seems to remain entirely oblivious to it. The claim that these statements are philosophically enigmatic has nothing to do with qualms about the methods of measurement involved, or with issues of empirical accuracy, or any other misgivings about scientific methodology. They are enigmatic because of the startling philosophical implications harboured by their literal meaning. For the latter seems to point to something which violates the basic conditions of conceptual intelligibility stipulated by post-Kantian philosophy. In order to understand why this is so, we need to try to sketch the latter.

For all their various differences, post-Kantian philosophers can be said to share one fundamental conviction: that the idea of a world-in-itself, subsisting independently of our relation to it, is an absurdity. Objective reality must be transcendentally guaranteed, whether by pure consciousness, intersubjective consensus, or a community of rational agents; without such guarantors, it is a metaphysical chimera. Or for those who scorn what they mockingly dismiss as the 'antiquated' Cartesian vocabulary of 'representationalism', 'subject/object dualism', and epistemology more generally, it is our pre-theoretical relation to the world, whether characterized as *Dasein* or 'Life', which provides the ontological precondition for the intelligibility of the scientific claims listed above. No wonder, then, that post-Kantian philosophers routinely patronize these and other scientific assertions about the world as impoverished abstractions whose meaning supervenes on this more fundamental sub-representational or pre-theoretical relation to phenomena. For these philosophers, it is this relation to the world – *Dasein*, Existence, Life – which provides the originary condition of manifestation for all phenomena, including those ancestral phenomena featured in the statements above. Thus if the idea of a world-in-itself, of a realm of phenomena subsisting independently of our relation to it, is intelligible at all, it can only be intelligible as something in-itself or independent 'for-us'. This is the reigning *doxa* of post-metaphysical philosophy: what is fundamental is neither a hypostasized substance, nor the reified subject, but rather the relation between un-objectifiable thinking and un-representable being, the primordial reciprocity or 'co-propriation' of *logos* and *physis* which at once unites and distinguishes the terms which it relates. This premium on relationality in post-metaphysical philosophy – whose telling symptom is the preoccupation with 'difference' – has become an orthodoxy which is all the more insidious for being constantly touted as a profound innovation.[4]

---

[3] 'Billion' and 'trillion' will be used throughout following their now internationally accepted US usage, as meaning a thousand million and a million million respectively.

Meillassoux has given it a name: 'correlationism'. Correlationism affirms the indissoluble primacy of the relation between thought and its correlate over the metaphysical hypostatization or representationalist reification of either term of the relation. Correlationism is subtle: it never denies that our thoughts or utterances *aim at* or *intend* mind-independent or language-independent realities; it merely stipulates that this apparently independent dimension remains internally related to thought and language. Thus contemporary correlationism dismisses the problematic of scepticism, and of epistemology more generally, as an antiquated Cartesian hang-up: there is supposedly no problem about how we are able to adequately represent reality, since we are 'always already' outside ourselves and immersed in or engaging with the world (and indeed, this particular platitude is constantly touted as the great Heideggerian–Wittgensteinian insight).

---

[4] Graham Harman has elaborated a profound critique of this tendency in contemporary philosophy, seeing in it an avatar of a generalized anti-realism. Whether the relation in question is the epistemological relation between mind and world, the phenomenological relation between noesis and noema, the ekstatic relation between *Sein* and *Dasein*, the prehensive relation between event-objects, or the processual relation between matter and memory, Harman argues that this premium on relationality occludes the discontinuous reality of objects in favour of their reciprocal idealizations. Harman's startlingly original interpretation of Heidegger provides the point of departure for his complete re-orientation of phenomenology away from the primacy of the human relation to things and toward things themselves considered independently of their relation to humans or each other. Accordingly, the fundamental task for this 'object-oriented philosophy' consists in explaining how autonomous objects can ever interact with each other, and to that end Harman has developed a particularly ingenious theory of 'vicarious causation' – See Harman's contribution to the present volume, 171-205.

Note that correlationism need not privilege 'thinking' or 'consciousness' as the key relation – it can just as easily replace it with 'being-in-the-world', 'perception', 'sensibility', 'intuition', 'affect', or even 'flesh'. Indeed, all of these terms have featured in the specifically phenomenological varieties of correlationism.[5]

But the arche-fossil presents a quandary for the correlationist. For how is the correlationist to make sense of science's ancestral claims? Correlationism insists that there can be no cognizable reality independently of our relation to reality; no phenomena without some transcendental operator – such as life or consciousness or *Dasein* – generating the conditions of manifestation through which phenomena manifest themselves. In the absence of this originary relation and these transcendental conditions of manifestation, nothing can be manifest, apprehended, thought or known. Thus, the correlationist will continue, not even the phenomena described by the sciences are possible independently of the relation through which phenomena become manifest. Moreover, the correlationist will add, it is precisely the transcendental nature of the correlation as *sine qua non* for cognition that obviates the possibility of empirical idealism. Thus, *contra* Berkeley, Kant maintains that known things are not dependent upon being perceived precisely because known things are representations and representations are generated via transcendental syntheses of categorial form and sensible material. Synthesis is rooted in pure apperception, which yields the transcendental form of the object as its necessary correlate and guarantor of objectivity. The transcendental object is not cognizable, since it provides the form of objectivity which subsumes all cognizable objects; all of which must be linked to one another within the chains of causation encompassed by the unity of possible experience and circumscribed by the reciprocal poles of transcendental subject and transcendental object. Yet the arche-fossil indexes a reality which does not fall between these poles and which refuses to be integrated into the web of possible experience linking all cognizable objects to one another, because it occurred in a time *anterior to the possibility of experience*. Thus the arche-fossil points to a cognizable reality which is not given in the transcendental object of possible experience. This is a possibility which Kant explicitly denies:

---

[5] The writings of Husserl and Heidegger are littered with paradigmatic expressions of the correlationist credo. Here are just two examples:

> The existence of Nature *cannot* be the condition for the existence of consciousness, since Nature itself turns out to be a correlate of consciousness: Nature *is* only as being constituted in regular concatenations of consciousness. (Edmund Husserl, *Ideas Pertaining to a Pure Phenomenology and to a Phenomenological Philosophy. Book One*. Tr. F. Kersten, Dordrecht, The Netherlands: Kluwer, 1982: 116).

> [S]trictly speaking we cannot say: there was a time when there were no human beings. At every *time*, there were and are and will be human beings, because time temporalizes itself only as long as there are human beings. There is no time in which there were no human beings, not because there are human beings from all eternity, but because time is not eternity, and time always temporalizes itself only at one time, as human, historical Dasein. (Martin Heidegger, *Introduction to Metaphysics*, tr. G. Fried and R. Polt, New Haven and London: Yale University Press, 2000: 88-9).

> Thus we can say that the real things of past time are given in the transcendental object of experience; but they are objects for me and real in past time only in so far as I represent to myself (either by the light of history or by the guiding clues of a series of causes and effects) that a

> regressive series of possible perceptions in accordance with empirical laws, in a word, that the course of the world, conducts us to a past time-series as the condition of the present time – a series which, however, can be represented as actual not in itself but only in the connection of a possible experience. *Accordingly, all events which have taken place in the immense periods that have preceded my own existence really mean nothing but the possibility of extending the chain of experience from the present perception back to the conditions which determine this perception in respect of time*.[6]

For Kant, then, the ancestral time of the arche-fossil cannot be represented as existing in itself but only as connected to a possible experience. But we cannot represent to ourselves any regressive series of possible perceptions in accordance with empirical laws capable of conducting us from our present perceptions to the ancestral time indexed by the arche-fossil. It is strictly impossible to prolong the chain of experience from our contemporary perception of the radioactive isotope to the time of the accretion of the earth indexed by its radiation, because the totality of the temporal series coextensive with possible experience itself emerged out of that geological time wherein there simply was no perception. We cannot extend the chain of possible perceptions back prior to the emergence of nervous systems, which provide the material conditions for the possibility of perceptual experience.

Thus it is precisely the necessity of an originary correlation, whether between knower and known, or *Sein* and *Dasein*, that science's ancestral statements flatly contradict. For in flagrant disregard of those transcendental conditions which are supposed to be necessary for every manifestation, they describe occurrences anterior to the emergence of life, and objects existing independently of any relation to thought. Similarly, science's descendent statements refer to events occurring after the extinction of life and the annihilation of thought. But how can such statements be true if correlationism is sound? For not only do they designate events occurring quite independently of the existence of life and thought; they inscribe the transcendental conditions of manifestation themselves within a merely empirical timeline. How can the relation to reality embodied in life or thought be characterized as transcendentally necessary (*sine qua non*) for the possibility of spatiotemporal manifestation when science unequivocally states that life and thought, and hence this fundamental relation, have a determinate beginning and end in space-time? Don't science's ancestral and descendent statements strongly imply that those ontologically generative conditions of spatiotemporal manifestation privileged by correlationists – *Dasein*, life, consciousness, and so on – are themselves merely spatiotemporal occurrences like any other?

2. THE CORRELATIONIST RESPONSE

Confronted by Meillassoux's argument from the arche-fossil, partisans of correlationism have not been slow in mounting a counter-offensive. In a supplement to the forthcoming English translation of *Après la finitude*, Meillassoux recapitulates the two most frequently voiced objections and responds to both. The correlationist defence is two-tiered. In the first stage, Meillassoux is accused of inflating an un-observed phenomenon into a negation of correlation, when in fact it is merely a lacuna in correlation. In the second stage, Meillassoux is deemed guilty of naively conflating the empirical and the transcendental. We will consider each of these objections, as well as Meillassoux's responses to them, in turn.

In the first stage, the correlationist contends that, far from being novel and challenging, the argument from the arche-fossil is merely a restatement of a hackneyed and rather feeble objection to transcendental idealism. Thus, the correlationist continues, the arche-fossil is simply an example of a phenomenon which went un-perceived. But un-perceived phenomena occur all the time and it is excessively naive to think they suffice to undermine the transcendental status of the correlation. In this regard, the temporal distance which separates us from the ancestral phenomenon is no different in kind from the spatial distance which separates us from contemporaneous but unobserved events occurring elsewhere in the universe. Thus the fact that there was no-one around 4.5 billion years ago to perceive the accretion of the earth is no more significant than the fact that there is currently no-one 25 million, million miles away perceiving events on the surface of Alpha Centauri. Moreover, the notion of 'distance' is an inherently ambiguous and unreliable indicator of the limits of perception: technology allows us to perceive objects extraordinarily far away in space and time, while myriad occurrences close at hand routinely go unperceived. In this regard, instances of spatiotemporal extremity are no different in kind from other banal instances of un-witnessed or un-perceived phenomena, such as the fact that we are never aware of everything going on inside our own bodies. Thus the arche-fossil is just another example of an un-perceived phenomenon and, as with all other examples of un-perceived phenomena, it merely exemplifies the inherently *lacunary* nature of manifestation – the fact that no phenomenon is ever exhaustively or absolutely apprehended by perception or consciousness. Far from denying this, both Kant and Husserl emphasized the intrinsically limited and finite nature of human cognition. Thus for Kant sensible intuition is incapable of exhaustively apprehending the infinite complexity of a datum of sensation. Similarly for Husserl, intentionality proceeds by adumbrations which never exhaust all the dimensions of the phenomenon. But the fact that every phenomenon harbours an un-apprehended remainder in no way undermines the constitutive status of transcendental consciousness. All that it shows is that manifestation is inherently lacunary and that the non-manifest inheres in every manifestation. A counterfactual suffices to establish the persistence of transcendental constitution even in cases of lacunary manifestation such as the arche-fossil. Thus the contingent fact that no-one was there to witness the accretion of the earth is ultimately of no importance; for *had there been* a witness, they *would have* perceived the phenomenon of accretion unfolding in conformity with the laws of geology and physics which are transcendentally guaranteed by the correlation. Ultimately, the correlationist concludes, the argument from the arche-fossil fails to challenge correlationism because it has simply confused a contingent lacuna in manifestation with the necessary absence of manifestation.

Against this initial line of defence, Meillassoux insists that the arche-fossil cannot be reduced to an example of the un-perceived because the temporal anteriority involved in the notion of ancestrality remains irreducible to any notion of temporal 'distance' concomitant with correlational manifestation. To reduce the arche-fossil to an un-witnessed or un-perceived occurrence is to beg the question because it is to continue to assume that there is always a correlation in terms of which to measure gaps or lacunae within manifestation. But the arche-fossil is not merely a non-manifest gap or lacuna *in* manifestation; it is the lacuna *of* manifestation *tout court.* For the anteriority indexed by the ancestral phenomenon does not point to an earlier time *within* manifestation; it indexes a time *anterior to the time of manifestation in its entirety*; and it does so according to a sense of 'anteriority' which cannot be reduced to the past of manifestation because it indicates a time wherein manifestation – along with its past, present, and future dimensions – originally emerged. Thus, Meillassoux contends, the 'ancestral' cannot be reduced to the 'ancient'. There are always greater or lesser degrees of 'ancientness' depending on whatever temporal metric one happens to choose. 'Ancientness' remains a function of a relation between past and present which is entirely circumscribed by the conditions of manifestation and in this sense any past, no matter how 'ancient', remains synchronous with the correlational present. In equating temporal remove with spatial distance, the correlationist objection outlined above continues to assume this underlying synchronicity. But ancestrality indexes a radical 'diachronicity' which cannot be correlated with the present because it belongs to the time wherein the conditions of correlation between past, present, and future passed from inexistence into existence. Accordingly, ancestrality harbours a temporal diachronicity which remains incommensurable with any chronological measure that would ensure a reciprocity between the past, present, and future dimensions of the correlation.

Meillassoux detects in this initial correlationist response a subterfuge which consists in substituting a lacuna *in* and *for* manifestation – a lacuna that is contemporaneous with constituting consciousness, as is always the case with the un-perceived – for a lacuna *of* manifestation as such; one which cannot be synchronized with constituting consciousness (or whatever other transcendental operator happens to be invoked). The correlationist's sleight-of-hand here consists in reducing the arche-fossil – which is non-manifest insofar as it occurs prior to the emergence of conditions of manifestation – to the un-perceived, which is merely a measurable gap or absence within the extant conditions of manifestation. However, Meillassoux insists, the arche-fossil is neither a lacunary manifestation nor a temporal reality internal to manifestation (internal to the correlation); for it points to the temporal reality in which manifestation itself first came into existence, and wherein it will ultimately sink back into inexistence. Consequently, Meillassoux concludes, it is a serious misunderstanding to think that a counterfactual suffices to reintegrate the arche-fossil within the correlation, for the diachronicity it indexes cannot be synchronized with any correlational present.

Having failed to rebuff the argument from the arche-fossil with this initial line of defence, the correlationist adopts a second strategy. This consists in contesting the claim that ancestrality indexes a temporal dimension within which correlational temporality itself passes into and out of being. For such an assertion betrays a fundamental confusion between the *transcendental* level at which the conditions of correlation obtain and the *empirical* level at which the organisms and/or material entities which support those conditions exist. The latter are indeed spatiotemporal objects like any other, emerging and perishing within physical space-time; but the former provide the conditions of objectivation without which scientific knowledge of spatiotemporal objects – and hence of the arche-fossil itself – would not be possible. Though these conditions are physically instantiated by specific material objects – *i.e.* human organisms – they cannot be said to exist in the same manner, and hence they cannot be said to pass into or out of existence on pain of paralogism. Thus, the correlationist continues, the claim that the conditions of objectivation emerged in space-time is an absurd paralogism because it treats transcendental conditions as though they were objects alongside other objects. But the transcendental conditions of spatiotemporal objectivation do not exist spatiotemporally. This is not to say that they are eternal, for this would be to hypostatize them once again and to attribute another kind of objective existence to them, albeit in a transcendent or supernatural register. They are neither transcendent nor supernatural – they are the logical preconditions for ascriptions of existence, rather than objectively existing entities. As conditions for the scientific cognition of empirical reality – of which the arche-fossil is a prime example – they cannot themselves be scientifically objectified without engendering absurd paradoxes. The claim that ancestral time encompasses the birth and death of transcendental subjectivity is precisely such a paradox, but one which dissolves once the confusion from which it has arisen has been diagnosed.

Yet for Meillassoux, the initial plausibility of this response masks its underlying inadequacy, for it relies on an unacknowledged equivocation. We are told that transcendental subjectivity cannot be objectified, and hence that it neither emerges nor perishes in space-time; but also that it is neither immortal nor eternal, in the manner of a transcendent metaphysical principle. Indeed this is precisely what distinguishes transcendental subjectivity in its purported finitude from any metaphysical hypostatization of the principle of subjectivity which would render it equivalent to an infinitely enduring substance. But as finite, transcendental subjectivity is indissociable from the determinate set of material conditions which provide its empirical support. Thus Husserl insists on the necessary parallelism which renders the transcendental indissociable from the empirical. Indeed, it is this necessary parallelism which distinguishes transcendental subjectivity from its metaphysical substantialization. Accordingly, though transcendental subjectivity is merely instantiated in the minds of physical organisms, it cannot subsist independently of those minds and the organisms which support them. Although it does not exist in space and time, it has no other kind of existence apart from the spatiotemporal existence of the physical bodies in which it is instantiated. And it is precisely insofar as it is anchored in the finite minds of bounded physical organisms with limited sensory and intellectual capacities that human reason is not infinite. But if transcendental subjectivity is necessarily instantiated in the spatiotemporal existence of physical organisms, then it is not quite accurate to claim that it can be entirely divorced from objectively existing bodies. Indeed, in the wake of Heidegger's critique of the 'worldless' or disembodied subject of classical transcendentalism, post-Heideggerean philosophy can be said to have engaged in an increasing 'corporealization' of the transcendental. Merleau-Ponty is probably the most prominent (though certainly not the only) advocate of the quasi-transcendental status of embodiment. Accordingly, although transcendental subjectivity may not be reducible to objectively existing bodies, neither can it be divorced from them, for the existence of bodies – and *a fortiori* of language, society, history, culture, etc. – provides the conditions of instantiation for the transcendental (i.e. the 'always already'). Thus, Meillassoux concludes, while it is perfectly plausible to insist that the correlation provides the transcendental condition for knowledge of spatiotemporal existence, it is also necessary to point out that the time in which the bodies that provide the conditions of instantiation for the correlation emerge and perish is also the time which determines the conditions of instantiation of the transcendental. But the ancestral time which determines the conditions of instantiation of the transcendental cannot be encompassed within the time that is co-extensive with the correlation, because it is the time within which those corporeal conditions upon which the correlation depends pass into and out of existence. Where such conditions of instantiation are absent, so is the correlation. Thus the ancestral time indexed by the arche-fossil is simply the time of the inexistence of the correlation. This ancestral time is indexed by objective phenomena such as the arche-fossil; but its existence does not depend upon those conditions of objectivation upon which knowledge of the arche-fossil depends, because it determines those conditions of instantiation which determine conditions of objectivation.

3. Ancestrality and Chronology

Meillassoux's responses to his correlationist critics are as trenchant as they are resourceful and they undoubtedly constitute a significant addition to his already weighty case against correlationism. However, they also invite a number of critical observations. First, it is not at all clear how Meillassoux's distinction between ancestrality and spatiotemporal distance can be squared with what twentieth-century physics has taught us concerning the fundamental indissociability of time and space, as enshrined in the Einstein-Minkowski conception of four-dimensional space-time. 'Anteriority' and 'posteriority' are inherently relational terms which can only be rendered intelligible from within a spatiotemporal frame of reference. In this regard, Meillassoux's insistence on the irreconcilable disjunction between a lacuna *in* manifestation and the lacuna *of* manifestation continues to rely on an appeal to the scalar incommensurability between the anthropomorphic time privileged by correlationism and the cosmological time within which the former is nested. This incommensurability is attributed to the fundamental asymmetry between cosmological and anthropomorphic time: whereas the former is presumed to encompass the beginning and end of the latter, the reverse is assumed not to be the case. However, Meillassoux conducts his case against correlationism in a logical rather than empirical register – indeed, we shall see below how this leads him to reiterate the dualism of thought and extension – yet the asymmetry to which he appeals here is precisely a function of empirical fact, and as Meillassoux himself acknowledges,[7] there is no *a priori* reason why the existence of mind, and hence of the correlation, could not happen to be coextensive with the existence of the universe. Indeed, this is precisely the claim of Hegelianism, which construes mind or *Geist* as a self-relating negativity already inherent in material reality. Accordingly, the transcendence which Meillassoux ascribes to ancestral time as that which exists independently of correlation continues to rely upon an appeal to chronology: it is the (empirical) fact that cosmological time *preceded* anthropomorphic time and will presumably *succeed* it which is invoked in the account of the asymmetry between the two. In light of this implicit appeal to chronology in Meillassoux's claim that the arche-fossil indexes the absence of manifestation, rather than any hiatus within it, it is difficult to see how the temporal anteriority which he ascribes to the ancestral realm could ever be understood wholly independently of the spatiotemporal framework in terms of which cosmology coordinates relations between past, present, and future events. A simple change in the framework which determines chronology would suffice to dissolve the alleged incommensurability between ancestral and anthropomorphic time, thereby bridging the conceptual abyss which is supposed to separate anteriority from spatiotemporal distance.

---

[7] *Cf. Après la finitude*, 161.

The conclusion to be drawn is the following: as long as the autonomy of the in-itself is construed in terms of a merely chronological discrepancy between cosmological and anthropomorphic time, it will always be possible for the correlationist to convert the supposedly absolute anteriority attributed to the ancestral realm into an anteriority which is merely 'for us', not 'in itself'. By tethering his challenge to correlationism to the spatiotemporal framework favoured by contemporary cosmology, Meillassoux mortgages the autonomy of the in-itself to chronology. The only hope for securing the unequivocal independence of the '*an sich*' must lie in prizing it free from chronology as well as phenomenology. This would entail a conception of objectivity which excludes chronological relationality as much as phenomenological intentionality. Spatiotemporal relations should be construed as a function of objective reality; rather than objective reality construed as a function of spatiotemporal relations. By insisting on driving a wedge between ancestral time and spatiotemporal distance, Meillassoux inadvertently reiterates the privileging of time over space which is so symptomatic of idealism and unwittingly endorses his opponents' claim that all non-ancestral reality can be un-problematically accounted for by the correlation. Thus the trenchancy of Meillassoux's rejoinders above actually masks a significant concession to correlationism. For surely it is not just ancestral phenomena which challenge the latter, but simply the reality described by the modern natural sciences *tout* *court.* According to the latter, we are surrounded by processes going on quite independently of any relationship we may happen to have to them: thus plate tectonics, thermonuclear fusion, and galactic expansion (not to mention undiscovered oil reserves or unknown insect species) are as much autonomous, human-independent realities as the accretion of the earth. The fact that these processes are contemporaneous with the existence of consciousness, while the accretion of the earth preceded it, is quite irrelevant. To maintain the contrary, and insist that it is only the ancestral dimension that transcends correlational constitution, is to imply that the emergence of consciousness marks some sort of fundamental ontological rupture, shattering the autonomy and consistency of reality, such that once consciousness has emerged on the scene, nothing can pursue an independent existence any more. The danger is that in privileging the arche-fossil as sole paradigm of a mind-independent reality, Meillassoux is ceding too much ground to the correlationism he wishes to destroy.[8]

3. THE PRINCIPLE OF FACTUALITY

Meillassoux distinguishes between two varieties of correlationism: weak correlationism, which claims that we can *think* noumena even though we cannot *know* them, and strong correlationism, which claims that we cannot even think them. Weak correlationism, exemplified by Kant, insists on the finitude of reason and the conditional nature of our access to being. The conditions for knowledge (the categories and forms of intuition) apply only to the phenomenal realm, not to things in-themselves. Thus the cognitive structures governing the phenomenal realm are not necessary features of things-in-themselves. We cannot know why space and time are the only two forms of intuition or why there are twelve rather than eleven or thirteen categories. There is no sufficient reason capable of accounting for such a fact. In this sense, and this sense alone, these transcendental structures are contingent. But Hegel will point out that Kant has already overstepped the boundary between the knowable and the unknowable in presuming to know that the structure of things-in-themselves differs from the structure of phenomena. Accordingly, Hegel will proceed to re-inject that which is transcendentally constitutive of the 'for us' back into the 'in-itself'. Thus in Hegel's absolute idealism thinking grounds its own access to being once more and rediscovers its intrinsic infinitude. Where Kant's weak correlationism emphasises the uncircumventable contingency inherent in the correlation between thinking and being, Hegelianism absolutizes the correlation and thereby insists on the necessary isomorphy between the structure of thinking and that of being. In this regard, strong correlationism, which encompasses everything from phenomenology to pragmatism, can be understood as a critical rejoinder to the Hegelian absolutization of correlation. Though strong correlationism also jettisons the thing-in-itself, it retains the Kantian premium on the ineluctable contingency of the correlation, which Heidegger famously radicalizes in the notion of 'facticity'. Thus strong correlationism, as exemplified by figures such as Heidegger and Foucault, insists – contra Hegel – that the contingency of correlation cannot be rationalised or grounded in reason. This is the anti-metaphysical import of Heidegger's epochal 'history of being' or of Foucault's 'archaeologies of knowledge'. Accordingly, if we are to break with correlationism, we must re-legitimate the possibility of thinking the thing-in-itself, yet do so without either absolutizing correlation or resorting to the Principle of Sufficient Reason.

---

[8] I am indebted to Graham Harman, Robin Mackay, and Damian Veal for all these critical points.

In a remarkable *tour de force*, Meillassoux shows how what is most powerful in strong correlationism can be used to overcome it from within. And what is most powerful in it is precisely its insistence on the facticity of correlation. For on what basis does strong correlationism reject the Hegelian rehabilitation of the Principle of Sufficient Reason – the claim that contradiction is the ground of being – and the ensuing isomorphy between thinking and being? It does so by insisting on the facticity or non-necessity of correlation against its Hegelian absolutization – thought's access to being is extrinsically conditioned by non-conceptual factors, which cannot be rationalised or reincorporated within the concept, not even in the form of dialectical contradiction. Thus, in order to emphasize the primacy of facticity against the speculative temptation to absolutize correlation, strong correlationism must insist that everything is without reason – even correlation itself. Against Hegel's speculative idealism, which seeks to show how the correlation can demonstrate its own necessity by grounding itself, thereby becoming absolutely necessary or *causa sui*, strong correlationism must maintain that such self-grounding is impossible by demonstrating that the correlation cannot know itself to be necessary. For though we can claim that an empirical phenomenon is necessary or contingent in conformity with the transcendental principles governing the possibility of knowledge, we cannot know whether these principles themselves are either necessary or contingent, for we have nothing to compare them to. This argument proceeds on the basis of a distinction between contingency, which is under the jurisdiction of knowledge, and facticity, which is not. Contingency is empirical and pertains to phenomena: a phenomenon is contingent if it can come into or out of existence without violating the principles of cognition that govern phenomena. Facticity is transcendental and pertains to our cognitive relation to phenomena, and hence to the principles of knowledge themselves, concerning which it makes no sense to say either that they are necessary or that they are contingent, since we have no other principles to compare them to. Against absolute idealism then, strong correlationism insists that to affirm the necessity of the correlation is to contravene the norms of knowledge. Yet in so doing, it violates its own stricture: for in order to claim that the correlation is not necessary, it has no choice but to affirm its contingency.

Accordingly, strong correlationism is obliged to contravene its own distinction between what is knowable and what is unknowable in order to protect it; it must assert the contingency of correlation in order to contradict the idealist's assertion of its necessity. But to affirm the contingency of correlation is also to assert the necessity of facticity and hence to overstep the boundary between what can be known – contingency – and what cannot be known – facticity – in the very movement that is supposed to reassert its inviolability. For in order to maintain the contingency of correlation and stave off absolute idealism, strong correlationism must insist on the necessity of its facticity – but it cannot do so without knowing something which, by its own lights, it is not supposed to know. Thus it finds itself confronted with the following dilemma: it cannot de-absolutize facticity without absolutizing the correlation; yet it cannot de-absolutize the correlation without absolutizing facticity. But to absolutize facticity is to assert the unconditional necessity of its contingency and hence to assert that it is possible to think something that exists independently of thought's relation to it: contingency as such. In absolutizing facticity, correlationism subverts the empirical-transcendental divide separating knowable contingency from unknowable facticity even as it strives to maintain it; but it is thereby forced to acknowledge that what it took to be a negative characteristic of our relation to things – *viz.*, that we cannot know whether the principles of cognition are necessary or contingent – is in fact a positive characteristic of things-in-themselves.

It is worthwhile pausing here to underline the decisive distinction between the idealist and realist variants of the speculative overcoming of correlationism. Speculative idealism claims that the in-itself is not some transcendent object standing 'outside' the correlation, but is rather nothing other than the correlation as such. Thus it converts relationality *per se* into a thing-in-itself or absolute: the dialectician claims that we overcome the metaphysical reification of the in-itself when we realize that what we took to be merely for-us is in fact in-itself. Correlation is absolutized when it becomes in-itself for-itself. But this involves transforming correlation into a metaphysically necessary entity or *causa sui*. By way of contrast, Meillassoux's speculative materialism asserts that the only way to preserve the in-itself from its idealist incorporation into the for-us without reifying it metaphysically is by realizing that what is in-itself is the *contingency* of the for-us, not its necessity. Thus, when facticity is absolutized, it is the contingency or groundlessness of the for-us (the correlation) which becomes in-itself or necessary precisely insofar as its contingency is not something which is merely for-us. Speculative materialism asserts that, in order to maintain our ignorance of the necessity of correlation, we have to know that its contingency is necessary. In other words, if we can never know the necessity of anything, this is not because necessity is unknowable but because we know that only contingency necessarily exists. What is absolute is the fact that everything is necessarily contingent or 'without-reason'.

Consequently, when forced to pursue the ultimate consequences of its own premises, correlationism is obliged to turn our ignorance concerning the necessity or contingency of our knowledge of phenomena into a thinkable property of things-in-themselves. The result, as Meillassoux puts it, is that '[t]he absolute is the absolute impossibility of a necessary being'.[9] This is Meillassoux's 'principle of factuality' and though it might seem exceedingly slight, its implications are far from trivial. For it imposes significant constraints upon thought. If a necessary being is conceptually impossible then the only absolute is the real possibility of the completely arbitrary and radically unpredictable transformation of all things from one moment to the next. It is important not to confuse this with familiar Heraclitean or Nietzschean paeans to absolute becoming, for the latter merely substitutes the metaphysical necessity of perpetual differentiation for the metaphysical necessity of perpetual identity. To affirm the metaphysical primacy of becoming is to claim that it is impossible for things not to change; impossible for things to stay the same; and *ergo* to claim that it is necessary for things to keep changing. The flux of ceaseless becoming is thereby conceived as ineluctable and metaphysically necessary as unchanging stasis. But metaphysical necessity, whether it be that of perpetual flux or of permanent fixity, is precisely what the principle of absolute contingency rules out. The necessity of contingency, Meillassoux maintains, implies an 'absolute time' which can interrupt the flux of becoming with the same arbitrary capriciousness as it can scramble the fixity of being. Absolute time is tantamount to a 'hyper-chaos' for which nothing is impossible, unless it be the production of a necessary being. It is a contingency which usurps every possible order, including the order of disorder or the constancy of inconstancy. It is all-powerful; but an absolute power which is 'without norms, blind, and devoid of all the other divine perfections [...] It is a power possessing neither goodness nor wisdom [...] a time capable of destroying becoming itself by bringing forth, perhaps forever, fixity, stasis, and death'.[10]

4. THE PARADOX OF ABSOLUTE CONTINGENCY

In a move that effectively sidesteps the entire problematic of representation, Meillassoux boldly declares his intention to reinstate intellectual intuition:

> [W]e must project unreason into the thing itself, and discover in our grasp of facticity the veritable intellectual intuition of the absolute. 'Intuition', since it is well and truly in [à même] *what is* that we discover a contingency with no bounds other than itself; 'intellectual', since this contingency is nothing visible, nothing perceptible in the thing: only thought can access it as it accesses the Chaos which underlies the apparent continuities of phenomena.[11]

The deployment of this presumably non-metaphysical variety of intellectual intuition circumvents Kant's critical distinction between knowable phenomena and unknowable things-in-themselves – between reality as we relate to it through representation and reality as it is independently of our representational relation to it – and rehabilitates the distinction between primary and secondary qualities; the former being mathematically intuitable features of things-in-themselves; the latter being phenomenological features of our relation to things.[12] This reinstatement of intellectual intuition is of a piece with Meillassoux's overturning of Kant's critical delimitation of the possibilities of reason. Intellectual intuition now provides us with direct access to a realm of pure possibility coextensive with absolute time. Kant displaced the metaphysical hypostatization of logical possibility by subordinating the latter to a domain of real possibility circumscribed by reason's relation to sensibility. Time *qua* form of transcendental synthesis grounds the structure of possibility.[13] But Meillassoux's absolutization of contingency effectively absolutizes the *a priori* realm of pure logical possibility and untethers the domain of mathematical intelligibility from sensibility. This severing of the possible from the sensible is underwritten by the chaotic structure of absolute time. Where the bounds of real possibility remain circumscribed by the correlational *a priori*, intellectual intuition uncovers a realm of absolute possibility whose only constraint is non-contradiction. Moreover, where real possibility is subsumed by time as form of transcendental subjectivity, absolute possibility indexes a time no longer anchored in the coherence of a subjective relation to reality or in the correlation between thinking and being. Thus the intellectual intuition of absolute possibility underwrites the 'diachronicity' of thinking and being; a diachronicity which for Meillassoux is implicit in the ancestral dimension of being uncovered by modern science. In ratifying the diachronicity of thinking and being, modern science exposes thought's contingency for being: although thought needs being, being does not need thought.

---

[11] *Ibid.*, 111.

[12] *Ibid.*, 28.

The question, then, is whether Meillassoux's reinstatement of intellectual intuition may not compromise the very asymmetry which he takes to be science's speculative import. Similarly, it may be that the Galilean hypothesis harbours ramifications concerning the mathematization of thinking which also vitiate Meillassoux's appeal to intellectual intuition. To consider these questions, we must examine the distinction which Meillassoux invokes in order to stave off idealism. This is the distinction between the reality of the ancestral phenomenon and the *ideality* of the ancestral statement. It is on the basis of this distinction that Meillassoux, like Badiou, seeks to distance himself from the Pythagorean thesis according to which being is mathematical:

---

[13] This is the upshot of Heidegger's reinterpretation of Kant in *Kant and the Problem of Metaphysics*, tr. R. Taft (Indianapolis: Indiana University Press, 1990).

> [W]e will maintain that, for their part, the statements bearing on the ancestral phenomenon which can be mathematically formulated designate effective properties of the event in question (its date, its duration, its extension), even though no observer was present to experience it directly. Accordingly, we will maintain a Cartesian thesis about matter, but not, let us underline this, a Pythagorean one: we shall not claim that the being of the ancestral phenomenon is intrinsically mathematical, or that the numbers and equations deployed in ancestral statements exist in themselves. For it would then be necessary to maintain that the ancestral phenomenon is a reality every bit as ideal as that of a number or an equation. Generally speaking, statements are ideal insofar as they possess a signifying reality; but their eventual referents are not necessarily ideal (the cat on the mat is real, though the statement 'The cat is on the mat' is ideal.) In this regard, we will say that the referents of ancestral statements bearing on dates, volumes, etc. existed 4.56 billion years ago as described by these statements – but not these statements themselves, which are contemporaneous with us.[14]

---

[14] *Après la finitude*, 28-9.

This distinction between the reality of the ancestral phenomenon and the ideality of the ancestral statement is necessary in order to maintain the ontological disjunction between the correlational present and the ancestral past – precisely the diachronicity which correlationism cannot countenance. Nevertheless, if Meillassoux evokes such a distinction, he cannot sequester it on the side of being alone, for it must pertain to thinking as well as to being. Thus this secondary disjunction between real and ideal subdivides both poles of the primary disjunction between thinking and being: thought possesses a real and an ideal aspect, just as being possesses real and ideal features. Clearly, the diachronicity harboured by the arche-fossil can only be indexed by a disjunction between the ideality of the ancestral statement and the reality of the ancestral phenomenon which promises to prove irreducible to the neighbouring distinctions between the real and ideal aspect of thought and the real and ideal features of being, for both of these remain entirely encompassed by the correlation between thinking and being. For the point of Meillassoux's distinction between physical reality and discursive ideality is to discount the idealist claim that the reality of the phenomenon is exhausted by its mathematical idealization in the statement. Although the reality of the ancestral phenomenon can be mathematically encoded, it must transcend this mathematical inscription, otherwise Meillassoux finds himself endorsing Pythagoreanism. And as Meillassoux well knows, the latter provides no bulwark against correlationism, since it effectively renders being isomorphic with mathematical ideality. The point seems to be that the reality of the ancestral phenomenon must be independent of its mathematical intellection – being does not depend upon the existence of mathematics. But Meillassoux's problem consists in identifying a speculative guarantor for this disjunction between reality and ideality which would be entirely independent of the evidence provided by the mathematical idealization of the ancestral phenomenon in the ancestral statement. To rely upon the latter would be to render this speculative disjunction supervenient upon the procedures of post-critical epistemology and thus to find oneself confronted by the injunction to verify or otherwise justify it within the ambit of the correlationist circle.

Thus the question confronting Meillassoux's speculative materialism is: under what conditions would this secondary disjunction between the real and the ideal be intellectually intuitable without reinstating a correlation at the level of the primary disjunction between thinking and being? To render the distinction between the reality of the phenomenon and the ideality of the statement dependent upon intellectual intuition is to leave it entirely encompassed by one pole of the primary disjunction, *i.e.* thought, and hence to recapitulate the correlationist circle. For just as we cannot maintain that this primary disjunction is intellectually intuitable without reinscribing being within the ideal pole of the secondary disjunction, similarly, we cannot maintain that the secondary disjunction is encoded in the ancestral statement without reincorporating the real within the noetic pole of the primary disjunction. How, then, are we to guarantee the disjunction between real and ideal independently of the intelligible ideality of science's ancestral claims? For the ideality of the latter cannot be a guarantor of the reality of the former. Moreover, intellectual intuition subsumes both poles of the secondary disjunction within one pole of the primary disjunction.

Consequently, Meillassoux is forced into the difficult position of attempting to reconcile the claim that being is not inherently mathematical with the claim that being is intrinsically accessible to intellectual intuition. He cannot maintain that being is mathematical without lapsing into Pythagorean idealism; but this relapse into Pythagoreanism is precluded only at the cost of the idealism which renders being the correlate of intellectual intuition. The problem lies in trying to square the Galilean-Cartesian hypothesis that being is mathematizable with an insistence on the speculative disjunction whereby being is held to subsist independently of its mathematical intuitability. Part of the difficulty resides in the fact that although Meillassoux presumably discounts metaphysical and phenomenological conceptions of being, whether as necessary substance or eidetic presence, since both are encompassed within the correlationist circle, he has not provided us with a non-metaphysical and non-phenomenological alternative – such as we find, for example, in Badiou's subtractive conception of the void.[15] Like Badiou, Meillassoux recuses the Kantian formulation of the problematic of access while striving to uphold the authority of scientific rationality. However, unlike Badiou, he does not characterize ontology as a situation within which the presentation of being is subtractively inscribed in such a way as to obviate any straightforwardly metaphysical or phenomenological correlation between thought and being.

---

[15] *Cf. Being and Event*, tr. O. Feltham (London: Continuum, 2006).

But as a result he must explain why – given that science teaches us that intellection is in no way an ineliminable feature of reality but merely a contingent by-product of evolutionary history, and given that for Meillassoux himself reality can be neither inherently mathematical nor *necessarily* intelligible – being should be susceptible to intellectual intuition. In this regard, it is worth noting that one of the more significant ramifications of the Galilean-Cartesian hypothesis about the mathematizability of nature consists in the recent endeavour to deploy the resources of mathematical modelization in order to develop a science of cognition. Admittedly, the latter is still in its infancy; nevertheless, its maturation promises to obviate the Cartesian dualism of thought and extension – and perhaps also the residues of the latter which subsist in Meillassoux's own brand of speculative materialism – while conceding nothing to correlationism. The diachronic disjunction between thinking and being is not the only speculative implication harboured by modern science; the development of a science of cognition implies that we, unlike Descartes and Kant, can no longer presume to exempt thought from the reality to which it provides access, or continue to attribute an exceptional status to it.

If thought can no longer be presumed to exempt itself from the reality which it thinks, and if the real can no longer be directly mapped onto being, or the ideal directly mapped onto thought, then thinking itself must be reintegrated into any speculative enquiry into the nature of reality. Thus the central question raised by Meillassoux's speculative materialism becomes: Does the principle of factuality, which states that 'everything that exists is necessarily contingent', *include itself* in its designation of 'everything'? Like Badiou, Meillassoux sees Cantor as having definitively pulverized the concept of 'totality', so that the latter is now devoid of ontological pertinence. But we do not have to assume a spurious totalization of existence to enquire whether the thought that everything is necessarily contingent is itself necessarily contingent. On the contrary, all that we assume is that thinking is just a contingent fact like any other. What we should refuse, however, is the claim that it is necessary to exempt the thought that 'everything is necessarily contingent' from the existential 'fact' that everything is contingent on the grounds that a transcendental abyss separates thinking from being. Once the recourse to this transcendental divide has been ruled out, we are obliged to consider what follows if the principle refers to itself. More precisely, we must consider whether the truth of the principle, and *a fortiori* Meillassoux's speculative overcoming of correlationism, entails its self-reference. Here we have to distinguish between the contingency of the existence of the thought, which does *not* generate paradox, and the contingency of the truth of the thought, which does. Two distinct possibilities can be envisaged depending on whether the thought does or does not refer to itself. First let us consider what follows if it does refer to itself. Then if the thought exists, it must be contingent. But if it is contingent then its negation could equally exist: 'Not everything is necessarily contingent'. But in order for the thought to exclude the possibility of the truth of its negation, then its truth must be necessary, which means that the thought must exist necessarily. But if it exists necessarily then not everything that exists is necessarily contingent; there is at least one thing which is not, *i.e.* the thought itself. Thus if the thought refers to itself it necessitates the existence of its own negation; but in order to deny the possible truth of its negation it has to affirm its own necessary truth, and hence contradict itself once more. What if the thought does not refer to itself? Then there is something which is necessary, but which is not included under the rubric of existence. Reality is 'not-all' because the thought that 'everything is necessarily contingent' is an ideality which exempts itself from the reality which it designates. But then not only does this very exemption become necessary for the intelligible ideality of the thought that 'everything is necessarily contingent', but the intelligibility of reality understood as the necessary existence of contingency becomes dependent upon the coherence of a thought whose exemption from reality is necessary in order for reality to be thought as necessarily contingent. Thus the attempt to exempt the ideal from the real threatens to re-instantiate the correlationist circle once more. Lastly, let us consider the possibility that the necessary contingency of existence does not depend on the truth of the thought 'everything is necessarily contingent'. If everything is necessarily contingent regardless of the truth of the thought 'everything is necessarily contingent', then everything could be necessarily contingent even if we had no way of thinking the truth of that thought coherently. But this is to re-introduce the possibility of a radical discrepancy between the coherence of thinking and the way the world is in-itself – any irrational hypothesis about the latter become possible and strong correlationism looms once again.

Whatever the shortcomings attendant upon their lack of formal stringency, these conjectures seem to point to a fundamental dilemma confronting Meillassoux's project. If he accepts – as we believe he must – that thinking is part of being as the second fundamental speculative implication of scientific rationality after that of diachronicity, then the universal scope of the principle of factuality generates a paradox whereby it seems to contradict itself: the claim that everything is necessarily contingent is only true if this thought exists necessarily. Alternatively, if Meillassoux decides to uphold the exceptional status of thinking vis-à-vis being then he seems to compromise his insistence on diachronicity, for the intelligible reality of contingent being is rendered dependent upon the ideal coherence of the principle of factuality. Indeed, the appeal to intellectual intuition in the formulation of the principle already seems to assume some sort of reciprocity between thinking and being

As one might expect, both these criticisms – *viz.*, that intellectual intuition reestablishes a correlation between thought and being and that the principle of factuality engenders a paradox – have elicited typically acute responses from Meillassoux. In a personal communication, Meillassoux has explained why he believes he can parry both objections. For Meillassoux, the principle of factuality is designed to satisfy two requirements. First, the fundamental *rationalist* requirement that reality be perfectly amenable to conceptual comprehension. This is a rebuttal of the prototypical religious notion that existence harbors some sort of transcendent mystery forever refractory to intellection. Second, the basic *materialist* requirement that being, though perfectly intelligible, remain irreducible to thought. Meillassoux insists that the claim that everything that is is necessarily contingent satisfies both criteria. In his own words:

> Being is thought without-remainder insofar as it is without-reason; and the being that is thought in this way is conceived as exceeding thought on all sides because it shows itself to be capable of producing and destroying thought as well as every other sort of entity. As a factual act produced by an equally factual thinking being, the intellectual intuition of facticity is perfectly susceptible to destruction, but not that which, albeit only for an instant, it will have thought as the eternal truth which legitimates its name, *viz.*, that it is itself perishable just like everything else that exists. […] Thus, it is on account of its capacity for a-rational emergence that being exceeds on all sides whatever thought is able to describe of its factual production; nevertheless, it contains nothing unfathomable for thought because being's excess over thought just indicates that reason is forever absent from being, not some eternally enigmatic power.[16]

These remarks already prefigure Meillassoux's recusal of the second objection, *viz.*, that if applied to itself, the principle of factuality becomes contradictory. Meillassoux maintains that the paradox can be averted by carefully distinguishing the referent of the principle from its (factual) existence. Thus, though the latter is indeed contingent, and hence as liable to be as not to be, the former is strictly necessary, and indeed it is the eternal necessity of the principle's referent that guarantees the perpetual contingency of the principle's existence:

---

[16] Personal Communication, 9/8/2006.

> One may then say that the principle as something that is *thought* in reality is factual, and hence contingent. But what is not contingent is the referent of this principle; *viz*., facticity as such insofar as it is necessary. And it is because this facticity is necessary that the principle, insofar as it is – in fact – proffered and insofar as it will be or will have been thought by some singular entity – no matter when or under what circumstances – it is for this reason that the principle will always be true the moment it is posited or thought. What is contingent is that the principle, as a meaningful statement, is actually thought; but what is not contingent is that it is true insofar as it is – as a matter of fact – thought in a time and place – no matter when or where. Consequently there is no paradox so long as the principle's domain of application is precisely restricted to entities in their being.[17]

The crucial operative distinction here is that between the necessity of contingency *qua* referent of thought and the contingency of the (factual) existence of the thought that everything is necessarily contingent. The question then is: How does Meillassoux propose to account for this separation between the contingent existence of thought and the necessary existence of its referent? Clearly, this separation is intended to safeguard the coherence of the principle, as well as the materialist primacy of the real over the ideal, by ensuring a strict differentiation between thought and reality. But given that, for Meillassoux, thought's purchase on reality is guaranteed by intellectual intuition, it follows that it must also be the latter which accounts for this distinction between thought and referent. Accordingly, it would seem that it is in and through the intellectual intuition of absolute contingency that the contingency of the thought is separated from the necessity of its referent. Everything then hinges on how Meillassoux understands the term 'intellectual intuition'.

---

[17] *Ibid.*

Clearly, he cannot be using the term in its Kantian acceptation, since, for Kant, intellectual intuition actively create its own object, unlike sensible intuition, which passively receives an independently existing object. According to Kant, only the intuitive understanding of an 'archetypical' intellect (*intellectus archetypus*) unburdened by sensibility – such as God's – possesses this power to produce its object; for our discursive understanding, mediated as it is by sensibility, it is the synthesis of concept and intuition which yields the cognitive relation between thought and its object. Meillassoux clearly rejects Kant's representationalist account of the relation between mind and world, just as he must refuse phenomenology's appeal to an intentional correlation between thought and referent. Yet it is far from evident what plausible theory of intellectual intuition could simultaneously ensure the scission between the contingency of thought and the necessity of its referent – which Meillassoux takes to be sufficient to stave off contradiction – while circumventing representational and intentional correlation as well as abjuring the archetypical intellect's production of its object (since the claim that intellection creates its object is clearly incompatible with any commitment to materialism). Though Meillassoux insists that the paradox of absolute contingency can be obviated by restricting the principle's domain of reference to 'entities in their being', he does not explain how he proposes to enforce this rigid demarcation between the principle's contingently effectuated *intension* and what he deems to be its 'eternally' necessary *extension.*

'Reference', of course, is intimately related to 'truth', but though Meillassoux claims that the truth of the principle is guaranteed by its ontological referent, this connection is anything but semantically transparent, since the extension of the expression 'absolute contingency' is no more perspicuous than that of the term 'being'. The customary prerequisite for realist conceptions of truth is an extra-theoretical account of the relation between intension and extension, but Meillassoux's attempt to construe the latter in terms of intellectual intuition makes it exceedingly difficult to see how it could ever be anything other than intra-theoretical.[18] Indeed, it is unclear how the referent 'absolute contingency' could ever be rendered intelligible in anything other than a purely conceptual register. Consequently, Meillassoux presents us with a case in which the determination of extension, or 'truth', remains entirely dependent upon a conceptually stipulated intension, or 'sense' – the referent 'absolute contingency' is exclusively determined by the sense of the contingently existing thought 'everything that is, is absolutely contingent'. But if the only way to ensure the separation between the (contingently existing) ideality of meaning and the (necessarily existing) reality of the referent is by making conceptuality constitutive of objectivity, then the absolutization of the non-correlational referent is won at the price of an absolutization of conceptual sense which violates the materialist requirement that being not be reducible to thought. Far from reconciling rationalism with materialism, the principle of factuality, at least in this version, continues to subordinate extra-conceptual reality to a concept of absolute contingency.

---

[18] *Cf.* Hilary Putnam, 'The Meaning of 'Meaning'' in *Mind, Language, and Reality: Philosophical Papers* Volume 2 (Cambridge: Cambridge University Press, 1975), 236.

Although Meillassoux's speculative overcoming of correlationism strives to deploy the latter's strongest weapons against it – as we saw with the principle of factuality itself – the distinction between the real and the ideal is part of the correlationist legacy which cannot be mobilized against it without first undergoing decontamination. For correlationism secures the transcendental divide between the real and the ideal only at the cost of turning being into the correlate of thought. Meillassoux is right to insist that it is necessary to pass through correlationism in order to overcome it, and in this regard we should follow his recommendation and find a way of deploying the distinction between real and ideal against correlationism itself. But precisely here a fundamental speculative problem reveals itself, namely: Can we think the diachronic disjunction between real and ideal while obviating any recourse to a transcendental divide between thinking and being?

Potentiality and Virtuality[1]

Quentin Meillassoux

1. A DISSOLVED ONTOLOGICAL PROBLEM

'Hume's problem', that is to say, the problem of the grounding of causal connection, has known the fate of most ontological problems: a progressive abandonment, legitimated by the persistent failure that various attempts at resolving it have met with. Thus Nelson Goodman, in a famous article[2] can affirm without hesitation the 'dissolution of the old problem of induction'. This dissolution, as laid out by Goodman, concerns the ontological character of Hume's problem, which obliges whoever accepts its terms to accept the necessity of a principle of the uniformity of nature, a principle the proof of whose existence will then be attempted. The argument

---

[1] Originally published as 'Potentialité et virtualité' in *Failles* no. 2 (Spring 2006).

[2] N. Goodman, N, *Fact, Fiction and Forecast* (Camb., MA: Harvard University Press, 1983 [4th. Ed.]), Ch. 3.

which, in Goodman, concludes with the dissolution of the 'old problem of induction' is as follows:

- The problem of induction as formulated by Hume consists fundamentally in asking how we can justify that the future should resemble the past.
- Goodman, following Hume, fully affirms that we simply cannot do so: this justification is impossible by rational means.
- We must therefore abandon this undecidable problem, in order to pose it under another form, in which it will once again become amenable to treatment, namely: which rule, or set of rules, do we apply when we – and above all, when scientists – make inductive inferences? The question therefore no longer consists in proving the resemblance of the future and the past, but in describing an existing practice (induction) so as to try to extract its implicit rules. The dissolution of the ontological problem is thus accompanied by its methodological and epistemological reformulation: instead of vainly trying to prove the necessity of observable constants, we must set ourselves the task of describing the precise rules which scientists apply, usually implicitly, when they present us with inductive inferences. Thus Goodman can consider Hume's solution of his own problem – that our belief in induction derives from habit and not from consequent reasoning – correct in principle, however partial it might be: because in passing from the insoluble problem of the justification of an ontological principle to that of an effective genesis in the mind, Hume had already registered the intuition that the only adequate treatment of such a problem would consist

in describing the effective process by which we draw inductions, not in seeking a metaphysical foundation for it. Consequently, Goodman proposes to follow such a path, forsaking however the psychological description of the spontaneous behaviour of individuals to which Hume confined himself (*viz.*, that we believe in our inductive inferences because of our faculty of believing more and more intensely in recurrent phenomena) in favour of a description of the practices and procedures of the scientific community.

In short, the dissolution of the problem of induction comprises two phases:

- A negative phase of abandonment of the supposedly insoluble problem.
- A phase of recomposition or reformulation of the problem, which consists in passing from an ontological question – is there something like a necessary connection between events? – to a question which evacuates all ontological problems, applying itself instead to the description of effective practices by which scientific inductions are carried out.

2. PRECIPITATION OF THE PROBLEM

My proposal is as follows: to contest the dissolution of Hume's problem, that is to say the abandonment of the ontological formulation of the problem, by maintaining that the latter can be resolved in a way which has, so it would seem, been hitherto neglected. I will intervene, then, only in the first stage of dissolutory reasoning – which is presupposed by the second (the recomposition of new problems): the proposition that the ontological problem of induction must be abandoned, since it is insoluble.

To open anew the ontological problem of the necessity of laws, we must distinguish this problem from that posed by Hume, which is in fact a *particular, already oriented,* formulation of this problem taken in its full generality.

Hume's formulation of the problem is as follows: Can we prove the effective necessity of the connections observed between successive events? The presupposition made both by Hume and by Goodman is that, if we cannot, then *any* ontological treatment of what is called real necessity (that is to say, of the necessity of laws, as opposed to so-called logical necessity) is consigned to failure, and consequently must be abandoned. I believe that it is possible at once to accept the Hume-Goodman verdict of failure, and yet to dispute that it follows that every ontological approach to the problem is thereby disqualified. For the ontological question of real necessity, formulated in its full generality, is not married to the Humean formulation, but rather can be formulated as follows: Can a conclusive argument be made for the necessity *or the absence of necessity* of observable constants? Or, once again: is there any way to justify either the claim that the future must resemble the past, *or* the claim that the future might *not* resemble the past? In the latter case, it is a question of establishing, not that the observable laws must change in the future, but that it is contingent that they should remain identical. This perspective must be distinguished from any thesis affirming the necessity of the changing of laws – for such a thesis would be a variant of the solution envisaged by Hume: this changing of laws, precisely in so far as it is necessary, would suppose yet another law, in a higher sense – a law, itself immutable, regulating the future changes of current constants. Thus it would lead straight back to the idea of a uniformity of nature, simply pushing it back one level.

On the contrary, the ontological approach I speak of would consist in affirming that it is possible rationally to envisage that the constants could effectively change *for no reason whatsoever*, and thus with no necessity whatsoever; which, as I will insist, leads us to envisage a contingency so radical that it would incorporate all conceivable futures of the present laws, *including that consisting in the absence of their modification.* It is thus a question of justifying the effective existence of a radical contingency not only of events submitted to laws, but of laws themselves, reduced to factical constants, themselves submitted to the eventuality of an ultimately chaotic becoming – that is to say, a becoming governed by no necessity whatsoever.

Let us be sure to grasp the significance of such a position, and what it involves. The problem of induction, as soon as it is formulated as the problem of the effective necessity of laws, issues in an avowal of the defeat of reason, because nothing contradictory can be detected in the contrary hypothesis of a changing of constants. For reason does not seem to be capable of prohibiting *a priori* that which goes against the purely logical necessity of non-contradiction. But in that case, a world governed by the imperatives of reason, would be governed only by such logical imperatives. Now, this would mean that anything non-contradictory *could* (but not *must*) come to pass, implying precisely the *refusal* of all causal necessity: for causality, on the contrary, asserts that amongst different, equally conceivable events certain of them must come to pass rather than others. This being so, we would indeed have to agree that *in a rational world everything would be devoid of any reason to be as it is*. A world which was entirely governed by logic, would in fact be governed *only* by logic, and consequently would be a world where nothing has a reason to be as it is rather than otherwise, since nothing contradictory can be perceived in the possibility of such a being-otherwise. Every determination in this world would therefore be susceptible to modification: but no ultimate reason could be given for such modifications, since in that case a prior cause would have to be supposed, which it would not be possible to legitimate in preference to another, equally thinkable. But what would such a world be? To speak in Leibnizian terms, it would be world *emancipated from the Principle of Sufficient Reason* – a world discharged of that principle according to which everything must have a reason to be as it is rather than otherwise: a world in which the logical exigency of consistency would remain, but not the metaphysical exigency of persistence.

Hume's discovery, according to our account, is thus that *an entirely rational world would be by that very token entirely chaotic*: such a world is one from which the irrational belief in the necessity of laws has been extirpated, since the latter is opposed in its very content to what constitutes the essence of rationality. If, contrary to our hypothesis, one were to *supplement* logical necessity with real necessity, if one were to doubly limit the possible both by non-contradiction and by actual constants, one would then create an artificial riddle irresoluble by reason, since such an hypothesis would amount to the explicit, wholesale fabrication of a necessity foreign to all logic. *The Principle of Sufficient Reason is thus another name for the irrational* – and the refusal of this principle, far from being a way of doing away with reason, is in my opinion the very condition of its philosophical reactualisation. The refusal of the Principle of Sufficient Reason is not the refusal of reason, but the discovery of the power of chaos harboured by its fundamental principle (non-contradiction), as soon as the latter is no longer supplemented by anything else – the very expression 'rational chaos' from that moment on becoming a pleonasm.

But such a point of view also provides us with a new understanding of the 'end of metaphysics'. If metaphysics is essentially linked to the postulation – whether explicit or not – of the Principle of Sufficient Reason, the former cannot be understood, in Heideggerian fashion, as the final accomplishment of reason, but as the final accomplishment of real necessity, or again of what I call the reification of rational necessity. From this point of view, I understand by metaphysics, any postulation of a real necessity: so that it would constitute a metaphysical postulation that all or certain given determinate situations in this world are necessary (a determination being definable as a trait capable of differentiating one situation from another, equally thinkable situation). A metaphysics would thus affirm that it is possible, and moreover that it is the very task of reason, to establish why things must be thus rather than otherwise (why some particular individuals, law(s), God(s), *etc.*, rather than other individuals, laws, etc.)

3. ONTOLOGICAL REFORMULATION

The question now is as follows: in accepting the possibility of a change in natural constants, have we not suppressed the problem of induction itself? In other words: once the idea of a necessary constancy of laws is refused, can Hume's question still be posed in the form of a *problem* to be resolved, and more precisely as an ontological problem? It certainly can.

I would affirm that, indeed, there is no reason for phenomenal constants to be constant. I maintain, then, that these laws could change. One thereby circumvents what, in induction, usually gives rise to the problem: the proof, on the basis of past experience, of the future constancy of laws. But one encounters another difficulty, which appears at least as redoubtable: if laws have no reason to be constant, *why do they not change at each and every instant*? If a law is what it is purely contingently, it could change at any moment. The persistence of the laws of the universe seems consequently to break all laws of probability: for if the laws are effectively contingent, it seems that they must frequently manifest such contingency. If the duration of laws does not rest upon any necessity, it must be a function of successive 'dice rolls', falling each time in favour of their continuation or their abolition. From this point of view, their manifest perenniality becomes a probabilistic aberration – and it is precisely because we never observe such modifications that such an hypothesis has seemed, to those who tackled the problem of induction, too absurd to be seriously envisaged.

Consequently, the strategy of the reactualision of the ontological problem of induction will be as follows:

1) We affirm that there exists an ontological path which has not been seriously explored: that consisting in establishing, not the uniformity of nature, but the contrary possibility of every constant being submitted to change in the same way as any factual event in this world – and this without any superior reason presiding over such changes.

2) We maintain that the refusal to envisage such an option for the resolution of the problem is based on an implicit probabilistic argument consisting in affirming that every contingency of laws must manifest itself in experience; which amounts to identifying the contingency of laws with their frequent modification.

3) Thereby, we have at our disposal the means to reformulate Hume's problem without abandoning the ontological perspective in favour of the epistemic perspective largely dominant today. Beginning to resolve the problem of induction comes down to *delegitimating the probabilistic reasoning at the origin of the refusal of the contingency of laws*. More precisely, it is a matter of showing what is fallacious in the inference from the contingency of laws to the frequency (and thus the observability) of their changing. This amounts to refusing the application of probability to the contingency of laws, thereby producing *a valuable conceptual distinction* between contingency understood in this radical sense and the usual concept of contingency conceived as chance subject to the laws of probability. Given such a distinction, it is no longer legitimate to maintain that the phenomenal stability of laws compels us to suppose their necessity. This permits us to demonstrate that, without serious consequence, real necessity can be left behind, and with it the various

supposedly insoluble enigmas it occasioned.

In short, *Hume's problem becomes the problem of the difference between chance and contingency*.

4. PRINCIPLE OF THE DISTINCTION CHANCE/CONTINGENCY

To demonstrate why laws, if they can change, have not done so frequently, thus comes down to disqualifying the legitimacy of probabilistic reasoning when the latter is applied to the laws of nature themselves, rather than to events subject to those laws. Here is how such a distinction can, in my opinion, be effectively made: to apply a probabilistic chain of reasoning to a particular phenomenon supposes as given the universe of possible cases in which the numerical calculation can take place. Such a set of cases, for example, is given to a supposedly symmetrical and homogeneous object, a die or a coin. If the die or the coin to which such a calculative procedure is applied always falls on the same face, one concludes by affirming that it has become highly improbable that this phenomenon is truly contingent: the coin or die is most likely loaded, that is to say, it obeys a law – for example the law of gravitation applied to the ball of lead hidden within. And an analogous chain of reasoning is applied in favour of the necessity of laws: identifying the laws with the different faces of a universal Die – faces representing the set of possible worlds – it is said, as in the precedent case, that if these laws are contingent, we would have been present at the frequent changing of the 'face'; that is to say, the physical world would have changed frequently. Since the 'result' is, on the contrary, always the same, the result must be 'loaded' by the presence of some hidden necessity, at the origin of the constancy of observable laws. In short, we begin by giving ourselves a set of possible cases, each one representing a conceivable world having as much chance as the others of being chosen in the end, and conclude from this that it is infinitely improbable that our own universe should constantly be drawn by chance from such a set, unless a hidden necessity presided secretly over the result.[3]

Now, if this reasoning cannot be justified, it is because there does not truly exist any means to construct a set of possible universes within which the notion of probability could still be employed. The only two means for determining a universe of cases are recourse to experience, or recourse to a mathematical construction capable of justifying unaided the cardinality (the 'size') of the set of possible worlds. Now, both of these paths are equally blocked here. As for the empirical approach, obviously no-one – unless perhaps Leibniz's God – has ever been at leisure to survey the entire set of possible worlds. But the theoretical approach is equally impossible: for what would be attempted here would be to affirm that there is an infinity of possible worlds, that is to say of logically

---

[3] It was through reading Jean-René Vernes' *Critique de la raison aléatoire* (Paris: Aubier 1981) that I first grasped the probabilistic nature of the belief in the necessity of laws. Vernes proposes to prove by such an argument the existence of a reality external to the representations of the Cogito, since it alone would be capable of giving a reason for a continuity of experience which cannot be established through thought alone.

As I have remarked elsewhere, I believe that an equally *mathematical* – more specifically, probabilistic – argument underlies the Kantian transendental deduction of the categories in the *Critique of Pure Reason.* Kant's argument – as elaborate as it might be in its detail – seems to me to be in perfect continuity with what we might call the argument of 'good sense' against the contingency of natural laws. I argue that Kant's deduction consists simply in exacerbating the thinkable worlds, which could only reinforce the conviction that the constancy of just one of them is extraordinarily improbable. But it is precisely on this point that the unacceptable postulate of our 'probabilist sophism' hinges, for I ask then: of which infinity are we speaking here? We know, since Cantor, that infinities are multiple, that is to say, are of different cardinalities – more or less 'large', like the discrete and continuous infinities – and above all that these infinities constitute a multiplicity it is impossible to foreclose, since a set of all sets cannot be supposed without contradiction. The Cantorian revolution consists in having demonstrated that infinities can be differentiated, that is, that one can think the equality or inequality of two infinities: two infinite sets are equal when there exists between them a biunivocal correspondence, that is, a bijective function which makes each element of the first correspond with one, and only one, of the other. They are unequal if such a correspondence does not exist. Further still, it is possible to demonstrate that, whatever infinity is considered, *an infinity of superior cardinality* (a 'larger' infinity) *necessarily exists*. One need only construct (something that is always possible) the set of the parts of this infinity. From this perspective, it becomes impossible to think a last

---

'probabilistic sophism' critiqued in the present article, to the point where the following is argued: if laws were contingent, they would change so frequently, so frenetically, that we would never be able to grasp anything whatsoever, because none of the conditions for the stable representation of objects would ever obtain. In short, if causal connection were contingent, we would know it so well that we would no longer know anything. As can be seen, this argument can only pass from the notion of contingency to the notion of frequency given the presupposition that it is extraordinarily *improbable* that the laws should remain constant rather than being modified in every conceivable way at every moment. ('Temps et surgissement ex nihilo', presentation in the seminar series *Positions et arguments* at the École Normale Supérieure, April 2006. See http://www.diffusion.ens.fr/index.php?res=conf&idconf=701).

infinity that no other could exceed.[4]

But in that case, since there is no reason, whether empirical or theoretical, to choose one infinity rather than another, and since we can no longer rely on reason to constitute an absolute totality of all possible cases, and since we cannot give any particular reason upon which to ground the existence of such a universe of cases, we cannot legitimately construct any set within which the foregoing probabilistic reasoning could make sense. This then means that it is indeed incorrect to infer from the contingency of laws the necessary frequency of their changing. So it is not absurd to suppose that the current constants might remain the same whilst being devoid of necessity, since the notion of possible change – and even chaotic change, change devoid of all reason – can be separated from that of frequent change: *laws which are contingent, but stable beyond all probability, thereby become conceivable*.

We must add, however, that there are two possible versions of such a strategy of resolution:

---

[4] The set of parts of a set is the set of subsets of that set, that is to say the set of all possible regroupings of its elements. Take, for example, the finite set comprising three elements: (1, 2, 3). The set of its parts comprises (apart from the empty set, which is a part of every set): (1), (2) and (3) (the 'minimal' parts composed from its elements alone), (1,2), (1,3), (2,3), and (1,2,3) – this last part (1,2,3) being considered as the maximal part of the set, identical to it. It is clear that this second set is larger (possesses more elements) than the first. It can be proved that this is always the case, the case of an infinite set included. It is thus possible, for every infinite set, to construct a set of superior cardinality: the infinity which comprises the set of its parts. But this construction can equally be carried out on this new infinity, and so on indefinitely. For a clear introduction to axiomatic set theory, see Laurent Schwarz, *Analyse* I (Paris:Hermann,1991). The reference work on the philosophical importance of set-theory remains for me Alain Badiou's *L'être et l'événement* (Paris: Seuil, 1988), translated by Oliver Feltham as *Being and Event* (London: Continuum, 2006).

- A 'weak version' – a critical version, let us say – that would consist in limiting the application of aleatory reasoning to cases already submitted to laws (to observable events governed by the constants determining the universe where the calculation is carried out) but not to the laws themselves. Thereby, one would not be able to demonstrate positively the absence of real necessity, but only that its presupposition is of no use in giving an account of the stability of the world. One would content oneself with emphasising the theoretical possibility of contingent but indefinitely stable laws, by disqualifying the probabilist reasoning which concludes that such an hypothesis is aberrant. The two terms of the alternative – real necessity, or the contingency of laws – being equally non-demonstrable, the heuristic advantage of choosing the second hypothesis is invoked, by showing that it would obviate certain classical speculative enigmas linked to the unchallenged belief in the uniformity of nature.
- A 'strong', that is to say, speculative, version of the response to Hume's problem, would consist in maintaining positively the contingency of laws. Such an approach would incorporate the assets of the argument from heuristics in the above approach to its profit, but would go further, claiming to effectuate the consequences of the Cantorian intotalisation.

My overall project is to not limit myself to the critico-heuristic path, but to reactivate a speculative path (claiming to speak for the things themselves, despite the critical proscription), without ever reactivating metaphysics (that is to say, the absolutisation of a real necessity). Since it is impossible to give the full details of such an approach here, I will content myself with isolating the principal aspects of the critico-heuristic path.[5]

5. ONTOLOGICAL CONSEQUENCES OF THE NON-ALL.

We will adopt the following perspective: we suppose the ontological effectivity of the intotalisation of cases, in order to draw the consequences of such an hypothesis upon the notion of becoming, and to envisage its speculative advantages over the inverse hypothesis of the pertinence of real necessity.

In order to do this, let us reconsider the notion of the contingency of laws by restricting the notion of law to what constitutes its minimal condition, if not its complete definition: namely a determinate set, finite or infinite, of possible cases – a law, deterministic or aleatory, always comes down to a specific set of indexed cases.[6] We will try to determine the sense of a becoming within which laws themselves would be contingent, by comparing such a conception with the traditional vision according to which becoming is only thinkable as governed by immutable laws.

---

[5] For further indications as to the exigency of this reactivation, see my *Après la Finitude: Essai sur la nécessité de la contingence* (Paris:Seuil, 2006). I lay out the possible principles of the speculative approach in a forthcoming paper to be published by Éditions Ellipses (proceedings of Francis Wolff's Nanterre 2001 seminar series *Positions et arguments*).

[6] I obviously do not claim that a law can be reduced to a set of possible cases, but that a condition of every law consists in the supposition that a determinate set of possible 'reals' can be discriminated amongst mere logical possibilities. I am thus adopting an argument *a minima*: I challenge the idea that one can even consider that there exists a set such that it would permit make of laws themselves cases of a Universe of laws (of a set of possible worlds determined by different laws). Since even this minimal condition of every law which is the definition of a determinate set of cases is not respected, this disqualifies *a fortiori* every attempt to think such laws in the same way as an event submitted to a law. To review the most important contemporary discussions of the notion of law, *cf.* A. Barberousse, P. Ludwig, M. Kistler, *La Philosophie des sciences au XXè siècle* (Paris: Flammarion, 2000), Chs. 4 and 5.

Every postulation of a legality, whether determinist or aleatory, identifies the world with a universe of possible cases indexable in principle, that is to say, pre-existing their ultimate discovery, and thereby constituting the potentialities of that universe. Whether a supposed law is considered probabilistic or deterministic, it posits in any case a pre-given set of possible cases which no becoming is supposed to modify. The affirmation of a fundamental hazard governing becoming thus does not challenge, but on the contrary presupposes, the essential fixity of such a becoming, since chance can only operate on the presupposition of a universe of cases determined once and for all. Chance allows time the possibility of a 'caged freedom', that is to say the possibility of the advent without reason of one of those cases permitted by the initial universe; but not the freedom of extracting itself from such a universe to bring forth cases which do not belong to the set thus defined. One cannot, within the aleatory vision of the world, deduce in univocal fashion the succession of events permitted by the law, but one can in principle *index* these events in their totality – even if, in fact, their apparent infinity prohibits for all time the definitive foreclosure of their recollection. In our terminology, such a belief in the aleatory legality of the world would constitute a *metaphysics of chance*, in so far as chance supposes the postulation of a law which would prescribe the fixed set of events within which time finds itself free to oscillate without any determined order. The belief in chance is inevitably a metaphysical belief, since it incorporates the belief in the factual necessity of determinate probabilistic laws, which it is no longer possible to account for except via the necessity of supposed deterministic laws.

In the guise of a radical evolution, it seems that since the Greeks, one conception, and one only, of becoming, has always imposed itself upon us: time is only the actualisation of an eternal set of possibles, the actualisation of Ideal Cases, themselves inaccessible to becoming – this latter's only 'power' (or rather 'impotence') being that of distributing them in a disordered manner. If modernity is traditionally envisaged, as in Koyré's expression, as the passage from the closed world to the infinite universe, it remains no less true that modernity does not break with Greek metaphysics on one essential point: finite or infinite, the world remains governed by the law – that is, by the All, whose essential signification consists in the subordination of time to a set of possibles which it can only effectuate, but not modify.

Now, it is such a decision, common to the Greeks and to the moderns, from which we believe to have extracted ourselves, *by detotalising the possible*, and as a result liberating time from all legal subordination. In supposing the ontological legitimacy of the Cantorian conception of the infinite, we distinguish the infinite from the All, since the infinity of the possible cannot be equated with its exhaustion (every infinite set has a determinate cardinality, which another infinity is capable of exceeding). From this decision results the possibility of clearly distinguishing between the notions of contingency and chance, and indeed between the notions of potentiality and virtuality. *Potentialities* are the non-actualised cases of an indexed set of possibilities under the condition of a given law (whether aleatory or not). *Chance* is every actualisation of a potentiality for which there is no univocal instance of determination on the basis of the initial given conditions. Therefore I will call *contingency* the property of an indexed set of cases (not of a case belonging to an indexed set) of not itself being a case of a set of sets of cases; and *virtuality* the property of every set of cases of emerging within a becoming which is not dominated by any pre-constituted totality of possibles.

In short: I posit that the law can be related to a universe of determinate cases; I posit that there is no Universe of universes of cases; I posit that time can bring forth any non-contradictory set of possibilities. As a result, I accord to time the capacity to bring forth new laws which were not 'potentially' contained in some fixed set of possibles; I accord to time the capacity to bring forth situations *which were not at all contained in precedent situations*: of creating new cases, rather than merely actualising potentialities that eternally pre-exist their fulguration. If we maintain that becoming is not only capable of bringing forth cases on the basis of a pre-given universe of cases, we must then understand that it follows that such cases irrupt, properly speaking, *from nothing*, since no structure contains them as eternal potentialities before their emergence: *we thus make irruption* ex nihilo *the very concept of a temporality delivered to its pure immanence*.

This merits further explanation. If one thinks becoming in the mode of a temporality which does not supervene upon any determinate law, that is to say, any fixed set of possibles, and if one makes of laws themselves temporal events, without subordinating the possible passage from one law to another to a higher-level law which would determine its modalities, time thus conceived is not governed by any non-temporal principle – it is delivered to the pure immanance of its chaos, its illegality. But this is just another way to emphasise – something Hume was the first to maintain – that from a determinate situation, one can never infer *a priori* the ensuing situation, an indefinite multiplicity of different futures being envisageable without contradiction. Grafting the Humean thesis onto that of Cantorian intotality, we see emerging a time capable of bringing forth, outside all necessity and all probability, situations which are not at all pre-contained in their precedents, since according to such a perspective, the present is never pregnant with the future. The paradigmatic example of such an emergence, to which we shall return, is obviously that of the appearance of a life furnished with sensibility directly from a matter within which one cannot, short of sheer fantasy, foresee the germs of this sensibility, an apparition which can only be thought as an supplement irreducible to the conditions of its advent.

As it emerges according to the model of intotality, time might either, for no reason, maintain a universe of cases, a configuration of natural laws, within which it is possible to index a determinate set of recurrent situations constituting its 'potentialities' – or might, equally without reason, cancel the old universe, or supplement it with a universe of cases which were not at all pre-contained in the precedents, nor in any other Substrate wherein the possibilities of being would be ranged for all eternity. We must thus grasp the fact that the inexistence of a pre-constituted All of possibles makes of the emergence of a possible anticipated by nothing in the preceding situation, the very manifestation of a time underwritten by no superior order: every emergence of a supplement irreducible to its premises, far from manifesting the intervention of a transcendent order in rational becoming, becomes the rigorous inverse: a manifestation of a becoming which nothing transcends.[7]

Thus, for 'potentialism' (the doctrine that sees in each possibility only a potentiality), time can only be the medium by which what was already a possible case, becomes a real case. Time, then, is the throw with which the die offers us one of its faces: but in order for the faces to be presented to us, it must be the case that they pre-existed the throw. The throw manifests the faces, but does not engrave them. According to our perspective, on the contrary, time is not the putting-in-movement of possibles, as the throw is the putting-in-movement of the faces of the die: time creates the possible at the very moment it makes it come to pass, it brings forth the possible as it does the real, it inserts itself in the very throw of the die, to bring forth a seventh case, in principle unforeseeable, which breaks with the fixity of potentialities. Time throws the die, but only to shatter it, to multiply its faces, beyond any calculus of possibilities. Actual events cease to be doubled by phantomatic possibilities which prefigure them before they occur, to be conceived instead as pure emergences, which before being are nothing, or, once again, which do not pre-exist their existence.

---

[7] To be more precise, we must say that the distinction potentiality/virtuality is gnoseological rather than ontological, in so far as it designates essentially a difference in our cognitive relation with temporality. The perpetuation of a Universe of already-known cases (the constancy of laws) itself also escapes all consideration in terms of potentiality. For if one can determine potentialities within a determinate set of possibles, the maintenance across time of a determinate law itself cannot be evaluated in tems of potentiality (one possible case in a set of others). Even if the case which comes to pass is already indexed, it is only foreseen upon condition – an unforeseeable and improbabilisable condition – of the maintenance of the old set of

In other words, the notion of virtuality, supported by the rationality of the Cantorian decision of intotalising the thinkable, makes of irruption *ex nihilo* the central concept of an immanent, non-metaphysical rationality. Immanent, in that irruption *ex nihilo* presupposes, against the usually religious vision of such a concept, that there is no principle (divine or otherwise) superior to the pure power of the chaos of becoming; non-metaphysical in that the radical rejection of all real necessity assures us of breaking with the inaugural decision of the Principle of Sufficient Reason.

The most effective way to grasp properly the sense of the thesis proposed here is perhaps, as mentioned, to subtract it from the heuristic interest. This separation can be carried out through a series of elucidations permitted by such a model – elucidations of problems generally held to be insoluble, and thus sterile.

Firstly, as we have already said, such a model permits us to dissociate the notion of the stability of the empirical world from that of real necessity. The reprise of the problem of induction sought to show that it is possible to abandon the idea of a necessary constancy of laws, without this abandonment leading to the opposite idea of a

---

possibles. Ultimately, the Universe can be identified with the factual re-emergence of the same Universe on the ground of non-totality. But the virtualising power of time, its insubordination to any superior order, lets itself be known, or is phenomenalised, when there emerges a novelty that defeats all continuity between the past and the present. *Every 'miracle' thus becomes the manifestation of the inexistence of God*, in so far as every radical rupture of the present in relation to the past becomes the manifestation of the absence of any order capable of overseeing the chaotic power of becoming.

necessarily disordered world. For the disqualification of the probabilist reasoning which implicitly founds the refusal of a contingency of laws suffices to demonstrate that the possible changing of constants of this world does not indicate their necessary continual upheaval: by affirming that the world could really submit its laws to its own becoming, one posits the concept of a contingency superior to all necessity, *one whose actualisation is therefore subject to no constraint* – and above all not that of a frequential law supposed to render more and more improbable the non-effectuation of certain possibilities. For to affirm that the changing of laws, if it *could* happen, *must* happen, is to subordinate anew the contingency of becoming to the necessity of a law, according to which every possible must eventually be actualised. An entirely chaotic world – submitting every law to the power of time – could thus in principle be phenomenally *indiscernible* from a world subject to necessary laws, since a world capable of everything must *also* be able *not* to effect all that it is capable of. Thus it becomes possible to justify the postulate of all natural science – namely the reproducibility of experimental procedures, supposing a general stability of phenomena – whilst assuming the effective absence of a principle of uniformity of nature, and by the same token abandoning the canonical enigmas linked to the hypothesis of a necessity of laws. But this abandonment does not proceed, as in Goodman, from a simple refusal to think the problem, a refusal justified by its supposed insolubility: it proceeds from the conviction that one can think the contingency of constants compatibly with their manifest stability.

The critique of the probabilistic sophism given above can also be extended to its application in various analogous arguments, which generally seek to restore a certain form of finalism. I will content myself here with mentioning one example of such an extension of the critical analysis, that of anthropism.

The thesis of anthropism – more precisely, of what is known as the Strong Anthropic Principle – rests fundamentally upon the following hypothesis:[8] one imagines oneself able to vary in an arbitrary fashion the initial givens of a universe in expansion, such as the numbers which specify the fundamental laws of contemporary physics (that is to say the relations and constants involved in these laws). One is then in a position to determine the evolution of these artificial universes, and one notes, in almost all cases, that these latter are incapable of evolving towards the production of the components indispensable for the emergence of life and, *a fortiori*, of intelligence. This result, which emphasises the extreme rarity of universes capable of producing consciousness, is then presented *as deserving of astonishment* – astonishment before the remarkable coincidence of the contingent givens of our universe (contingent in so far as there is no means to deduce their determinations – they can only be observed within experience) with the extremely restrictive physical conditions presiding over the appearance of conscious life: how is it that our universe should be so precisely furnished with the necessary characteristics for our appearance, whereas these characteristics prove to be of such rarity on the level of possible universes? *Such an astonishment thus rests upon reasoning that is clearly probabilistic*, relating the number of possible universes to the number of universes capable of life. The anthropist begins by being surprised by a coincidence too strong to be imputed to chance alone, and then infers the idea of an enigmatic finality having predetermined our universe to comprise the initial constants and givens which render possible the emergence of man. Anthropism thus reactivates a classical *topos* of finalist thought: the remarking of the existence of a highly-ordered reality (inherent to the organised and thinking being) whose cause cannot reasonably be imputed to chance alone, and which consequently imposes the hypothesis of a hidden finality.

---

[8] For a definition of the various versions of the Anthropic Principle, See J.D.Barrow and F.J.Tipler, *The Anthropic Cosmological Principle* (Oxford: Oxford University Press, 1986), Introduction and Section 1.2.

Now, we can see in what way the critique of the probabilist sophism permits us to challenge such a *topos* in a new way. For such reasoning is only legitimate if we suppose the existence of a determinate set (whether finite or infinite) of possible universes, obtained through the antecedent variation of the givens and constants of the observable universe. Now, it appears that there are no legitimate means of constituting the universe of possibles within which such reasoning could make sense, since this means, once more, could be neither experimental nor simply theoretically: as soon as one frees oneself from the imperatives of experience, in the name of what principle can one limit, as the Anthropic Principle implicitly does, the set of possible worlds to those obtained solely by the linear variation of constants and variables found in the currently observable universe, and in whose name do we limit such a set of worlds to a determinate infinity? In truth, once the possible is envisaged in its generality, every totality becomes unthinkable, and with it the aleatory construction within which our astonishment finds its source. The rational attitude is not, in actual fact, to seek an explanation capable of responding to our astonishment, but to trace the inferential genealogy of the latter so as to show it to be the consequence of an application of probabilities outside the sole legitimate field of their application.

Finally, the abandonment of real necessity permits one last elucidation, this time concerning the emergence of new situations, whose qualitative content is such that it seems impossible to detect, without absurdity, its anticipated presence in anterior situations. So that the problem appears in all clarity, let us take the classical example of the emergence of life, understood here not merely as the fact of organisation but as subjective existence. From Diderot's hylozoism, to Hans Jonas' neo-finalism,[9] the same argumentative strategies are reproduced time and time again in philosophical polemics on the possibility of life emerging from inanimate matter. Since life manifestly supposes, at least at a certain degree of its evolution, the existence of a set of affective and perceptive contents, either one decides that matter already contained such subjectivity in some manner, in too weak a degree for it to be detected, or that these affections of the living being did not pre-exist in any way within matter, thus finding oneself constrained to admit their irruption *ex nihilo* from that matter – which seems to lead to the acceptance of an intervention transcending the power of nature. Either a 'continuism', a philosophy of immanence – a variant of hylozoism – which would have it that *all* matter is alive to some degree; or the belief in a transcendence exceeding the rational comprehension of natural processes. But such a division of positions can once more be called into question once irruption *ex nihilo* becomes thinkable within the very framework of an immanent temporality. We can then challenge both the necessity of the preformation of life within matter itself, and the irrationalism that typically accompanies the affirmation of a novelty irreducible to the elements of the situation within which it occurs, since such an emergence becomes, on the contrary, the correlate of the rational unthinkability of the All. The notion of virtuality permits us, then, to *reverse the signs*, making of every radical irruption the manifestation, not of a transcendent principle of becoming (a miracle, the sign of a Creator), but of a time that nothing subtends (an emergence, the sign of the non-All). We can then grasp what is signified by the impossibility of tracing a genealogy of novelties directly to a time before their emergence: not the incapacity of reason to discern hidden potentialities, but, quite on the contrary, the capacity of reason to accede to the ineffectivity of an All of potentialities which would pre-exist their emergence. In every radical novelty, time makes manifest that it does not actualise a germ of the past, but that it brings forth a virtuality which did not pre-exist in any way, in any totality inaccessible to time, its own advent.[10]

---

[9] See for example H. Jonas, *The Imperative of Responsibility* (Chicago: University of Chicago, 1985), chap. 3, 4, 3b: 'The Monist Theory of Emergence'.

We thus glimpse if all-too-briefly, the outlines of a philosophy emancipated from the Principle of Sufficient Reason, and endeavouring, in this very recommencement, to maintain the double exigency inherent to the classical form of rationalism: the ontology of that which is given to experience, and the critique of representation.

---

10. It might be objected that in the preceding arguments I tend to conflate potentialism – which makes of every possible a potentiality – and a continuism which claims to discern for every present novelty a past situation wherein all the elements of such a novelty already existed, if at a lesser degree. It will be objected that one might at once claim that the world is subject to immutable laws, and refuse the actualism of preformationism, which sees the world as a set of Russian dolls where everything is already effective before being manifest. I respond that I certainly do not conflate the two theses, but that potentialism and preformationism, having in common the refusal of virtuality, are equally incapable of thinking a pure novelty: potentialism, in particular, if it claims that sensation is a potentiality of matter which was not actualised by it before its emergence in the living, would accumulate disadvantages, since it would be constrained to combine the mystery of real necessity (matter is ruled by laws which give birth to sensitive contents under determinate conditions) and that of irruption *ex nihilo* (these contents are in no way contained in the conditions that make them emerge).

Dark Matter: Probing the Arche-Fossil

Interview with Roberto Trotta

Dr. Roberto Trotta[1] *coordinates Oxford University's* Dark Sector Initiative,[2] *an enterprise dedicated to elucidating the nature of 'dark matter' and 'dark energy'. The cross-disciplinary nature of this project – described as an intense collaborative work involving mathematics, theoretical physics, phenomenology and statistics – anticipates the problematic status of its objects. Trotta's work as a theoretical cosmologist takes place at the intersection of cosmology (the attempt to construct a coherent model and narrative of the origin and evolution of the universe), astrophysics (the description in physical terms of the objects observed in the universe), and theoretical physics (positing models of the elementary constituents of matter and their interactions). Observations of astrophysical entities are interpreted in cosmology within the framework of theoretical physics, drawing upon powerful statistical techniques to derive probabilistic inferences on the fundamental phenomena under scrutiny, even in cases where the astrophysical objects themselves are poorly understood. Equally, some of the most advanced and speculative theoretical physics finds its best (and sometimes unique) testing-ground in models of the early universe.*

Collapse interviewed Trotta at the Beecroft Institute for Particle Astrophysics and Cosmology (BIPAC) with a view to understanding how the process of determination of this field of research on the 'outer edge' of science, bounded equally by technological, probabilistic and logical constraints, brings to light the process of scientific thought, and problematises its very conceptual foundations, thus emphasising its continuities with traditionally 'philosophical' concerns.

COLLAPSE: We would like to investigate with you the general question of the status of the objects of your research. Could you describe to us how empirical observation, theoretical postulation, and the aspiration towards a coherent cosmological model interact to create this problematic object of study – 'dark matter' – and compel scientists to posit its reality?

ROBERTO TROTTA: We are interested in this 'dark matter', or 'dark sector' of the universe primarily because it enters, in an unexpected way, into our observations. Many different fundamental explanations for dark energy have been advanced, but the need for its postulation was brought forward primarily by empirical evidence; indirect, sometimes, but still empirical evidence, interpreted within the framework of a certain cosmological model.

According to the current paradigm, about 5 percent of the matter-energy of the universe is visible, and of this 5 percent only a fraction goes to form stars or planets or other heavenly bodies – the largest part is in the form of gas. 95 percent of the universe is 'dark', in one way or another: about 25 percent dark matter, 75 percent what we call dark energy.

The existence of dark matter is both predicted by fundamental models of theoretical physics, such as supersymmetry, and required by cosmological observations highlighting the problem of the ‘missing mass’ of the universe. In fact, many pieces of evidence strongly suggest that there is much more mass in the universe than the visible counterpart in the form of galaxies and clusters we can see. It is postulated that the missing mass does not interact with light, and this would explain why it is dark. But its existence is revealed by its gravitational effect on other massive bodies, for instance the distribution of galaxies in the universe, or the overall gravitational dynamics of the cosmos. This is how dark matter enters the cosmological model.

C: And what about ‘dark energy’?

RT: The case for dark energy is even more puzzling: observations of stellar explosions called supernovae indicated that the expansion of the universe is accelerating, rather than slowing down as it should under the influence of gravity if its content were in the form of ordinary matter (both visible and dark) and radiation. The accelerated expansion thus requires the presence of a new ‘substance’ with negative pressure, which would act as an ‘anti-gravity’ of sorts on cosmological scales: this is what has been dubbed ‘dark energy’. In contrast to dark matter, at the moment we do not have many fundamentally motivated models for dark energy, except perhaps Einstein’s cosmological constant – which, however, has to be inserted by hand into Einstein's equations to explain the present-day acceleration of the universe. But cosmologists are an inventive lot, and people were quick to introduce into the game new, *ad hoc* forms of energy to explain the accelerated expansion, perhaps in the form of so-called scalar fields. Fittingly, such models have been christened 'quintessence', since dark energy would be a fifth substance in the universe on top of the known four, *i.e.* photons, neutrinos, baryons (*i.e.* visible matter) and dark matter.

It's a very unsatisfactory state of things, thinking that after all this work in cosmology, forty years after cosmology was born with Penzias and Wilson, eighty years after Hubble discovered the expansion of the universe, we are stuck with this most incredible situation: that 95 percent of the universe is 'dark'. But we do believe that we have good reasons – empirical reasons – to have to go out and explain this missing mass and energy.

And so, the research programme is cross-disciplinary in the sense that it is really a field where you have the empirical observations – which I'll describe in more detail – of dark matter and dark energy. You have theoretical modelling, which is used both to interpret the observations cosmologically, and to try to give us a framework to predict further phenomena, or to explain phenomena. Then you have statistics, which is used to govern the data, to interpret them in a statistically sound way. And you have mathematics, since all these formulations, all these theories, are heavily mathematical, and we're trying to use them to derive the logical consequences of our observations. But it's really all interrelated. You can jump into this cycle at any point. You can start the cycle from, say, observations;

this gives you evidence for unexplained phenomena. At this point, you get the observation right, then you gather the statistical evidence for the phenomenon you are interested in; then you model it within a certain theoretical framework, which gives you predictions which in turn can be tested against new observations. So it's a connected chain of reasoning.

C: Historically, which observations first suggested the need to postulate dark matter?

RT: One of the first pieces of evidence for the need for dark matter goes back to the 30s and has been confirmed ever since. It's something called the 'flat rotational curves' of galaxies, and it can be explained like this. If you have a galaxy, with the visible mass of that galaxy you see there is a bulge in the middle, and then it declines – so, if it's a spiral galaxy, you have less stars in the spiral arms. Now, the further out you go in respect to the centre of the galaxy, you'd expect the velocity of the stars orbiting this galaxy to be reduced, simply because – in rather the same way as, say, Neptune goes more slowly around the Sun than the Earth does, because it's further out in the solar system – if all the gravity comes from the visible part of the galaxy, then stars which are further out should circle the galaxy more slowly than the stars that are in the centre. But observations of these velocities actually show that the velocity is constant with radius – which means either that our theory of gravity is wrong, and Newtonian-Einsteinian gravity doesn't hold on galactic scales; or that we need more matter than the visible part to keep those stars on track.

C: Evidently, in defining research programmes, a certain decision is called for: which elements of the current theoretical paradigm to preserve, and which to relinquish. For instance, in the context of physics a century ago, a decision had to be made between abandoning the Maxwellian equations regarding the constancy of the speed of light, or abandoning the Newtonian postulate of absolute simultaneity and the aether. The correct decision seems obvious to us now – perhaps it was even obvious to Einstein at the time, who seems not to have been significantly influenced by the negative outcome of the Michelson-Morley experiment. But nevertheless, it constituted a real decision, a kind of branching-point for science. Now, since you have just described the issue of these empirical observations as pressing us into a decision, let us ask: is it a straightforward matter to know which part to jettison? In the case of dark matter, why is it more cogent to hypothesise missing mass rather than a correction to the fundamental laws? Since, up to this point – despite its reassuringly substantial-sounding name – 'dark matter' has remained the name for a particular *gap* in our systematic account of the universe, then, as you say, the possibility remains that it may be, for instance, the result of a shortcoming in our understanding of gravity rather than evidence of 'missing mass'. Are both possibilities pursued in a research environment?

RT: They are pursued in parallel, to a certain extent, even though the majority of scientists would say that the dark matter hypothesis in this case would be preferred to a change in the fundamental laws of gravity, for two reasons. One reason is that we are extremely reluctant to change a theory as successful as general relativity [GR], because it accounts for phenomena on all sorts of scales, and is an extremely successful theory that has been tested to a high degree of precision. So it would seem strange – you would really have to have a compelling reason – to abandon it. That's one reason. The second reason, more from the empirical point of view, is that recent observations of the collision of clusters of galaxies – as recently as August 2006, in fact – have shown that even within the paradigm of a modified gravity, you wouldn't be able to explain these kinds of observations. So there are both reasons of theoretical prejudice – we don't want to abandon GR unless we need to; and empirical reasons – empirical facts don't seem to fit with current brands of modified gravity.

C: The flat rotational curves were the first piece of evidence, then, but others followed.

RT: Yes, we have this indirect observation from the flat rotational curves which, admittedly, relies on the fact that we have a certain model for how things spin around, certain laws of gravity – this is one piece of evidence. Then we have gravitational lensing, which is the bending of light through a gravitational field, which again, gives spectacular results, and is actually a way of highlighting the distribution of matter in the universe no matter whether it is visible or dark. This again cannot be accounted for: in the so-called ‘strong’ gravitational lensing, we see these beautiful arcs, light from background galaxies being deflected and distorted by foreground masses, and the degree of deflection cannot be accounted for merely by invoking the visible part of the foreground mass. That’s another piece of evidence. Then we’ve got this ‘fossil’ of the cosmic microwave background radiation [CMBR]. Let’s go back to the discovery of CMBR by Penzias and Wilson in 1965. Those two guys had a radio telescope set up somewhere in New Jersey, they were not looking for the background radiation, they just happened to find it. For two years they pointed their telescope to the skies, and they found the same noise everywhere, no matter where they pointed it. And they didn’t know where this noise came from. They tried to clean the telescope, they tried to get rid of this noise, they couldn’t – and eventually they got the Nobel prize for this discovery, because they’d just discovered CMBR, which is nothing else but the fact that the light emitted by the Big Bang, while travelling to us, was stretched by the expansion of the universe, and now it fills the whole universe, with a very low temperature of 3 Kelvin – so that’s minus 269° C below zero. It’s all around us. So those photons, those particles of light, come straight from the Big Bang. And they found it no matter where they looked, no matter where they pointed their telescope, which was an indication of its cosmological origin – it was not some type of local stuff, coming from a galaxy, it was really everywhere at the same time.

The CMBR leads us to attribute a global geometrical property of flatness to the universe: we have measured this huge triangle – a ‘cosmic triangle’ – that is spanned by temperature differences in the CMBR thirteen billion light years away from us. So we have this cosmic triangle: we sit at one of the vertexes, with the other two vertexes being separated by the distance between fluctuations in the temperature of the CMBR, 13 billion light years away from us. Now we have measured the angle subtended by the distant side of the triangle, *i.e.* we have measured the angle between tiny temperature differences in the CMBR on the sky. This measurement tells us that we’re living in a three-dimensional space that is analogous to a flat piece of paper, rather than a closed sphere. If I were stuck on a piece of paper like this, I would have Euclidean geometry on this piece of paper, the usual axioms of Euclidean geometry, say that parallel lines do not cross, and things like that. And that piece of paper would be a flat universe, flat, a two-dimensional universe. If we take a sphere, for instance, instead, that’s a closed universe, we’ve got the great circles which intersect, we’ve got the angles of triangles on the sphere that do not add up to 180 degrees, but rather the sum has to be larger than 180 degrees, and so that’s a closed geometry. We can measure the angles in this cosmic triangle, and they add up to 180 degrees with an accuracy better than 1 percent.

Now, if the CMBR tells us that the universe’s spatial geometry must be flat, this means that we need something else to make up what’s missing from the visible part; since the visible part, the dark matter, the dark energy, everything that’s in the universe must add up to 1, in some appropriate units, if the universe is flat. And since in these units, the visible part is only 0.05, or 5 percent, we need another 0.95 to get up to 1, so that's another piece of evidence.

C: Again, an explanatory gap: the CMBR as a whole indicates overall flatness; the observations of visible matter give you a picture which can't be reconciled with that, and then the gap between them is the place where you postulate the dark matter.

RT: Yes, but again this is only one piece of evidence, there are at least three or four different lines of evidence coming from different observations that all add up to the same numbers. So it's not just one, there are many of them, all indicating the same thing.

This dark matter is puzzling, it's not visible yet. Even though we talk about 'detection', those are indirect pieces of evidence. Although there are lines of research that are being pursued now, putting big dark matter detectors deep in caves, to shield them from other influences – the strange idea of doing astronomy underground! – under kilometres of rock to shield them from influence. You put big tanks of whatever detectors you have, and just wait for the streaming dark matter particles to give you, every now and then, a signal in your detectors when they occasionally bounce of a proton. So that would be one way to visualise them, or to detect them for real – if you give the attribute 'reality' to the data from such a sophisticated apparatus.

There would be a nice analogy here, I think, with what happened in the 1930s when Wolfgang Pauli introduced the neutrino, a new particle, to solve the puzzle of the beta-decay of atoms. They didn't know how to solve this – there was missing energy, they didn't know where the energy went. So, he wrote this famous letter to his friends at the 'Radioactive Club', saying 'Dear Radioactive Friends, today I have done a terrible thing for a theoretical physicist, that is, to introduce a new particle that nobody will ever be able to see.' But sure enough, in 1954, Cowan and Reines detected it, and later on they got the Nobel prize for it, and now there are experiments which do detect neutrinos routinely. So, dark matter might be just the same.

Such experiments are big gambles on certain predictions of a certain scientific theory: like looking for the Higgs boson, which people reckon will be found, but there is no guarantee there. You've got theoretical predictions, and the important thing is that in these theoretical predictions you have the masses, that is to say, indications of where to look for these particles. These are just numbers that are not predicted by theory, they just have to be determined experimentally, so we don't know what those numbers represent.

C: Before we go on to discuss the other lines of evidence, perhaps we can suggest a counter-example to the analogy you have just mentioned, one which is arguably closer to the case in hand than the example of Pauli's postulation of neutrinos: namely, the infamous case of the planet Vulcan. 'Vulcan' was the name given by Urbain Le Verrier in 1859 to a 'hidden' planet that allegedly perturbed Mercury's orbit, and which thus 'explained' its observed deviations from the path predicted by Newtonian physics. For over half a century astronomers attempted to prove the existence of Vulcan, and there were numerous reports which claimed to have positively ‘detected’ the hypothetical planet. Now, as we know, despite serious efforts to prove its existence over a period of some five decades, and dozens of putative observations of the planet in transit, eventually Einstein’s GR theory came along and explained the observed perturbations of Mercury as a mere by-product of the Sun’s gravitational field. So here we have a case in which a ‘missing mass’ is postulated in order to provide an explanation of certain observed anomalies, and for a long time it is the only explanation in town. However, unlike in the case of Pauli’s neutrinos, here it turns out that what was needed was not a more sophisticated means of detecting some hypothetical ‘missing matter’, but rather a suitable modification of the laws of gravity. Now, you have said that the postulation of ‘dark matter’ *might turn out to be* analogous to the case of Pauli’s postulation of neutrinos. But then, by parity of logic, ought you not to also countenance the possibility that it might turn out instead to be rather more like the case of Le Verrier’s ‘Vulcan’?

This of course brings us back to the question raised earlier of why one should regard the postulation of dark matter as more scientifically compelling than the option of modifying the laws of gravity on galactic and intergalactic scales. In response to that you suggested that, apart from a general reluctance to attempt to modify a theory as successful as GR, there were also good empirical reasons for favouring the hypothesis of ‘dark matter’, some of these relating to very recent observations of galactic collisions.

The results of the observations in question were first presented back in August 2006 in a paper by Douglas Clowe *et al.* entitled 'A Direct Empirical Proof of the Existence of Dark Matter', which announced that the observations had enabled the 'direct detection of dark matter, independent of assumptions regarding the nature of the gravitational force law.'[3] A NASA press release promptly followed proclaiming that these observations constituted 'direct proof' and 'direct evidence' of the existence of dark matter[4] and the popular media was soon awash with headlines such as 'Dark Matter Observed', 'Dark Matter Witnessed After Galactic Collision', 'Galaxy Cluster Collision Proves Existence of Dark Matter', 'Scientists Offer Proof of Dark Matter' and so on. One could surely be forgiven for assuming that what had taken place here was a veritable *experimentum crucis*, indubitably proving the existence of dark matter once and for all and definitively ruling out all rival hypotheses. It was as if dark matter had suddenly been promoted in ontological status from its previously ethereal quasi-existence as hypothetical postulate to the rank of full-fledged 'substantial' reality. And yet, without wanting in any way to diminish the significance of these observations, it seems that, from what you have just said, things are not quite so assured as we might have been led to believe, that the postulation of dark matter remains something of a high-risk gamble. Is it not at least a little premature to say that dark matter is the 'only possible explanation' of the observations, as some cosmologists have been reported in the media as having

---

3. http://arxiv.org/abs/astro-ph/0608407

4. http://www.nasa.gov/home/hqnews/2006/aug/HQ_06297_CHANDRA_Dark_Matter.html

claimed? Apart from the consideration that the postulation of a missing 95 percent of the universe represents perhaps the most audacious flouting of Ockham's razor in the history of modern science – especially when one considers that a mere tweaking of the laws of gravity might ultimately prove up to the job, even if none of the models so far constructed have done – is there not a case for saying that the kind of explanation proffered by the postulation of dark matter amounts to an example of 'explaining the obscure by the even more obscure'? To what extent is it the case that, even now, the very terms 'dark matter' and 'dark energy' serve less as names for a satisfactory explanation and more as a placeholders for possible explanations not yet envisaged?

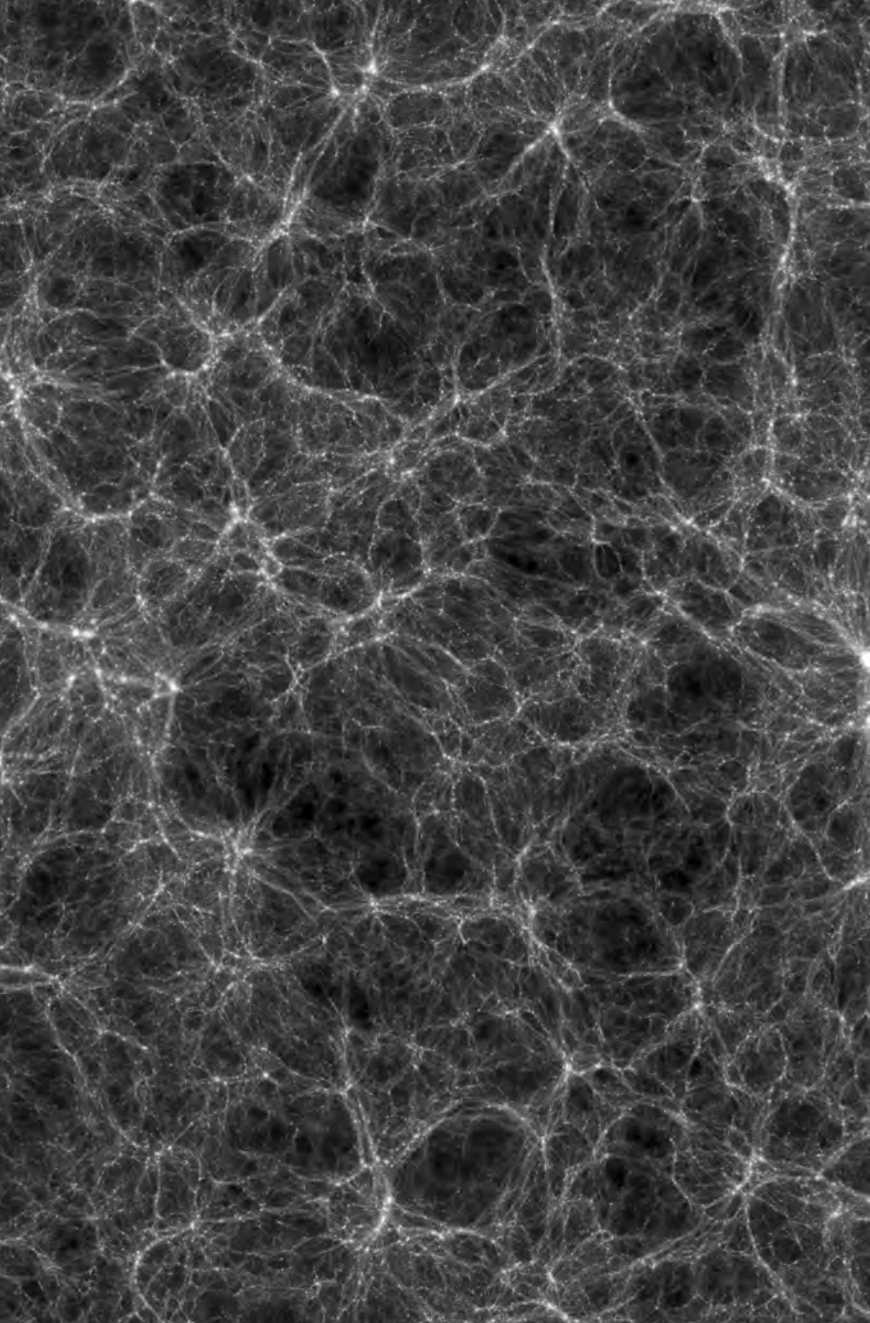
RT: As far as dark energy is concerned, yes, I would subscribe to the description you give of a placeholder for a more satisfactory explanation. In fact, one of the most pressing questions is to determine observationally whether dark energy lives on the right hand side or on the left hand side of Einstein equations. If it belongs to the left hand side – that's the side of the geometry of spacetime, where the structure of our gravity theory lives – then it's a manifestation of modified gravity of some sort, even if only in its mildest but actually quite disturbing incarnation, that's to say, Einstein's cosmological constant. If on the other hand it turns out that it belongs to the right hand side – that's where the matter-energy contents of the universe are written down – then it's really a new substance, and we have to think it over again in terms of a fundamental explanation of its physical origin.

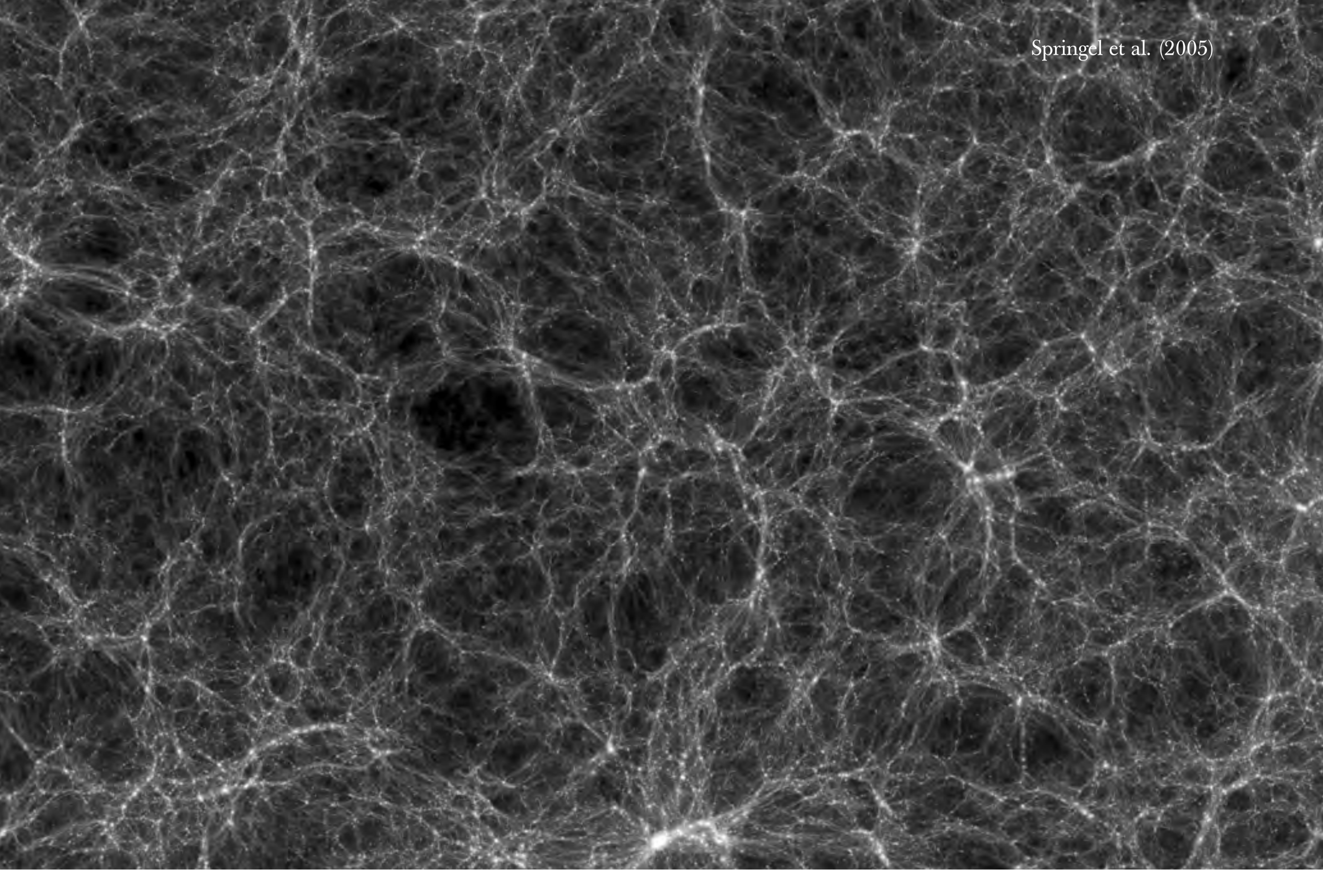
But if we are talking about dark matter, then its status is very different. I mentioned the multiple, orthogonal lines of evidence we have for it. I also briefly mentioned that we have many well-motivated candidates, usually in the form of some sort of particles beyond the Standard Model of particle physics. Now we know from other sources – for example, from the fact that neutrinos have mass – that the Standard Model cannot be complete. And we also have theories waiting in the wings to replace the Standard Model, theories that make many predictions about the existence of a plethora of new, yet-unobserved particles. For instance, in supersymmetry every known Standard Model particle acquires a so-called 'superpartner' – that's a new particle with the same properties as its Standard Model partner but with a much heavier mass. This immediately doubles the number of fundamental entities in the theory, but it seems there is really no other way around it if one wants to solve certain technical problems that we do not need to discuss now. So from the point of view of simplicity and economy, such a theory hardly ticks those boxes. But it also allows one to gain a much more complete picture of the particles and their interactions. In order to test such a theory, it remains to build a huge accelerator, smash together particles with very high energy and observe the products of the collision. Because energy is mass, if the energy achieved is large enough such collisions will transform energy into massive particles, and hopefully produce some of the heavy supersymmetric particles everybody hopes to detect. Unfortunately, the masses of the particles are just free numbers in the theory; they are not predicted, so nobody knows whether we are going to find them when the LHC is turned on later this year at CERN. People make educated guesses, but there is no guarantee. The point is that the lightest of these supersymmetric particles fits the bill for a dark matter candidate. Its properties are exactly the ones you need if you had engineered it to be the dark matter of the universe – and the thing is, you have not! The neutralino (that's the name of the particle) comes straight out of supersymmetry, and all of a sudden you realise that this could be what the cosmological dark matter is made of. So here you go, you have solved two problems at once, if only you could prove that supersymmetry exists and that the neutralino is the dark matter particle. And this is exactly what people are trying to do, both at CERN and by trying to detect dark matter particles directly.

But there is one more thing to consider, namely the fact that cosmology is fundamentally different from particle physics, or from any other brand of physics, in at least two respects. The first aspect is that cosmology is an observational science, not an experimental one. We simply cannot reproduce the universe many times, tweaking the parameters of the experiment to see whether our theory is correct. The second point is that the fundamental framework within which all observations are interpreted posits that the objects we observe are subjected to the very same laws of physics we have derived in our labs on Earth. This is an extremely strong assumption, if one keeps in mind that cosmological phenomena stretch over billions of light years in space, over the entire life of the universe in time, and over tens or hundreds of orders of magnitudes in energy. One might describe this as the ultimate scientific hubris. So in view of all this, it is important to recall that the status of the ‘substantial reality’ of cosmological objects must be understood within the limits imposed by the above considerations.

C: We’d like to come back to this question of the uniqueness of cosmology as an observational but non-experimental science a little later, but sticking for the moment with the question of the nature of the evidence for the ‘substantial reality’ of dark matter, one of the most intuitively accessible fruits of this research are the images which show the predicted distribution of dark matter in the universe [see pages 100-1]. Here we see something that to the naïve eye looks very ‘organic’, almost like a network of capillaries. Since dark matter is not visible, how are such images obtained?

RT: These images depict what we call the ‘cosmic web’ – fittingly, I think. And this is a computer simulation: this is what we think you should be able to see if you could see the dark matter distribution in the universe – those filamentary structures represent the dark matter distribution within the universe. But it’s computer-simulated: what you do is to take the initial universe, which was homogeneous, but not perfectly homogeneous – you had small initial fluctuations in density within it which were the seeds, that we still see today in the CMBR, and from which eventually those structures formed – you take this universe, put it into a supercomputer. Then you switch on gravity and you let gravity do its work. So regions that are





Springel et al. (2005)

dense will accrete matter from around them. Regions that are overdense would in time become critical overdense regions and this filamentary pattern appears during time.

So that's just a simulation. From the data we observe from gravitational lensing we are also able to extract some statistical properties of these filaments: we can quantify the filamentary structure itself, whether it's very filamentary or more sparse, more dense, and we can compare the numbers that we get out of the simulations with the observations. And this is the great game, to produce very many simulated universes with different values of parameters, to fit them to our observations, and to try to figure out which are the ones we actually observe in our universe.

C: Earlier you linked the 'puzzling' nature of dark matter with the fact that it is 'not yet visible', and indeed one of the ways in which the abstract mathematical sense given to 'matter' in contemporary physics is reconciled with our intuitive sense of materiality is through these kinds of images. There can be no doubt that images purporting to represent dark matter boast an all-important sense of immediacy which speaks to an interested general public. But is this engagement of the imagination also of significance for scientists themselves, providing a sort of milestone and an opportunity to 'zoom out' of the technical details of the research process?

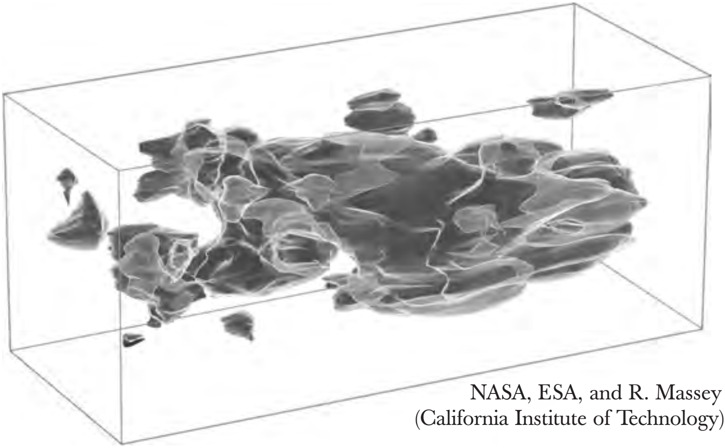
RT: Yes, I think that's a good point, in the sense that until a few years ago scientists – especially cosmologists – we didn't have those images to look at, we hardly had any of the data we have now. So in that respect having these images is a way of anchoring ourselves to the reality of those objects. Although images that you can really look at and just understand by looking at them are very rare. Most of them have to be interpreted through statistical analysis, distilling the statistical content of the image into spectra or probability distributions or whatever. Having the 'real object' – with whatever qualifications you want to give to the term 'real' here – having the real object in front of your eyes is a way of anchoring yourself to the object so as to understand it. Although, as I say, the images, as fantastic as they are for reaching out to the public, have little informative content for scientists. They must be heavily processed, they must be analysed, they must be cross-correlated, and most of those procedures do not happen in an image space; they happen in a mathematical space, a statistical space, spaces that are highly idealized and so, in a sense, also highly immaterial. So the images are just the starting point for a much more complex process that goes on behind the scenes. It's rarely just the image that gives you the answer you're looking for; it's the content of the image that's distilled through a heavily mathematical process, and that's what's interesting for the scientist. But the images are great as the first point of contact to try to convey what we get out of the image to the general public, in a more understandable way, a way which is less arid.

C: Is there a danger that they may serve to conceal – or so to speak, shortcut – uncertainties within the theoretical model? For instance, if you have an image purporting to show 'the distribution of dark matter', you're in a sense already guilty of reifying dark matter.

RT: Yes, but professional scientists, when they look at these images, are supposed to remember this. Sometimes the shortcut is taken consciously in order to make the image more 'saleable' to the public, in order to promote the field more effectively. But it's a thin line you have to tread. For example, what's described as the imaging of dark matter is actually the imaging of gravitational potentials, which has been recovered through a set of statistical techniques, transformed through false-colour images purporting to show dark matter. So yes, it is a shortcut that's consciously taken sometimes in order to make the content more directly accessible. But we should never forget that, in taking these shortcuts, we bypass our interpretation of the data we have gathered, which is done through the optic of a particular theory, and a particular narrative as to how these data have been gathered and what they mean. The point is that the very interpretation of the physical reality of the objects we observe is dependent on an underlying theory which explains them in the first place; so they're not objects we can relate to in an immediate way.

C: The essential theory-dependence or 'theory-ladenness' of observation is of course something very well-established in the philosophy of science, and it's something which has given rise to no end of philosophical debate – regarding, for example, instrumentalist versus realist interpretations of scientific statements. The very idea that knowledge is a matter of obtaining a faithful ‘copy’ of a reality-in-itself, as something knowable without theoretical mediation, is one which has lost favour in the philosophical tradition since Kant. We’d like to touch on some of these questions later, but for the moment, sticking to the point of view of a ‘naïve realism’, one might feel almost ‘cheated’ to learn that so much necessary theoretical and instrumental mediation is involved in gaining access to these objects. From the lay-person’s point of view the ‘substantial reality’ of a thing is precisely something that *ought to be* accessed in an ‘immediate’ way, without the kinds of theoretical contrivance you have described. Is there a sense in which all this necessary mediation amounts to a diminution of the reality itself, or is it rather the case that science has first to ‘constitute’ that reality in some sense – to ‘bring it into being’ almost – in order to determine it?

RT: I wouldn’t call it a diminution, I would call it an *enhancement* of reality. Perhaps an artificial enhancement to a certain extent – mediated by the theories and instrumental apparati we use – but a necessary one, for the simple reason that we simply do not have immediate access to the reality of those objects. I would even be tempted to say that the true, the most informative reality of those objects, often is *only* revealed *after* these very complex processes, and often only in a statistical sense, which is very impalpable, giving us only access to certain relations, probability distributions and so on, whose very interpretation, once again, rests on what our understanding of probability fundamentally is, rests on many assumptions on the way the world is *supposed* to behave even on a statistical level – even for



NASA, ESA, and R. Massey
(California Institute of Technology)

objects for which we don’t have a statistical realisation, such as the universe itself. So in conclusion I would say that this is an enhancement of reality that necessarily takes place in order to bring into the open underlying patterns and regularities that are not visible to the ‘naked eye’.

C: Coming back, then, to the images which purport to in some sense ‘represent’ dark matter, apart from the computer simulations – the ‘cosmic web’ images we’ve just been talking about – Hubble have very recently released 3-D images [see above] which were headlined in the media as ‘The First 3-D Images of Dark Matter’. How do these differ from the ‘cosmic web’ in terms of how they are produced?

RT: Well, they are supposed to be real observations showing exactly the same patterns which, as we've just said, are computer simulations. But as I said before, they are not direct observations of dark matter, since dark matter is, obviously, invisible. They are obtained by using the gravitational properties of dark matter, the gravitational distortion that dark matter is supposed to bring about, by using background galaxies as sources of light. Let me describe this in a little more detail. The light coming from background galaxies goes through a field of clumpy dark matter and gets distorted, the shapes of galaxies get distorted – this is what we call 'gravitational lensing' – in a special way depending on where the clumps of dark matter lie, just as a real lens distorts the image which sits behind it; a bending of light – but not really a bending since light travels always in a straight line in spacetime, but since spacetime itself is bent by the mass concentration, we experience this as a distortion. You see now already that in order even to formulate the observation we have to have this general-relativistic theory of spacetime, so you see how the significance of even our raw data is heavily dependent on our underlying world model.

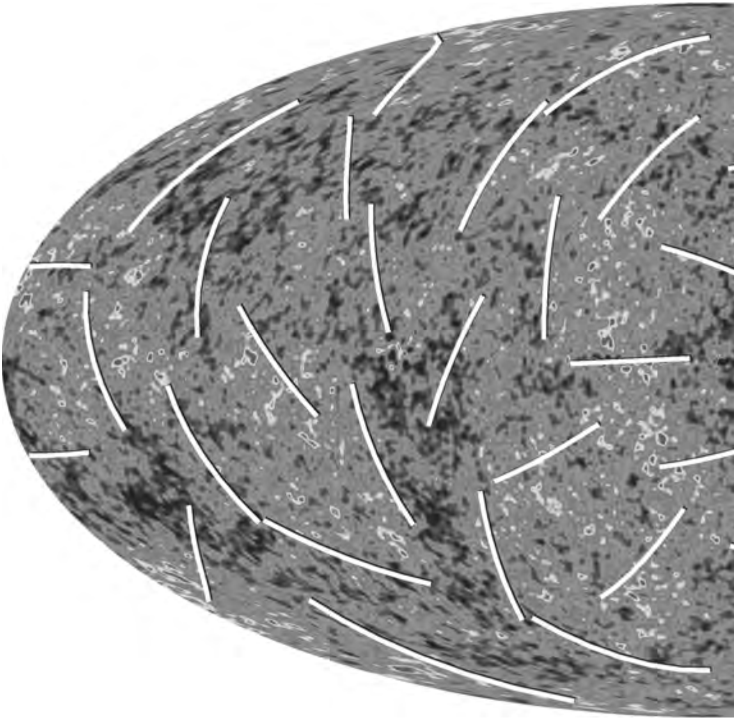
This relates back to what we were saying about the 'enhancing' aspects. There are pictures of visually impressive distortions of background galaxies that you can pick out 'by eye'; you can really see background galaxies being distorted in what we call 'Einstein rings' around the clumpy object – this is called 'strong gravitational lensing'. But that's not how the technique used to reconstruct the Hubble 3D images works. This technique is called 'weak gravitational lensing' and it works by observing tiny distortions of background galaxies, distortions in the shape of the galaxies. So if you had galaxies that were perfectly round as sources in the background and you observed them and saw their shape being distorted by 1 percent, or perhaps just a fraction of a percent, then you would be able to map exactly – by telling how the distortion behaves across the sky – the intervening dark matter distribution. Now, the thing is, we don't even have regular galaxies in the background. Instead we have galaxies that come in all different shapes and sizes, and so we are measuring distortions of shapes that we don't even know in the first place, because we don't have access to the undistorted shapes. That's where the enhancing techniques come in, because in order to get access to coherent distortions of galaxy shapes, you've got to make a statistical average. So, making the assumption that all galaxies are randomly oriented, with random shapes, if there were no coherent distortion, if you make an average, you ought to obtain zero. But since there is intervening dark matter – and that's where the enhancing techniques come in – you do these correlations, these statistical observations, and you find coherent patterns of distortions that do not average away because they are not intrinsic to the galaxies but are imprinted on them through the dark matter lens distortion. And, again, that's not something you could pick up by eye.

C: Another line of evidence is indicated by your work on acoustic oscillations of the early universe which are 'frozen' into the fabric of matter – a sort of primordial 'sound-fossil'.

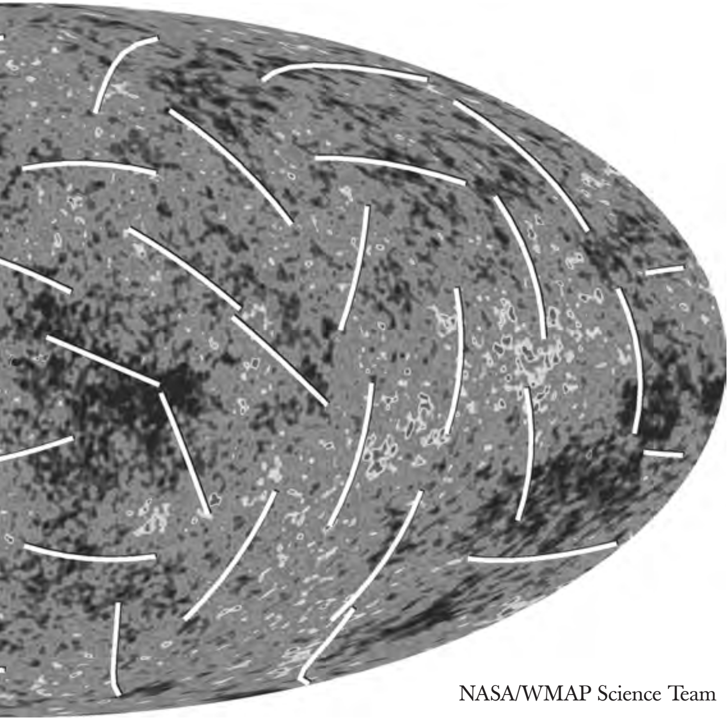
RT: Yes, these acoustic oscillations are, in a way, a natural fossil. The relevance of the sound waves of the early universe in general for cosmological parameters is that it's all relatively simple to calculate, because the universe was fairly young, and these density fluctuations which eventually grew to galaxies were still very small – actually one part in a hundred thousand. So they were so small that we can calculate them with very high accuracy, and we can follow their evolution up to the point where the CMBR was released, very accurately. And so from this we can confidently infer several properties of the universe at the time, for instance how much dark matter there was, how much visible matter there was, what were the characteristics of the seeds, how the seeds were sprinkled with scale, whether there were more seeds on small scales, on large scales, or whether they were uniformly sprinkled on all scales and so on. These sorts of things can be inferred from sound waves in the CMBR, because we know the physics very well. And so it's a nice spot between the very high-energy physics of the very beginning, which we don't fully understand, and the messy, non-linear physics of gravitational collapse and evolutionary structure that we do understand, but which gets difficult to follow because it gets very complicated, as you can see from the filamentary structures you obtain through the computer simulations we discussed.

C: How do you go about reading these 'recordings' of the Big Bang?

RT: We saw that the CMBR is very homogeneous because of its cosmological origin. But now we have very sensitive detectors, telescopes and satellites that measure this background radiation to a very high degree of accuracy. And if you look carefully enough, you will see that this CMBR is not perfectly homogeneous; it has temperature differences in it. So if you look with your telescope in this direction, we see a slightly colder spot, if we look in that direction we see a slightly hotter spot. We can build a map



[see below] of the sky, showing the temperature distribution of the background radiation. In order to measure the differences between the hot and cold spots with your telescope you need a sensitivity that's equivalent to the sensitivity you'd need with an optical telescope to see a mouse walking on the moon from the earth. So it's very tough. The guys who first did it in 1992 got the Nobel prize in 2006. These fluctuations you see in this map are the sound waves from the early universe, that's exactly



NASA/WMAP Science Team

what they are. When you throw a pebble in a pond you've got waves that go out in all directions; if you throw many pebbles in a pond you get a nice superposition of waves. In our case the pebbles were quantum fluctuations in the early universe, and they got frozen in at the moment this image was produced, and this is what we see – we really image them with our telescopes.

C: Calling them 'sound waves' is not just a figurative way of speaking, then?

RT: No, it's a technical definition: they're compression waves. The universe at this point was a plasma, that's a hot gas of electrons and protons, separated by the temperature, because the temperature was so high. So those were really acoustic waves, just like the waves in the air now as I speak, only they were travelling in the primordial plasma. And we can see them, as we can see in this map: it's real, it's been predicted, and we find this fantastic agreement with our models.

We usually talk about the CMBR being the uniform radiation coming to us from the Big Bang. When we talk about the temperature differences or anisotropies, we're talking about the very same radiation, but now looked at through a much more powerful telescope, so that you can highlight the temperature differences. It's one and the same thing, but you need a more powerful telescope to see the sound waves in it. I'm working more on the theoretical side of it, but people here also build such instruments. I'm interested in finding out how we can use those instruments to learn more about the conditions of the universe back then, or the conditions of the universe in the far future.

C: Let's return to the cosmological narrative, and to the 'seeds' you already mentioned briefly. For the first 300,000 years after the Big Bang, the universe is thought to have been remarkably homogeneous, surprisingly 'smooth'. The gravitational clustering which, it is supposed, ultimately structured this featureless continuum, was driven somehow by the properties of dark matter, via tiny fluctuations imprinted upon matter during the initial expansion.

Here dark matter seems to be invoked to answer a most traditional philosophical question: Why is the universe 'uneven' at all? Why does it consist of great voids and small concentrations of matter? Why is there something rather than nothing – or pure homogeneity, or chaos? The probing of anisotropy practiced by cosmologists rather recalls the original philosophical materialist, Lucretius, who, refusing divine intervention, posited an originary *clinamen* or 'swerve' which disturbed the atoms in freefall and led to the creation of nature. And unless some principle such as the *clinamen* intervenes, this heterogeneity, or what we could call the high information content of the universe, seems quite at odds with the received image of physical laws as linear and predictable. Are we to understand that some fundamentally nondeterministic processes must intervene at those crucial early stages to introduce these 'blueprints for differentiation'?

RT: Some fundamentally nondeterministic process, that's quite right, in fact. We just discussed the fact that these seeds are the ones that give rise to clusters, to galaxies, and eventually to all inhomogeneities in the universe. It's also the same seeds that we can observe in the CMBR from when the universe was very very young, 300,000 years after the Big Bang. And the ultimate origin of those seeds, we believe, lies in the very first fractions of a millisecond – actually 10^{-32} seconds after the Big Bang – during the period of very fast expansion which is called 'cosmological inflation', which takes the universe from a very small size up to cosmological scales. And at this point, since you are going so far back in time, the universe was compressed almost into a point, as it were. The overall size of the universe was so small that the microphysics governed by quantum mechanics [QM] was important. So you would have quantum fluctuations at the level of the whole universe, that then were stretched out to cosmological scales, and that's what the seeds were. Now, remember that all the evolution afterwards, the gravitational evolution of these seeds, is completely deterministic – we have the equations for gravity, we can follow them on the computer. But the 'seeding' of these fluctuations belongs to QM with its element of unpredictability, probability. The fundamental nature of it is quantum-mechanical, and so any understanding of this fluctuation is probably to be found in our understanding of what quantum-mechanical probability is.

C: This is where the intersection between fundamental physics and astrophysics comes in.

RT: Yes, it's where you close the circle: from the infinitely large scales of cosmology, you meet the infinitely small scales of particle physics, and quantum theory.

C: And presumably it's precisely here that the question of how to bring together GR with QM becomes a crucial and urgent one. To what extent does an adequate understanding of what happened in these first fractions of a millisecond after the Big Bang await the unification of these two foundational theories of modern physics in a successful quantum theory of gravity, whether that ultimately comes about in the form of some version of string theory, M-theory, loop quantum gravity, or something else altogether?

RT: Yes, that's absolutely fundamental, because all those big questions come together in the very first fraction of a millisecond, where all the interesting physics we don't yet know about happens. When, at the origin of the universe, we reach the highest possible energy scale, which is the Planck energy scale, at that point our theories essentially break down. That's the point where GR breaks down and we need to quantize spacetime itself. Remember, spacetime in our current vision of GR, is a sort of classical 'rubber–band' as it were, an arena in which quantum-mechanics take place. But when you get to this sort of energy scale, these types of miniscule length scales, it might be possible that fundamentally the quantization of spacetime itself begins to play a role. In other words spacetime stops being just an arena in which all the interactions of QM take place, but becomes a player in the quantum mechanical game, and nobody yet knows the rules of this quantum game.

C: GR and QM both break down – now, do they each break down independently in the sense that they no longer work at these extreme energy scales, so it's just a fuzzy area; or, do they break down because that's where they come together and you don't yet have a proper theory of how they can be combined?

RT: GR breaks down by itself because when you take the universe to size zero then – if you go analytically to zero in the equations describing the metric of spacetime – the zeros 'blow up' the equations, you end up with divisions by zero and our equations stop working. And the other problem is that no-one knows how QM and gravity work together because no-one is able to quantize gravity, for many different technical reasons. So yes, each breaks down on its own, and they break down together.

C: So that's a fuzzy area that's awaiting a successful theory of quantum gravity. Does it work that way, that you need a successful theory of quantum gravity in order to understand these very earliest fractions of a millisecond, these ten-millionths of a second after the Big Bang, or can cosmology itself help to solve the problem of the relation between QM and GR?

RT: Well, let me say that the fact that we don't have a successful quantum theory of gravity doesn't stop people from playing with some bold ideas. For instance, there is a scenario, called 'ekpyrotic universe', where the universe is supposed to be cyclic, that's to say it undergoes an infinite succession of expansions and contractions. So if you go back in time close to the moment of the Big Bang, when the universe is compressed at this incredibly high energy in this extremely small size, there might be some fuzzy physics, perhaps coming from extra dimensions, that makes it 'bounce back', rather than collapse to a point. Time does not start with the Big Bang, but rather you can describe the previous universes, as it were, before the Big Bang, by invoking some previously unknown phenomenon that actually prevents the Big Bang singularity, as we call it, from happening and gives you a bounce instead. So people do work on this kind of model at the level of their phenomenology, that's to say their effective description, but those are models that fundamentally are not strongly motivated at the moment. But people have these models in mind. So yes, it awaits resolution, but people are not *waiting* for it to happen.

C: The parameter z also plays a major role in constructing the cosmological 'narrative' of the universe. You are able to tell a story about what was happening at different stages of the history of the cosmos – *e.g.* 'the universe at $z = 20$'.

RT: This cosmological parameter z refers to redshift, and it has a very simple physical interpretation: it tells you that, for instance, if you're looking at the patch of the universe at $z = 20$, this is the state of the universe as it was when the size of the universe was twenty times smaller than it is today. This redshift is therefore not some abstract quantity, it's something we actually measure, by looking at the spectrum of whatever object we're observing. So if you look at a galaxy, the galaxy will contain certain elements, for instance hydrogen, iron, whatever. And these elements will emit light at particular wavelengths, particular colours: the 'signature' of the element. Hydrogen will have a particular line at a certain wavelength, iron will have a more complex signature consisting of a more elaborate pattern of lines. So we can determine, first of all, which elements are present in distant galaxies, because every element has got this set of colours which is particular to it, which comes from the quantum-mechanical structure of the atom. And by observing those lines, we can tell that on the Sun there is hydrogen, because we observe the hydrogen lines, and in the Andromeda galaxy there is hydrogen because we observe the very same lines. But the important thing is that the light of these spectroscopic signatures gets stretched while *en route* from distant galaxies to us, because of the expansion of the universe. So if the light gets stretched, that means that the wavelength of the light gets longer, and the light gets redder. In other words, we observe the same set of lines from a distant galaxy that we would observe from a local galaxy, but that set of lines is shifted towards the red end of the spectrum – what we call a 'redshift'. So by measuring the amount of redshift, we can measure how much of a stretch there has been between us and that galaxy. We can measure the redshift and we know whether this object is far away or nearby. It's uniformly shifted toward the red end of the spectrum.

Of course, as I mentioned before, there is an assumption which underlies everything here, and which is very strong, actually, especially from an ontological perspective. We assume all along – and we couldn't do without it – that the laws of physics are the same here, on Andromeda, and at the very beginning of time, which is a very major assumption. But there is little we can do if we don't make this very strong assumption.

C: Historically speaking, one might even say that it was just this very strong assumption of the uniformity of nature on the largest scales, of the universal applicability of the laws of physics, that inaugurated modern science itself. Copernicus' overcoming of the Aristotelian tradition of 'saving the appearances' by asserting the truth (rather than the mere empirical adequacy) of his cosmological system ultimately paved the way for Newton's synthesis of celestial and terrestrial mechanics via his law of universal gravitation. Of course we now know that, while the Newtonian laws of motion and gravity hold to an extremely good degree of approximation for almost all phenomena ordinarily encountered (*i.e.* for the everyday macroscopic world in which gravitational fields are relatively weak and objects move relatively slowly compared to the speed of light), they represent at best an approximate special case of the still more general laws of Einstein's GR, in which the notion of gravitational force acting instantaneously at a distance is replaced by that of the curvature of spacetime itself. But here, unlike the world described by Newtonian mechanics, which is more or less entirely consonant with the 'manifest image' of the world we derive from ordinary experience, the universe as described by relativity theory is, like that of quantum physics, deeply counter-intuitive. This is perhaps above all the case with regard to our commonsensical notions of space and time, to which the Minkowskian-Einsteinian notion of a four-dimensional spacetime continuum appears to bear little if any resemblance. The very idea that the beginning of the universe with the Big Bang was not an event which took place *in* space and time, but was rather the very coming into being of spacetime itself, is one which most people have a great deal of trouble coming to terms with. More difficult still is the related notion that there is no such thing as the 'objective present' – that there can no more be an objective division of the world into past, present and future than there can be an objective division of a region of space into east and west, or here and there. And at the submicroscopic levels where we enter into the utterly baffling world of quantum probabilities, things become a good deal stranger still. Here not just some but *all* of our habitual notions of space and time appear to break down completely, to become entirely meaningless.

All this gives rise to a number of questions relating to the very meaning of cosmological statements regarding time. For example, regarding the redshift observations which you have just been telling us about – by measuring the relative distances of observable galaxies in this way, you are also peering back into time, and determining things about the universe billions of years ago, when it was considerably smaller than it is today. These measurements, as you have indicated, are also crucial in estimating the age of the observable universe, which cosmologists have now dated rather precisely to 13.7 billion years. Such statements seem to be readily comprehensible and their meaning unproblematic. To what extent is this an illusion fostered by the isomorphism of such statements with everyday statements involving time? Must we not in some sense suspend our intuitive, commonsensical (and implicitly anthropomorphic) notions of time in order to properly comprehend statements about time in cosmology and in physics more generally?

RT: Well, as I was describing, the physically observable quantity is the redshift of the objects. It then turns out that the correspondence between redshift and cosmological time – when you do this mathematically through the equations of GR – depends on what the matter-energy content of the universe is. In other words, it depends on the relative amount of dark matter, dark energy, visible matter, radiation and so on. And so time becomes a function of the very properties we are trying to reconstruct.

C: Time evolves along with the universe.

RT: Yes, perhaps you could say that the link between the observable properties of the universe and its history as parameterized by cosmological time, goes through the very same properties of the universe, that is to say, its mass-energy density and its cosmic energy budget, which is interesting, because time becomes a function of them. At its heart this goes down to the fact that GR is a theory that links geometry on one hand, and the matter-energy content on the other. So we have matter which tells spacetime how to bend, and the bending of spacetime tells matter how to move. So we've got this inextricable mix of spacetime and matter-energy.

C: But if that is the case and if, according to GR, space and time are not to be regarded as anything like an absolute and universal stage against the background of which cosmic events play themselves out, but rather as flexible and dynamic actors – an integral part of the cast, as it were – in the cosmic drama itself, how is it that cosmologists are nevertheless able to define a concept of time that is applicable to the universe as a whole? Doesn't the passage of time depend on the speed of motion of the observer, and on the gravitational field in which the observer happens to be immersed?

RT: Well, in general, time *does* depend on the observer and the status of motion of the observer – different observers will observe different times – that's a generally acknowledged result of the theory of relativity, of course. But when you describe this evolving spacetime arena for the universe as a whole, then you introduce a sort of global co-ordinate system which you parameterise in terms of coordinates of time and space, *x*, *y* and *z*, and so the time you attach to this – which is the time that gets quoted as the age of the universe, and that I called above 'cosmological time' – would be the time that is measured by what we call a 'co-moving observer'. That is to say, a hypothetical observer that is swept along with the expansion of the universe, which we all are to a certain extent – our galaxy is swept along by the expansion of the universe. So that is what this time refers to: not just *any* observer, but an ideal observer that is postulated to be a co-moving observer, being swept along by the expansion of the universe.

C: But would the construction of this global spacetime co-ordinate system – this universal clock, so to speak – still be possible if the 'cosmic fossils' we have been discussing, such as redshift and the CMBR, revealed a non-uniform, non-homogeneous universe on the largest scales, rather than the surprisingly uniform, isotropic one which they appear to indicate? In a passage of his book *The Fabric of the Cosmos* which it seems appropriate to cite here, Brian Greene suggests that this background radiation not only 'gives astronomers what tyrannosaurus bones give paleontologists: a window into earlier epochs that is crucial to reconstructing what happened in the distant past', but that it is the *uniformity* of that radiation which is crucial in enabling cosmologists to define a concept of time applicable to the universe as a whole. The uniformity of the radiation is 'a fossilized testament to the uniformity of both the laws of physics and the details of the environment across the cosmos', and it is this homogeneity which, suggests Greene, makes it possible to meaningfully speak of a 'universal synchrony': 'if the universe did not have symmetry in space – if, for example, the background radiation were thoroughly haphazard, having wildly different temperatures in different regions – time in a cosmological sense would have little meaning.'[5]

RT: Yes, in fact the CMBR itself could be used by our comoving observer to define a cosmic clock, obtained by measuring the uniform temperature of the microwave radiation and monitoring it as it cools down with the cosmic expansion. But even in the extreme case where you had a cosmological expansion that proceeded differentially in different directions, a so-called 'anisotropic universe', instead of describing the expansion with just one number – redshift – then you would have one number for each direction. You could then possibly conceive of having different dimensions evolving differently with time. What is absolutely crucial, however, about the homogeneity of the CMBR that we observe, is that this informs us about the extreme uniformity of the conditions of the universe at the epoch when the CMBR was formed. The overall temperature of the CMBR is the same everywhere across the sky, even when we compare remote locations, points so far away from each other that light would not have had the time to travel between them by the time the CMBR was formed. So how is it that such distant points all have the same temperature today, if no causal mechanism could possibly have connected them? The answer is, again, 'inflation', the extremely short period of faster-than-light expansion of the universe that we encountered earlier when we discussed the mechanism that spread the quantum-mechanical seeds on cosmological scales. During

---

5. Brian Greene, *The Fabric of the Cosmos* (London: Penguin Books, 2004), 227-8.

inflation, the size of the universe grew exponentially, and patches originally close-by were stretched out to cosmological distances. This would explain why we observe them to have the same temperature today: they were once in causal contact and were then separated by the inflationary expansion. So the expansion of the universe during inflation can happen faster than the speed of light without violating the basic tenet of GR, since in this case it is spacetime itself that is stretching faster than light, not a particle or other object within it that is moving faster than light. I should also add that the fundamental mechanism that drives and powers inflation has not yet been established, even though there is no shortage of speculative ideas, some of them linked to dark energy, for example.

C: Another issue regarding time we might just mention briefly is the problem of the so-called 'arrow of time'. Do cosmologists take it for granted that time has a definite *direction*?

RT: Yes, because causality is ingrained in the very structure of GR. It's unavoidable because GR comes out from two assumptions, two axioms: one of which is the constancy of the speed of light, the other being the causal structure of space-time. So yes, it's built in.

C: But is *asymmetrical* causality is built into GR? Are the equations themselves not time-reversal symmetric?

RT: Yes, they are on a microscopic level, but the global structure of spacetime is such that you distinguish between timelike and spacelike intervals, and timelike intervals are intervals between spacetime points between which there can be a causal flow of information, whereas spacelike intervals are intervals where there cannot be such a causal connection. And because of the finitude of the speed of light – which again, is built-in to GR – the two domains are disconnected: you can't make a timelike interval into a spacelike interval. So in other words, there are spacetime points that cannot be causally connected, the ones separated by spacelike intervals, because for instance, two events that are simultaneous for a given observer will not be for another observer. So by going from one observer to another you would be able to change the order of events, which would clearly result in paradoxes if the two events were causally connected. For example, you would be able to find an observer that would see the effect precede the cause. So this causality is built into GR in a hardwired way.

But let me just come back to what you said about our intuitive ideas of space and time breaking down and becoming meaningless. And my reaction is – why shouldn't they? After all, our intuitive perception of reality is an *immediate* perception of reality that has developed from our brains and our experience of the world shaped by evolution, and clearly evolution knows nothing of quantum reality, nor does it know anything about the vast expanse of time and space of cosmology. And so, it's not astonishing that those notions become counter-intuitive since we are actually extending our capability of making statements about realities way beyond the scales which our brains were designed to interact with. And so it's not an astonishing thing.

Let me give an example, the example of mathematical symmetries, which I think is very fitting in this context. We all know what a spatial symmetry is – a sphere is spherically symmetric because however we turn it in 3-D space it looks the same, so that's a spherical symmetry. So we know what a spherical symmetry is like in space, and can associate a mathematical description with this symmetry. For instance the mathematical group that describes this symmetry in space is called SO(3). But now it turns out that we can equally well define more abstract symmetries that apply to subatomic particles, symmetries that pertain to the postulated internal state of those particles – isospin, for instance. So those are just transformation groups that do not transform, do not move things around in real space; they move things around in an abstract mathematical space that we have defined to have certain properties. But then those symmetries – which have nothing to do with real symmetries, but which take their origin from our observations of real three-dimensional symmetries in the world that we *can* perceive – those symmetries turn out to play a fundamental role in describing the state of those particles, the possible energy levels that those particles can take, for example. So these principles of symmetry play an absolutely fundamental role in all of physics. I think this is a case where we start from the immediate experience of the world, where we have a symmetric configuration of things, and then we take the very same tool, put it in a completely abstract mathematical space that *a priori* has nothing to do with any domain of reality, physical or otherwise. We apply it in this other context and end up with predictions about phenomena that were not observed before and, again, can *only* be observed through these 'enhancing' powers that we discussed before, and actually turn out to be true. This is an incredible application of extending, reaching out, from the time and length scales, and also conceptual scales, of our immediate experience, into domains that are definitely beyond the realm of our immediate perception.

C: The comment about the deeply puzzling, counter-intuitive notions of space and time in fundamental physics was of course not to say – 'How astonishing, how can it be?!' – much less to make some objection to them on the grounds that they don't conform to our ordinary or commonsensical notions. But, when it gets translated into ordinary language, when we're talking about space and time on universal scales, we can't help but assimilate what we're being told to what we know intuitively, and the question is whether our intuitive concepts are adequate to even begin to comprehend what's being said in physics.

RT: But again, I think it's another example of the phenomenon we were discussing before, when were talking about weak lensing – images that we take almost for granted, making dark matter 'visible'; yet if you are equipped with knowledge of how the evidence is collected, and how those images are produced, you understand that you cannot quite interpret them in such an immediate way. And statements about the age of the universe, I think it's the same kind of 'filter' that ought to be applied to them.

C: What is perhaps most remarkable about this whole discussion from the perspective of contemporary philosophy is that the 'big questions' about the universe as a whole which philosophers themselves have long-since regarded as constitutively beyond the limits of human reason, have now quite suddenly – that is, over the past fifty years or so – reappeared, though this time not as subjects of *a priori* speculation, but rather as concrete objects of scientific, cosmological research.

Your particular field of research is theoretical cosmology – the scientific study of the large-scale structure, properties and evolution of the universe as a whole. But apart from its scope – as we have seen, taking in both the inscrutably small and unfathomably large scales of the universe – how does theoretical cosmology differ significantly from other scientific fields?

RT: Well, as I said before, I think it's important to highlight that cosmology is very different from any other physical science in one fundamental respect: namely, that we can't perform experiments. We can only perform observations of the universe, which are intrinsically limited by many factors.

C: The distinction being that with experiments you can control parameters?

RT: And that you can reproduce your data at will. If you're not satisfied after a hundred trials you can do a hundred more, and gather more data, whilst for the universe we are intrinsically limited by the fact that we have only one universe, and we cannot create the universe a second time, as it were. And that's a fundamental distinction, one that's very important to understanding the nature of the cosmological enterprise. We can only make observations, look for correlations among observations, and make inferences using probability theory. So that's where probability theory comes into the story. For instance, if I have a theory that predicts that blue galaxies are more massive, I cannot simply grow a massive galaxy in the lab and observe if it's blue. But what I *can* do is to go out, observe as many galaxies as I can with a telescope, and then ask of my data whether I do observe such a correlation, that is, whether the more massive galaxies in my sample tend to be the blue ones. But that's a statistical connection between observed properties.

So that's a fundamental aspect, and it's limited in non-trivial ways. You might think our work is limited by the need for a certain budget to build a telescope of a certain size, for instance. But that only holds up to a certain point. For instance, for the CMBR, we have an effect that is called 'cosmic variance', which means, in other words, that we cannot get to these fluctuations as precisely as we would like, even by building bigger and better telescopes. There is an intrinsic limit to the ultimate statistical precision we can obtain, set by the fact that we have only one universe to observe. We can't travel to a very distant galaxy and observe the differences from another perspective, we're stuck here. And so this sets a limit on the amount of information you can ever collect, process, and analyse about the universe.

C: With regard to these intrinsic limitations upon, or conditions of, cosmological research, isn't this also in part where so-called 'anthropic reasoning' comes in – because the very fact of these, as you say, non-trivial limits, is something which has to be explicitly taken into account and, as it were, factored into the results of one's research? Of course, taking into account and 'correcting for' the 'subjective biases' of one's observations is part and parcel of all empirical science worthy of the name. However, in the case of cosmology in particular, there's something more fundamental at stake, isn't there, which follows from the apparently trivial and platitudinous fact that we cannot observe in an environment that does not support our existence? In other words, apart from the specific kinds of limitations you've just mentioned, there is also the basic fact that our evidence about the universe is restricted by the conditions necessary for our presence as observers.

RT: Yes, this is the so-called 'Weak Anthropic Principle' [WAP]. The way to understand this properly, I think, is not as if we are saying that human beings, or humankind, has a special role as observers *per se*. Rather, the question you could ask is: What does the fact that there are observers such as ourselves, tell us about the global properties of the universe as a whole – if anything at all? Obviously, we have to live in a very special place in the universe in order for us to be here at all. It's not just an average, randomly-picked place in the universe; we have to have the right conditions for life to be here and to be able to ask the question in the first place. So I think the only reasonable way to approach this is to start from the observation that we exist, and then try to consistently take into account the fact that all of our observations are implicitly conditional on the fact that we must be here to make them, and then carry on from there, in terms of probability statements; all the probability statements we make – such as, is our universe probable or not – we have to take into account this piece of information.

C: Part of the difficulty with the use of probability in theoretical cosmology is that it's difficult to understand how the 'frequentist' paradigm, the idea that a probability relates to a number of possible cases, could make sense. The frequentist paradigm is not only related to the repeatability of scientific experimentation but also in its origins, to gambling, to being able to play the same game over and over.

RT: Yes, absolutely. Although, from the point of view of the history of science, the Bayesian framework was born first, with Laplace, who applied it to problems in celestial mechanics, but was then superseded by what became the orthodoxy in the early decades of the twentieth century, by the work of people like [Sir Ronald Aylmer] Fisher. The frequentist approach to probability may be natural in the case of particle physics, because you have a certain number of particles, you count how many of them you have, and you count relative outcomes. But the Bayesian way of understanding probability is arguably a way which is more natural, in the sense that it's probably connected with the way that a naturally-selected mind works. Let me give you an example. If I ask, what is the probability that if I cross the road now I will be run over by a car, I am asking a question of an experiment, and I am naturally making a Bayesian inference as to what are my chances of crossing safely or not in that particular situation – I certainly don't want to repeat the experiment a hundred times and see how many times I get run over! So, in nature, actually, you want to be able to assess probabilities, chances, in terms of situations that are intrinsically unique, that cannot and will not be repeated. Now, the universe is clearly one of those cases. We have one universe – or, if it *is* repeated we certainly have no access to the repetitions, to other organisations or different laws of physics in the multiverse. And so we have one sample to work with. And we should stick to that, by understanding probability statements not as an outcome of frequencies, but rather as a state of knowledge. In other words, probability is in the eye of the beholder, in a sense. Probability is my state of knowledge conditional upon all the information and prior beliefs.

C: The problem of the applicability of concepts such as probability and chance to the universe as a whole has a long history. In his *Dialogues Concerning Natural Religion* Hume argued that, since the cosmos only happens once, we cannot hope to gain any knowledge of any regularities in how it is created. One can question the very propriety of attributing 'probabilities' to these initial or overall conditions of the world at all. Attributions of probability, it has been argued, depend upon observed relative frequencies in the world from which probabilities are inferred. To talk about the probability of a universe is, for this point of view, incoherent.[6] In a recent paper co-authored by Glenn Starkman entitled 'What's the Trouble With Anthropic Reasoning?', you raise precisely this issue, and suggest that some of these difficulties might be addressed by taking what you call a 'fully Bayesian approach to the problem' which, as you were just saying, would understand the prior as 'an expression of our state of knowledge'.[7] Could you, in simple terms, explain how Bayesian methods, and this notion of probability as a state of knowledge rather than as a relative frequency of outcomes, can work for a singular-case scenario such as the cosmological one?

RT: Yes, there has been a misunderstanding here, historically speaking, in that there has been this notion of probability as frequency, and that an event which happens only once cannot be deemed either probable or improbable – it just happens. But the connection between frequency of outcomes and probability is a limited one, which doesn't necessarily cover much ground, and in particular not the ground we're interested in covering, which is events that are by definition non-replicable. I gave the example just now of walking across the road. As I've said, most situations in which we are interested in making predictions about the outcomes of future actions are intrinsically unrepeatable. Let's take the most basic probability example, that of tossing a coin – one of the paradigmatic examples. If asked to assess whether the coin is fair, most of us would think of tossing this coin perhaps a hundred times and seeing whether there are, say, fifty heads and fifty tails, or sixty and forty, and then based on that, we ask what is the probability of getting heads or tails, and if that's 50 percent, we deem the coin to be 'fair'. And so, when we do these kinds of tests, paradigmatic tests, we are setting out to establish, as it were, a physical property of the coin – that the coin is either fair or not, meaning that it's either well-balanced or not. A die can be loaded or not, for instance. But, if you think about it for a second you'll realise that there's no such thing as a *physical property of the coin* that determines the outcome of heads or tails. In fact, if I was skilled enough and made my 'random' throw with sufficient finesse and precision, regardless of whether the coin was 'intrinsically fair' or not, I could get it landing heads 100 percent of the time. In other words, when I'm doing random tosses of the coin, the *randomness* is the key ingredient. The randomness of the toss means that my skill in tossing the coin is not good enough in order to determine in advance what will be the final outcome. But in principle, if I could determine the initial conditions of the toss with a high enough precision, I would be able to predict exactly, or to achieve any particular sequence I wanted, by having a better knowledge of the initial conditions of the problem – since, for non-chaotic, classical systems at least, the physics is completely deterministic. So by tossing a coin, we're not testing it for fairness, we're not measuring a physical property of the coin. Rather, we're making a statement about our state of knowledge of the randomness of the toss. In other words, we're making a statement *about our knowledge of the initial conditions of the problem*.

---

[6] These formulations of the objection are taken from C. Callender, 'Measure, Explanations and the Past: Should 'Special' Initial Conditions be Explained?', *British Journal of the Philosophy of Science* 55, 2004: 204 and L. Sklar, *Physics and Chance* (Cambridge: Cambridge University Press, 1993), 313, respectively.

[7] Roberto Trotta and Glenn D. Starkman, 'What's the trouble with Anthropic Reasoning?', *AIP Conference Proceedings* Vol. 878 (2006), 323-329.

So, how does this fit into the discussion of probability? Well, probability as a measure of *frequency* is one possibility: I define a probability intrinsic to the coin as a physical property of the coin, as the number of tosses divided by the number of tails of my series. But in the light of what I've just said, it's perhaps more useful to regard this not as a measurement of a physical property – since this property doesn't exist, as shown by the fact that I can completely change the outcome without changing physically the coin, just by changing my state of knowledge about the system I'm investigating … So it's perhaps more interesting to look at probability as expressing not an *intrinsic property of the objects* of study that has to do with their behaviour over long sequences of repetition, but rather to see that it has to do with *our state of knowledge of the object* based on our previous interaction with the object, the previous data. In this way, I can iteratively update my state of knowledge as new data come along. Based on previous knowledge – what we call the 'priors' – we can update it through new observations and get to a more informed state of knowledge.

Now, to go back to the universe, clearly we have no access to a repetition of the universe. But what we *do* have is access to information about the particular realisation we live in, and so by using this Bayesian technology, as it were, we can make statements not about the probability of an outcome of an infinite series of universes which is only posited *ad hoc* – which is ontologically debatable, in my opinion – but we can make statements about our state of knowledge of the particularisation that we happen to observe, which gets more and more informed and refined as we gather more and more information. Of course, all I've said here about probability holds at classical level – physical systems as deterministic. When we go over to the quantum level where probability is an intrinsic feature of the system, then the discussion has to take this into account, which opens up a completely new can of worms.

C: What you've said about Bayesian techniques certainly seems to problematise Quentin Meillassoux's recent critique of probabilistic arguments as applied to the universe itself, given that this critique appears to limit itself to narrowly 'frequentist' construals of probability.[8] But Meillassoux also takes issue with applications of anthropic reasoning which begin by envisaging a multitude of logically possible worlds – worlds in which the physical constants differ from those of the universe which we actually observe – and which then, having calculated that the probability of universes which permit the conditions necessary for life is astonishingly low, go on to infer that some hidden necessity must be at work which uniquely determines the constants of the observable universe.[9]

---

[8] See present volume 64-7, and Q. Meillassoux, *Après la finitude* (Paris: Seuil, 2006), Ch. 4.

[9] See present volume 77-8.

Meillassoux's argument is pitched at a purely *a priori* philosophical level, but the problem of the so-called 'fine-tuning' of the physical constants of the observable universe is a rather precisely-defined problem for cosmology, one which would seem to cry out for an explanation. While one will agree with Meillassoux that these 'fine-tuning coincidences' in no way license the reintroduction of teleological explanations such as one finds in the so-called 'strong' versions of the Anthropic Principle [AP], there is nevertheless a very real question here, is there not?

RT: Yes, indeed, from the point of view of cosmology and theoretical physics, the issue of fine-tuning you refer to is precisely the question that string theory has set out to answer – and so far has *failed* to answer. Which is to say, the hope of string theory – which is a theory that hopes to explain in heavily mathematical fundamental terms all of the structure of the particles and interactions in the universe – the hope was that it would turn out that there was a single mathematically consistent and logically possible realization of the theory, one which would account for all phenomena, structures, symmetries, particles, interactions, and so on. It didn't turn out to be the case, however. We now know that string theory has many different possible 'realisations', different corners of string theory space that are all equivalent to each other in some way, but none of which is unique. So it doesn't seem that the promise of string theory of being *the* final theory of physics – in terms of being unique and explaining all the phenomena – will be realised.

C: The hope was that it would explain those twenty or so free parameters of the Standard Model – the values of the constants which have to be, so to speak, 'written in by hand' – that are always invoked in discussions about fine-tuning?

RT: Yes, the hope was to explain in a unique and fundamental way all the parameters, and all the symmetries as well. But now, this hasn't turned out to be the case, and so we're stuck in a position where string theory doesn't make a unique prediction, as one had hoped, since there are multiple realisations of string theory which give you what is called the 'landscape' of solutions, which is a multidimensional mathematical object. It's called a 'landscape' because it's configured in terms of 'mountains' and 'valleys', and it turns out that at the bottom of each valley there is what's called a 'vacuum state'. Now, each of these vacuum states at the bottom of every valley represents one possible outcome for the universe. All this, so far, is of course mathematical theory, and so the question is to know which of these valleys in the landscape *our* universe occupies. But the number of possibilities for these logically possible universes, which Meillassoux mentions in a philosophical context, possibilities which are actually realised in this mathematical theory, the number of these possible universes is huge – it's something like 10^{500} – a huge, huge number. So again we have to resort to statistical techniques in order to analyse this landscape of possibilities.

The question then is, given this 10^{500} universes, our universe corresponding to the realization has been singled out in reality – how do we go from these potential universes to the actual, realised universe that we observe? This is where AP comes in, in saying that we have to count how many of these valleys are habitable. And this will restrict enormously the number of viable possibilities. Of course, we could not happen to live in one of the valleys which do not support life, say because the constants of nature there are such that life is not possible. And so you see modern physics seems to flesh out, as it were, in a very mathematically hard way, in the form of the landscape of string theory, precisely this idea of logically possible universes mentioned by Meillassoux. And now AP comes in as a possible solution, to try to explain the contingency of *our* particular realisation. Whether it's successful or not remains to be seen.

I personally have this criticism of this landscape of string theory: first of all, it's all dependent on the assumption that the heavily mathematical theory that describes this landscape is correct in some sense. And secondly, it introduces this plethora of universes, or alternative realisations, that are non-observable in principle. It introduces lots of possibilities that remain in the domain of the potential, just in order to explain how it comes about that we appear to inhabit a particularly fine-tuned realisation. But the moment you open up the space of infinite different universes you cannot observe, I think you are falling on the other side of this thin line dividing scientific enquiry from pure speculation, which cannot be scientifically tested. Which is fine – I don't want to give you the impression that I'm against these kinds of speculations. I'm only against them when you claim that you are able to do quantitative tests on things which, meaningfully, cannot be tested.

C: Indeed, in the paper mentioned earlier you dismissed the multiverse scenario precisely because, firstly, it seems not to be very economical, in terms of Ockham's razor; and secondly, because, as you have just said, it's not testable. Now, to take up the second point, it's obviously not 'testable' in any straightforward positivistic or verificationist sense; yet we know that a lot of things in modern physics are not testable in *that* sense. Is it not perhaps conceivable, however, that a number of quite different theories, coming from different domains of physics, perhaps as solutions to quite disparate problems, might ultimately all seem to point in the same direction – that is, in the direction of the multiverse scenario? In other words, one might reject the idea that fine-tuning *alone* is strong enough evidence to postulate a multiverse, but what if it turned out that there were other, independent reasons, to favour it? One thinks, for example, of Everett's 'many-worlds' interpretation of QM, or the very fact, as you were just saying, that string theory seems to admit of a multitude of 'solutions', or possible realisations. Is it not conceivable that a number of such theories, or interpretations of theories, might ultimately amount to a sort of evidence – indirect evidence, granted, but mutually corroborative – for some version of the multiverse idea?

But if not, what are the remaining alternatives? Do we just say that the values of these free parameters are 'brute facts' that we simply have to accept without any further explanation? But to say that – to say, in effect, 'The universe had to be *some* way, so why not *this*?' – that seems to be against the spirit of science itself …

RT: Yes, absolutely. But you see I think the problem here is that with string theory and the landscape, and this accumulation of extra layers postulated to explain physical reality, what we are doing in effect is moving away from trying to find out what are the laws of the physical universe; we are effectively crossing the boundary into trying to determine *meta*-laws governing the laws we have discovered in the first place. So if you think of these constants – one can say this is merely a brute fact, that that's just the way the universe is, but as you say, we're not content with that, we want to push forward and dig out another explanation. And one hope would be that it was possible to use this very powerful principle that we've used very successfully in the last couple of hundred years, which is the principle of symmetries. As I discussed before, these symmetries do not have to be tied up with real world symmetries – they might be the most abstract symmetries that live in a mathematical space. If those symmetries were in place, one would perhaps be able to explain these constants, because only a specific set of symmetries would allow for those particular values. For example, if dark energy is a manifestation of a cosmological constant, than the value of this constant is a very small number, and yet it's non-zero. If it were zero, everybody would be happy because – even though on the real line of numbers zero has a dimension or length of none, of zero – in fact zero is an extremely special place, so if something is zero in physics there's a symmetry which requires, which demands it to be zero. But if something is non-zero but extremely small – say 124 orders of magnitude below what you'd expect it to be – this is an astonishing fact that cries out for explanation. It could just be a brute fact and we might have to accept it as such and that's the best we can do. But, what people really are trying to look for, is to uncover the fundamental structure that will explain the smallness of this number when compared to the known energy scales in physics. So we are looking into discovering the laws or the mechanisms that possibly underlie and explain those numerical values. But even if we were to discover those laws in the form of a Grand Unified Theory or whatever – and we are not there yet – the question would remain: What is the meta-law that singles out *that* specific set of symmetries in the first place?

C: There's the risk of an infinite regress.

RT: Yes, exactly. That's what I'm trying to say. So, we're not giving up yet, but I can already peel off this layer and see where we're going.

C: The fact that you might end up with an infinite regress isn't a reason to stop.

RT: No, absolutely not …

C: There's a regulative ideal in play, such that you keep pushing on …

RT: Yes, absolutely. But you were asking whether it was possible that this explanation for fine-tuning would be testable or whether there would be enough cumulative indirect evidence. Again, you can always push the game one layer down, and find yourself asking deeper and deeper questions, and this is an infinite regression that is difficult to break, whose solution is not in sight, especially after string theory didn't offer such a way out.

C: In this respect Meillassoux introduces his distinction between chance and contingency as a sort of shortcut, or regress-stopper – he says, in effect, that you *can't* go back another level since there's an absolute, radical contingency which can't be submitted to any law whatsoever …[10]

RT: Yes, whilst cosmologists have, at least in principle, these meta-laws governing even the contingency of our universe.

C: We said that your own rejection of the multiverse proposal rests firstly upon the impossibility of experimental confirmation, and secondly upon its apparent flouting of Ockham's razor. Again, sticking to the first point for the moment, what if it turned out that something like string theory *did* ultimately manage to consistently account for the phenomena on all scales – in such a case, would experimental confirmation still be important?

---

[10] See present volume, 76.

RT: Certainly, yes, I would say so. I described before how our work involves a kind of cycle of data-gathering, modelling within a theoretical framework, and observational confirmation. The trouble in this loop comes when you get to a certain point where theories are constructed in such a way as to avoid experimental confirmation or falsification altogether. So when you get to the point where you need to postulate a possibly infinite number of unobservable parallel universes in order to explain why the constants of nature are the ones that we now observe – this, I think, crosses the boundary of scientific, verifiable theories; because for such theories, experimental or observational input is *designed* to be impossible.

C: And this brings us to your second objection, that such theories needlessly postulate entities. But isn't it possible that in the future you will be faced with the alternative of accepting theories which account very well for phenomena, but which cannot be experimentally confirmed, on the one hand, and experimentally-confirmed theories which permit a relatively inferior mastery of the phenomena, on the other? In other words, is there a disparity between the potential reach of speculative theories can have, and their grounding on experimental evidence?

RT: Yes, and dark matter is an instance of this. Some of this disparity is closed, or will be closed, by improvements in experimental instruments; so, we'll build bigger, better detectors, and we'll get there eventually – even though one has to bear constantly in mind the limitations to our knowledge that are peculiar to cosmology and that I was mentioning before. But the problem is where this theoretical reach is exercised in a domain where experimental proof or disproof cannot happen *in principle*. At this point I think you are losing all the power of theory, and from a scientific point of view you give in to pure speculation, which has no testable consequence and therefore is outside the proper realm of anything we could call scientific investigation. And I think the multiverse idea is an example of this, since even if these parallel universes were real in some sense, they are constructed to be undetectable because they are outside the reach of any particle, any possible experiment you could possibly do, and so you have to question what type of reality you could attribute to this theory, if any.

C: But hasn't the progress of modern science been precisely this movement towards extremely counter-intuitive ways of thinking? Most of us find even the most basic statements of modern physics counter-intuitive. They seem to be talking about a world entirely alien to that in which we live every day.

RT: Does the progress of science show us that we are going inevitably towards a realm where our intuition doesn't apply? I think there are a few things to mention here. One is what has been termed the 'unreasonable effectiveness of mathematics'[11] – why does mathematics describe the world in the first place? It can be argued that mathematics is ultimately just a product of the mind, which is arguably a manifestation of our brain structure, which, in turn, as a biological entity, must be a product of evolutionary forces that have shaped our cognitive behaviour in terms of responses to the world. But then this wouldn't explain why we're able to grasp things like QM or GR, of which we have no experience at all. I'm not sure whether there is an explanation for the fact that there are things of which we don't have any immediate experience – QM, something which is completely counterintuitive, weirder than you could possibly think – but which are accounted for by our mathematical constructs. This for me is the biggest puzzle of all – why should mathematics have anything to do with physical reality, and why should physical reality conform to this very abstract product of our minds? I don't have an answer for this question, but I think it is something that tends to be swept under the carpet, in operational terms.

---

[11] Eugene Wigner, 'The Unreasonable Effectiveness of Mathematics in the Natural Sciences' in *Communications in Pure and Applied Mathematics* Vol. 13, No. 1 (New York: John Wiley and Sons, Inc., 1960).

C: It's perhaps precisely here that the convergence of physics and philosophy – their shared space of problems, so to speak – becomes most visible. Indeed, the very questions you have just posed – 'Why should mathematics have anything to do with physical reality?' and 'Why should physical reality conform to this very abstract product of our minds?' – are precisely the problems which Kant set out to definitively resolve in his *Critique of Pure Reason* and *Prolegomena to Any Future Metaphysics.* Kant's solution, of course, is comprised within what he called his 'Copernican experiment' in philosophy, which basically states that the reason why physical reality conforms to our mathematical concepts is that these concepts provide the 'synthetic *a priori*' *conditions* of natural science itself. In other words, empirical reality conforms to our concepts because these concepts are not derived *from* experience, but exist rather *for the sake of* experience: that is to say, they make experience, and the objects of experience (and for Kant this meant, first and foremost, the objects of natural science) *possible*. This was perhaps a compelling solution in terms of the mathematics and natural science of Kant's own day – that is, Euclidean geometry and Newtonian mechanics – which, as we were saying earlier, are more or less entirely isomorphic with the middle-sized world of our everyday experience. But as you have just remarked, when it comes to twentieth century physics – to QM and GR – one finds no such isomorphism, and so the problem becomes far more difficult.

This is perhaps an appropriate place to touch upon some questions we were hoping to broach regarding a certain parallel we had noticed between the use of so-called 'anthropic reasoning' in cosmology – which has already come up in our discussion several times – and certain aspects of the Kantian legacy in contemporary philosophy. Brandon Carter, who first introduced the term 'Anthropic Principle' in 1974,[12] later had some cause for regret that he had not called it something else – the 'Cognizability Principle' or some such – given the somewhat inevitable misunderstanding that it entails some of kind of anthropocentrism or 'anti-Copernicanism', whereas the real point has to do with possible 'observational selection effects' entailed by ‘observership’ in general, not *anthropos*, or *homo sapiens* in particular. Carter’s original point was that it is a mistake to infer from the fact that we do not occupy a privileged *central* position in the universe the conclusion that our situation cannot be ‘special’ *in any sense whatsoever*. The problem with what he called ‘exaggerated subservience to the “Copernican principle”’ is the risk that, from the presumption of our *non-specialness* we might infer that we are *average*, and from this that we are *representative*, and hence *neutral*. In striving to avoid anthropocentrism in this way we would, paradoxically, be reintroducing it in another form, because we would fail to take into account the specific limitations on our knowledge entailed by the fact of the very special physical conditions which must be in place if we are to exist as observers – and be the specific kind of observers we are – in the first place.

---

[12] B. Carter, 'Large number coincidences and the anthropic principle in cosmology' in (ed.) M. S. Longair, *Confrontation of Cosmological Theories with Observational Data* (Dordrecht: D. Reidel, 1977), 291-8.

In this regard WAP invites comparison with Kant’s ‘Copernican experiment’ in philosophy. Kant faulted the metaphysical tradition which came before him precisely for failing to take into account the fact of the essential limits of our modes of cognition – that is, of the conditions which must be in place for cognition to be possible in the first place – and thus for assuming that the (epistemological) conditions of human knowledge were also the (ontological) conditions of things in themselves. In the most simple and general terms, Kant’s point was that one cannot know a thing in abstraction from the very conditions of cognition itself. Because previous metaphysics had not undertaken a properly ‘critical’ investigation of the epistemological conditions of its own inquiries, it had inevitably proceeded ‘dogmatically’ by assuming that its own conditioned vantage-point on things amounted to an unconditioned access to things as they are in themselves. Thus, as with WAP, rather than attempting to illegitimately infer metaphysically dubious anthropocentric conclusions from trivial or truistic premises, one might argue that Kant too was attempting to precisely *avoid* the anthropocentrism which follows from failing to take into account the non-trivial limitations upon and conditions of the possibility of cognition itself.

But however one interprets Kant on these matters, it has often been claimed that his 'Copernican turn' in philosophy, as a matter of historical fact, inaugurated a way of doing philosophy which, far from complementing the natural sciences by providing second-order epistemological critiques of their first-order claims, in fact runs counter to the 'Copernican' spirit of modern science itself by effectively placing man (or the knowing subject) back at the centre from which Copernicus had dethroned him. Meillassoux's *After Finitude* presents a particularly forceful example of such a cricitism.[13] According to Meillassoux, the mainstream of philosophy since Kant cannot but fail to make sense of the literal import of cosmological and other scientific statements about the universe so long as it remains within the paradigm of what he calls 'correlationism' – this being the name he gives to the long-prevailing consensus regarding the supposed absurdity of the idea of 'things-in-themselves' (i.e. the idea of obtaining knowledge of things as they are regardless of human experience), along with a positive doctrine which states that all possible objects must be understood strictly in terms of their correlation with either possible experience, subjective consciousness, intentional acts, language, conceptual schemes, or theories. A strong 'correlationist' position on dark matter would not merely claim (like WAP) that our cosmological models are necessarily conditional upon certain cosmological parameters which permit the empirical advent of life and of consciousness, thus putting us on our guard against neglecting these factors in our reasoning. It would affirm the much stronger thesis that in principle the very existence of dark matter is conditional upon our cognition of it, that astrophysical objects can only be said to *exist* by virtue of the conditions of our cognition – whether these conditions are intersubjective linguistic networks or the historical corpus of mathematical learning. In sum, dark matter exists, according to the correlationist, only 'for us' but not 'in itself'.

---

[13] *Op. cit.* For a critical appraisal, see R. Brassier, present volume, 15-54.

Now, this seems particularly difficult to accept in the field of cosmology where, as Meillassoux points out, 'experimental science is capable of producing statements concerning events anterior to the appearance of life and of consciousness.'[14] How, within the 'correlationist' framework – which is happy to accept scientific statements only along with the caveat that they are true only 'for us' – can we understand the meaning of a statement which purports to provide us with knowledge of entities and events which existed billions of years *before* there was any 'us' to cognize them?

The question is fundamental: does scientific objectivity allow us to in some sense 'get out of ourselves', to transcend the conditions of our experience and to achieve genuine cognition of the universe in itself? WAP appears to be optimistic here, suggesting that, precisely by taking into account possible observational selection effects and other biases intrinsic to our existence as observers, this is precisely what can be achieved. What we might call the 'Correlationist Principle', on the other hand, forecloses the question immediately, in accord with its assumption that everything is necessarily conditional upon the conditions of our cognition.

---

[14] Meillassoux, *op. cit.*, 24.

Now, these questions are obviously somewhat philosophically involved, and perhaps belong to epistemology rather than science proper. But one might think that, if anywhere in modern science they become urgent and uncircumventible, it is here, in the domain of cosmology. Similar questions have, of course, been central to the problem of the correct metaphysical interpretation of quantum physics for almost a century. Do you think that your own work, and modern cosmology in general, might ultimately be able to contribute something towards resolving these long-standing disputes? To what extent are such problems real and live ones for the working physicist or cosmologist? If a 'naïve realism' is no longer a real option, both because of what modern science has discovered and the sheer tide of philosophical arguments against it, what are the remaining alternatives?

RT: Well, first of all, I would certainly subscribe to the idea that the knowledge we gain of these objects which preceded the possibility of us experiencing them comes out of something like a time-shift – it's like time-travel. Because we have to remember that as we look back in time by observing distant objects we are witnessing different stages in the evolution of the universe. However, when we look at a distant galaxy we don't, of course, obtain knowledge of how the universe is 'now', as we observe it – indeed the whole concept of simultaneity is rather counter-intuitive in relativity, as we discussed. Rather, we have knowledge of the universe as it was when the light first left it. So now, when we look back to the very beginning of the universe, in a way we are looking at a point of the universe which may be billions of light years away, but since the Big Bang happened everywhere in the universe, and since we assume that the universe is isotropic – that there is no special place in the universe – then we are also looking at the universe as it was 'here', in a sense, in our location, only timeshifted.

But you asked whether scientific objectivity – perhaps supplemented by AP, purporting to correct for subjective bias – whether it allows us to have a genuine cognition of the world in itself. In science we can certainly have this sort of counter-intuitive narrative of disembodied entities, that we like ourselves to compare with. However, the selection effects expressed by AP remind us that such disembodied observers are an artifact of our cognitive process, and that quite on the contrary we have to carefully consider the physically and biologically necessary conditions for our presence. But we have to bear in mind that in order for AP to work, we have first of all to postulate, to apply this selection effect to a collection of samples, be it a class of objects in terms of realisations of the universe, different parts of the multiverse, multiple inflationary patches, whatever. And after that you need to define a reference class of observers – and this is the criticism I make in the paper you mentioned earlier. You have to define what counts as an observer in order to establish what is the probability of our being in such and such a universe. We have to define very precisely what it means for us to be observers: what is the reference class of observers we belong to – cockroaches, for instance – do they count as observers or not? That's a very fundamental point.

I think this is relevant to the question of the relation between AP and the 'Correlationist Principle' in the sense that, in order to achieve logical consistency when considering a reference class of observers, we must require consistency between the outcomes of inferences made by different members of the same reference class of observers. And this, I think, is very relevant with regard to correlationism. In other words, in order for probabilistic inference to work, we have to require that different observers, say us and some alien species on Andromeda – if we postulate that they use the same logic, that the rules of logic are valid throughout the universe, which is again one of the main postulates – we have to require that different observers in the same class of reference will necessarily achieve a consistent inference by making the same observations. And so I think that debunks, in a way, the Correlationist Principle. Because if this is true – AP supplemented by the requirement of logical consistency between observers in the same reference class – if this is true, then necessarily we don't have this freedom anymore for different observers in the same reference class to experience the world in a different way. In other words, the arche-fossil[15] has got to be an entity of its own that can't be processed at will by interaction with different observers of the same reference class – *if* AP is to work at all.

---

[15] See R. Brassier, present volume, 15-6.

So in other words, I think what you have represented very nicely in your question is two different ends of the spectrum of possible cognitive experiences: correcting for subjective bias through a careful use of AP, on the one hand, and introducing a new way of subjectively experiencing the world in the correlationist approach. I suspect that the two of them can't live together. I would claim that for AP to work in a consistent way – if we accept logical consistency as one basic rule of inference, for instance, which it's hard to do without – then it requires consistency among observers in the same reference class, however defined. If this is the case then it means that the entities upon which we condition in our application of AP as a selection effect – those entities must have some common, intrinsic properties of their own, properties which every observer in the reference class of observers reasoning consistently has got to agree upon.

C: This introduces the problem of relativism, of alternative conceptual schemes. But correlationism need not necessarily entail relativism, since even if all observations agreed, and even agreed *necessarily* – as in Kant's case, where the transcendental conditions are *a priori* (that is, universal and necessary) – the correlationist would still insist that intersubjective consensus is an insufficient basis upon which to claim that such observations reveal properties of things *as they are in themselves*. In fact, the correlationist would claim that it is precisely this consensus amongst observers in the same reference class which makes the objectivity of objects possible, thus collapsing the ontological problematic into a matter of intersubjective agreement or heuristic pragmatism,[16] which is precisely what the critique of correlationism seeks to avoid.

To put it as starkly as possible, the fundamental question here is whether there is any prospect of obtaining knowledge of things as they are in themselves – regardless of there being actual or possible observers – or whether it is something constitutive about cognition that it will always be a matter, not of 'nature in itself', but only of 'nature as exposed to our method of questioning' (Heisenberg)?[17] Kant's metaphor was one of reason as a judge, 'constraining nature to give answers to questions of reason's own determining',[18] and perhaps in your account of the methods and objects of theoretical cosmology you have already implicitly ratified this metaphor, whilst making it clear that it is nevertheless by no means a question of a simplistic 'correlationism'.

Another way of approaching the issue is in terms of the problem of the theory-dependency of observation which we touched upon earlier. You said that all the necessary theoretical and instrumental mediation required to access cosmological objects amounted not to a diminution but to an ‘enhancement’ of reality – almost as if there is a sense that one is ‘producing’ the reality. Does scientific knowledge, as you understand its process, fit more closely with the classical philosophical idea of knowledge as a kind of ‘copying’ or ‘representing’ of an already fully-determinate reality, or is there a sense in which the objects of physics have to be ‘constituted’ via the theoretical and technical ‘mediating processes’ you were describing earlier?

---

[16] See Meillassoux's critique of Goodman, present volume, 56-9.

[17] 'In classical physics science started from the belief – or should we say from the illusion? – that we could describe the world or at least parts of the world without any reference to ourselves […] [But] we have to remember that what we observe is not nature in itself but nature as exposed to our method of questioning.' W. Heisenberg, *Physics and Philosophy: The Revolution in Modern Science* (NY: Harper & Row, 1962), 43, 46. See also Kristian Camilleri's 'Heisenberg and the Transformation of Kantian Philosophy' in *International Journal of the Philosophy of Science* Vol. 19, No. 3, 2005: 271-287.

RT: Let me give you an example which I think illustrates how a reality comes into being through the scrutinizing power of the scientific methodology. Leaving cosmology for a while and turning to quantum physics – another field which is often on or across the boundary of interpretation and reality – if you take for example a *two-dimensional electron gas*, which is something that has been realized only in the last few years, thanks to various developments in sub-microscopic technology. This two-dimensional electron gas has a set of nice properties that we can investigate: we can

18. ‘When Galileo caused balls, the weights of which he had himself previously determined, to roll down an inclined plane; when Toricelli made the air carry a weight which he had calculated beforehand to be equal to that of a definite volume of water […] a light broke upon all students of nature. They learned that reason has insight only into that which it produces after a plan of its own, and that it must not allow itself to be kept, as it were, in nature’s leading-strings, but must itself show the way with principles of judgment based upon fixed laws, constraining nature to give answer to questions of reason’s own determining. […] Reason, holding in one hand its principles, according to which alone concordant appearances can be admitted as equivalent to laws, and in the other hand the experiment which it has devised in conformity with these principles, must approach nature in order to be taught by it. It must not, however, do so in the character of a pupil who listens to everything the teacher has to say, but of an appointed judge who compels the witnesses to answer questions which he has himself formulated.’ I. Kant, *Critique of Pure Reason* (trans. N. K. Smith, Basingstoke: Macmillan Press, 1929 [1789]), B xii-xiii.

put it into magnetic fields and see how it behaves, see quantised energy levels, and different types of effects which, in a way, are the expression of a potentiality which is in nature or in the laws of nature that we've discovered. But in a way it's a purely technological object – it was potentially in the structure of nature, but one might surmise that it has never been created before in the history of the universe, because it's a very particular object that needs to be very carefully engineered in order for those electrons to bind up in a certain type of state and then express or substantiate those abstract potential properties that our theories describe they have, and then go there, measure it and see what is real. So in a sense this is not just a step ahead of the process of setting up an experiment and making a verification; this is more about *creating a particular state of nature*, actualising potential properties of an object in order to display them in such a way that we can verify them. So in this sense we have achieved in some domains a level where we have a description of nature in terms of its fundamental properties, and we can engineer physical systems, and push them across boundaries that arguably have never been crossed in natural systems because of the very particular set-up that this requires, and so design and engineer new natural conditions that are actually artificial – new artificial natural conditions – which actualise the potentiality of our theory. And here you are at the boundary where you can ask of this system: well, that's a natural system because its actual properties are governed by laws which are natural laws, of course, but those particular properties that you are looking for, their actualisation is only possible in a highly artificial, highly engineered environment that we have now created.

C: A longstanding philosophical problem is how to separate out what belongs to the human input to reality and what belongs to reality itself. In the context of physics generally, and more specifically in the context of the kind of example you've just given, is that in principle even intelligible, this process of 'factoring-out'?

RT: No, I don't think that we can draw a clear boundary between the two. This is an example where we have a little liberally gone across the boundary both ways, and there's no way you can draw a line, but it's just a suggestion to say that there are systems that sit beyond the Galilean distinction of the impartial observer who sets up the experiment and then simply lets it go ahead on its own. We know that the observer plays a crucial role in quantum mechanical observations, and the whole paradigm of setting up an experiment and letting nature run its course in an impartial neutral way, I think it belongs to the past, since our decisions of which properties to observe and which to ignore, for example, will directly influence the system. So there are limitations to the Copernican Principle of the separation between observer and nature. I think science is going in this direction. In one way we are getting more and more sophisticated observations of reality, and at the same time those same observations, to an extent that is difficult to define, determine which reality one can observe in the first place, at both extremes of the spectrum – the microscopic world of QM, of course, and cosmology.

And the other thing that has to be said here is, if you peel away all the layers of the onion, for me it comes down to the issue of consciousness. Why consciousness? We have this 'correlationist' idea that the world wouldn't be there if there was no observer to observe it, but what do we mean by 'observer'? It's a problem that goes back all the way to the root of QM, Schrödinger's cat: What makes the wave function collapse, what makes the cat go from a position of living *and* dead to either living *or* dead? And again it's a fundamental problem for which there is no agreed explanation. It's more about the interpretation we give to the quantum theory. In and of itself, QM works perfectly well, it's only the interpretation as to the reality of the wave function that is disputed. Let me briefly summarise the interpretations. Firstly there's what is called the 'Copenhagen interpretation', which says that the wave function collapses into one of two states when the observer observes it. Now at this point we can question whether the observer is a machine, an electron or photon that hits the object we observe – so the universe would be observing itself all the time; or whether there is space, as people such as Roger Penrose would argue, for a special role for consciousness: consciousness would play the role of the fundamental observer that would make the wave-function of the universe collapse, like in quantum cosmology: in quantum cosmology you have the wave function of the whole universe.

C: But then you're introducing a strange gap into causality: a special agent.

RT: But that gap is in the equations, that's exactly the point: the equations of QM are deterministic. We've got the Schrödinger equation, and we've got initial or boundary conditions. And then the equations will evolve through time this mysterious wave-function, whose square gives you the probability of events happening. And when there is an observation the wave-function collapses from a superposition of different events to just the event that is observed. And so, the point is, everything is deterministic up to the point where the collapse happens, and we don't know what makes the collapse happen, and we cannot give deterministic predictions for the collapse, only probabilities. That's why the deterministic picture breaks down, we can only make probabilistic predictions about what happens: in the case of the cat, in the case of the seeds for the quantum fluctuations, and in the case of the universe. And there are different views. The Copenhagen interpretation will tell you that it is the observation that makes the wave-function collapse, and the alternative will die out, mysteriously. Then there is the 'many-worlds' interpretation, which tells you that at the moment an observation is made, the observer splits into multiple copies, each one of them observing at the same time different events, all possible events that can happen *do* happen, and that our particular reality is but one branch of this unimaginably vast tree. And to a certain extent there are testable predictions that have been done, that have excluded certain interpretations – the hidden variables interpretation, which was put forward by Einstein, has been partially excluded by tests of the so-called 'Bell inequalities'. But this remains very much a contentious issue, I think, and so we cannot really make up our minds as to what makes a wave-function collapse here and there, much less what makes the wave-function of the whole universe collapse, if anything at all.

But you see I think the whole point is that we try to make a narrative out of the scientific framework we're working in, so we tend to talk about cosmological time in pretty much the same way as if we were talking about our subjective time as we know it, we talk about the collapse of the wave-function without really knowing whether this object is just a model of reality or whether it has anything to do with the fundamental reality of the object, the object of the scientific enterprise. The fundamental reality of the 'nature' we're trying to investigate in particle physics and cosmology, I think, comes out from a hundred years of mathematical explanation as one or two things. One is a set of mathematical symmetries, which live in an abstract mathematical space and which give reality its structure. So for instance, conservation of impulse – as we know, if you throw a ball and there's no friction it will keep on going forever – comes from translational symmetry. Conservation of angular momentum comes from rotational symmetry. And then at the deeper level, you can say that conservation of mass, conservation of energy, come from other types of symmetry that are ingrained in the mathematical structure that we ascribe to reality. Now, when we try to uncover this structure through observations, the question arises: even if we were able, with supersymmetry or string theory, to uncover the fundamental structure of nature, the question would be, what principle put this structure in place in the first place? And the hope of string theory, for example, was that you'd find a mathematical theory which could only be consistently formulated within a certain structure: there was no other structure within which it could be formulated. And that would answer the question. But it didn't turn out that way: as we discussed, string theory has failed to yield that kind of paradigm, and Gödel's theorem, perhaps, puts a fundamental limit on how far such a programme can be carried out.

C: Yes, we note that you finish one of your public lectures[19] by juxtaposing a quote from Einstein where he asks 'whether God had a choice in creating the universe' with one from Gödel: 'If an axiomatic system can be proven to be consistent and complete from within itself, then it is inconsistent. It is impossible to find an all-encompassing axiomatic system which is able to prove all mathematical truths.'

RT: Gödel comes in precisely at this level of speculation, when you're trying to push your mathematical tools to the very extreme, to say, will I ever be able to formulate the structure of physical reality in terms of a set of mathematical symmetries that will describe reality in some sense, and then demonstrate, by requiring mathematical consistency, that this is the only possible set? The correlative Einstein quote I use is: 'what I'm interested in understanding is whether God had a choice in creating the universe' – *i.e.*, in imposing this set of symmetries. And Gödel's theorem, apparently sets a limit to this programme, tells us that there is no way every axiomatic consistent set of rules – mathematics – can be complete: for every such system there will always be a statement that is true, but cannot be proven from inside. So this seems to put outside the grasp of any such tool such a fundamental question, it seems to me.

---

[19] See http://www-astro.physics.ox.ac.uk/~rxt/html/public.htm#course

C: Thus leaving room for something to have 'planted' the seeds, so to speak …?

RT: It's a possibility. The fascinating thing is that everybody can make up his or her own mind on this. Leaving the door open for a designer – I don't know about that. But in trying to get out of intelligent design, if the solution is invoking an infinite set of universes that only exist in our mind, then I don't know whether this is any kind of solution. It doesn't seem to be a fundamental explanation in the sense in which we have always understood fundamental explanations before in physics.

If 'correlationism' insists that we can only posit objects as objects of possible experience, it seems to me that if we think of this idea of the multiverse – broadly speaking, this idea of 'pocket universes' everywhere, in some higher-dimensional space, with different laws of physics – it seems to be that by resorting to this kind of extreme complexification of reality, science has gone full-circle and is actually positing a series of objects which are definitely, by construction, outside the domain, not only of our experience, but of *any* possible experience. So, rather than reconciling philosophy with science, it seems to me that if you go down this route of the multiverse, you would be going full-circle and bringing science in line with philosophy, rather than vice-versa.

C: In that science would become extremely speculative?

RT: More than that, I think, it would really embrace the idea that in order to explain the one universe we observe, you need to postulate a series of unobservable universes devoid of any possible experience – so it seems to me that it's ironical, paradoxical, that certain ways of thinking of this problem will lead you to such a 'solution'.

C: Yet one might argue that the 'many-worlds' interpretation of QM, for example, while doubtless ontologically profligate, does at least possess the very real virtue of providing an interpretation which is both fully consistent with the equations and which avoids the idealistic, dualistic and vitalistic consequences of other influential interpretations. Leading proponents of the Copenhagen interpretation, on the other hand, have been prone to espouse an idealism so radical it would 'make even Berkeley blush' – one thinks, for example, of Wheeler's notion of a 'participatory universe' according to which 'the observer is as essential to the creation of the universe as the universe is to the creation of the observer.'[20] Similarly, the postulation of a 'multiverse' or 'ensemble universe' as an answer to the fine-tuning problem, AP being introduced in order to explain the apparent 'coincidences' in terms of an observational selection effect, seems in many ways more compelling than a teleological interpretation which would make life and observership a necessary outcome of uniquely specified laws.

---

[20] J. A. Wheeler, 'Genesis and Observership' in R. Butts and J. Hintikka (eds.), *Foundational Problems in the Special Sciences* (Dordrecht: D. Reidel, 1977), 27.

So with regard to what you have just said about the impossibility of separating out reality in-itself and our theoretical donation, or nature and the observer, would you put the point as a purely epistemological or methodological one – that it's simply too messy in practice – or would you say there's some legitimacy in this idea of a 'participatory universe', that observership is in some sense necessarily interwoven with the very fabric of the universe?

RT: Again, you'll find the whole spectrum of views on this, from the idea of the participatory universe, or the whole universe as a huge living being, to the most rationalist, scientistic point of view which says that the brain is just a very complex computing machine, consciousness just an emergent phenomenon. So you'll find a lot of different points of view. If I were to give an 'average position' of scientists I know, to position them on this scale, I would put most of them on the rationalistic, positivistic side of it. But having said that, clearly if one wants to be rational and consistent throughout, this implies restricting one's point of view regarding the possibilities of human experience to experiences that are open to any other physical system – you have to abide by the laws of nature without room for any other phenomena that might go beyond them. So far, consciousness is the one phenomenon that seems to be peculiar to humans, and whether this will ever be explainable in the same way we can explain the working of, say, a diesel engine, is a very open debate.

C: You've said a couple of times that, when it comes to the ultimate ontological interpretation of science, 'everyone can make up their own minds' – almost as if it's simply a matter of personal preference. Is this not a huge problem? In a way one might be disappointed, after all the great progress of science, in particular over the last century, to be told that science itself is unable to instruct us regarding its own ontological interpretation. It seems as if you're saying that one can 'cherry-pick' whatever interpretation one wishes, that science itself doesn't place any constraints upon the kinds of metaphysics one might be able to extract from it. But one might have hoped that science would have offered us clues – indeed, more than just clues – to these questions about the ultimate nature of reality.

RT: I think it's too much to hope from or to ask of science, to put the onus of making this decision, passing this judgement, on science itself.

C: But if not science, then who?

RT: I think the methodology of science itself finds its expression and its field of applicability within a domain that is ever-growing but that is delimited by the way science explicates itself in a reflective way. So the main way you can apply science is defined by its methodology; but the context in which you place this methodology and this narrative cannot be analysed by the same methods. In other words you need a bigger arena in which to place science, and I think it's ill-conceived to try and ask of science to determine those answers – they should come as an input from the outside, as a different discourse.

C: But we *do* look to science to guide us in these questions, and if science is itself not capable of providing these guidelines for its own ultimate interpretation, or if the question of its ontological or metaphysical interpretation is something extraneous to science itself, then it seems as if science itself will never be able to do what it is its explicit aim to do, which is to tell us what the structure of reality is.

RT: I disagree that this is the goal of science – to tell us about the structure of reality itself. I think we can only describe it as a logically-consistent narrative of the structures of our models, models that conform to the observed inputs of the world, and in those terms the most we can ask of it is for it to be *consistent*. In fact that's the way we expand its domain of applicability. But we ask only for a consistent narrative of the world – I think it's hopeless to ask of science to give us a 'true reflection of reality'. The only thing we can ask from science is to provide us with a logically-consistent, experimentally observable, predictive narrative of a model of reality. Apart from that, in order to interpret this model, to delimit its applicability, we need another form of discourse which necessarily sits beyond the methodology of science itself.

C: A philosophy of science?

RT: Yes. Because science itself, in its becoming, is mindless.

C: So it would seem, from all that you've said, that cosmology works precisely on the boundary between this 'becoming of science' and philosophy.

RT: Yes, because it's by no means a sharp cut-off point: there is a foggy region where you don't really know what you're doing.

C: And presumably that is the most exciting region to be working in?

RT: Yes, it's a region where you don't know where the boundaries are. It's very exciting to be able to give a small contribution towards clearing this fog, and mapping this region. But I don't think it's clear. There might be an actual gap somewhere, only we don't know where it is. So we keep pushing forward.

On Vicarious Causation

Graham Harman

This article gives the outlines of a realist metaphysics, despite the continuing unpopularity of both realism and metaphysics in the continental tradition. Instead of the dull realism of mindless atoms and billiard balls that is usually invoked to spoil all the fun in philosophy, I will defend a weird realism. *This model features a world packed full of ghostly real objects signaling to each other from inscrutable depths, unable to touch one another fully. There is an obvious link here with the tradition known as occasionalism, the first to suggest that direct interaction between entities is impossible. There is another clear link with the related sceptical tradition, which also envisions objects as lying side-by-side without direct connection, though here the objects in question are human perceptions rather than independent real things. Yet this article abandons the solution of a lone magical super-entity responsible for all relations (whether God for Malebranche and his Iraqi forerunners, or the human mind for sceptics, empiricists, and idealists), in favor of a vicarious causation deployed locally in every portion of the cosmos. While its strangeness may lead to puzzlement more than resistance, vicarious causation is not some autistic moonbeam entering the window of an asylum. Instead, it is both the launching pad for a rigorous post-Heideggerian philosophy, and a fitting revival of the venerable problem of communication between substances.*

COLLAPSE II, ed. R. Mackay (Oxford: Urbanomic, March 2007)
ISBN 978-0-9553087-1-2
http://www.urbanomic.com

The phrase 'vicarious causation' consists of two parts, both of them cutting against the grain of present-day philosophy.[1] Causality has rarely been a genuine topic of inquiry since the seventeenth century. The supposed great debate over causation between sceptics and transcendental philosophers is at best a yes-or-no dispute as to whether causal necessity exists, and in practice is just an argument over whether it can be known. What has been lacking is active discussion of the very nature of causality. This is now taken to be obvious: one object exerts force over another and makes it change physical position or some of its features. No one sees any way to speak about the interaction of fire and cotton, since philosophy remains preoccupied with the sole relational gap between humans and the world – even if only to deny such a gap. Inanimate relations have been abandoned to laboratory research, where their metaphysical character is openly dismissed. To revive causation in philosophy means to reject the dominance of Kant's Copernican Revolution and its single lonely rift between people and everything else. Although I will claim that real objects do exist beyond human sensual access to them, this should not be confused with Kant's distinction between phenomena and noumena. Whereas Kant's distinction is something endured by humans alone, I hold that one billiard ball hides from another no less than the ball-in-itself hides from humans. When a hailstorm smashes vineyards or sends waves through a pond, these relations are just as worthy of philosophy as the unceasing dispute over the chasm or non-chasm between being and thought. Neither Kant, nor Hegel, nor their more up-to-date cousins have anything to say about the collision of balls-in-themselves. In the past century, the doctrine of Parmenides that being and thought are the same has been implied by Husserl, stated explicitly by Heidegger, and restated quite emphatically by Badiou. But this equation of being and thought must be rejected, since it leaves us stranded in a human–world coupling that merely reenacts the breakthroughs of yesteryear. To revive the problem of causation means to break free of the epistemological deadlock and reawaken the metaphysical question of what relation means. Along with causation there is also the 'vicarious' part of the phrase, which indicates that relations never directly encounter the autonomous reality of their components. After thousands of years, 'substance' is still the best name for such reality. The widespread resistance to substance is nothing more than revulsion at certain inadequate models of substance, and such models can be replaced. Along with substance, the term 'objects' will be used to refer to autonomous realities of any kind, with the added advantage that this term also makes room for the temporary and artificial objects too often excluded from the ranks of substance.

---

[1] The term was first introduced in my book *Guerrilla Metaphysics: Phenomenology and the Carpentry of Things* (Chicago: Open Court, 2005).

Since this article rejects any privilege of human access to the world, and puts the affairs of human consciousness on exactly the same footing as the duel between canaries, microbes, earthquakes, atoms, and tar, it may sound like a defense of scientific naturalism that reduces everything to physical events. But the term 'vicarious' is designed to oppose all forms of naturalism, by indicating that we still have no idea how physical relations (or any other kind) are possible in the first place. For as I will contend, objects hide from one another endlessly, and inflict their mutual blows only through some vicar or intermediary. For several centuries, philosophy has been on the defensive against the natural sciences, and now occupies a point of lower social prestige and, surprisingly, narrower subject matter. A brief glance at history shows that this was not always the case. To resume the offensive, we need only reverse the long-standing trends of renouncing all speculation on objects and volunteering for curfew in an ever-tinier ghetto of solely human realities: language, texts, political power. Vicarious causation frees us from such imprisonment by returning us to the heart of the inanimate world, whether natural or artificial. The uniqueness of philosophy is secured, not by walling off a zone of precious human reality that science cannot touch, but by dealing with the same world as the various sciences but in a different manner. In classical terms, we must speculate once more on causation while forbidding its reduction to efficient causation. Vicarious causation, of which science so far knows nothing, is closer to what is called formal cause. To say that formal cause operates vicariously means that forms do not touch one another directly, but somehow melt, fuse, and decompress in a shared common space from which all are partly absent. My claim is that two entities influence one another only by meeting on the interior of a third, where they exist side-by-side until something happens that allows them to interact. In this sense, the theory of vicarious causation is a theory of the molten inner core of objects – a sort of plate tectonics of ontology.

1. Two Kinds of Objects

While the phenomenological movement of Husserl and Heidegger did too little to overcome the idealism of the previous cluster of great philosophers, they and their descendants often show a novel concern with specific, concrete entities. Mailboxes, hammers, cigarettes, and silk garments are at home in phenomenology in a way that was never true for the earlier classic figures of German thought. Even if Husserl and Heidegger remain too attached to human being as the centerpiece of philosophy, both silently raise objects to the starring role, each in a different manner. While Husserl bases his system on intentional or ideal objects (which I will rechristen sensual objects), Heidegger restores real objects to philosophy through his famous tool-analysis. It is seldom realized that these two types of objects are both different and complementary. The interplay between real and sensual objects, if taken seriously, provides ontology with a radical new theme.

In the tool-analysis of Heidegger, which fascinates his opponents no less than his allies, we find perhaps the most enduring insight of twentieth century philosophy. Our primary relationship with objects lies not in perceiving or theorizing about them, but simply in relying on them for some ulterior purpose. This first step is useful enough, but misses the essence of Heidegger's breakthrough, which even he never quite grasps. If we remain at this stage, it might seem that Heidegger merely claims that all theory is grounded in practice, that we need to have an everyday relationship with leopards or acids before staring at them or developing a science of them. But notice that even our practical relation to these objects fails to grasp them fully.

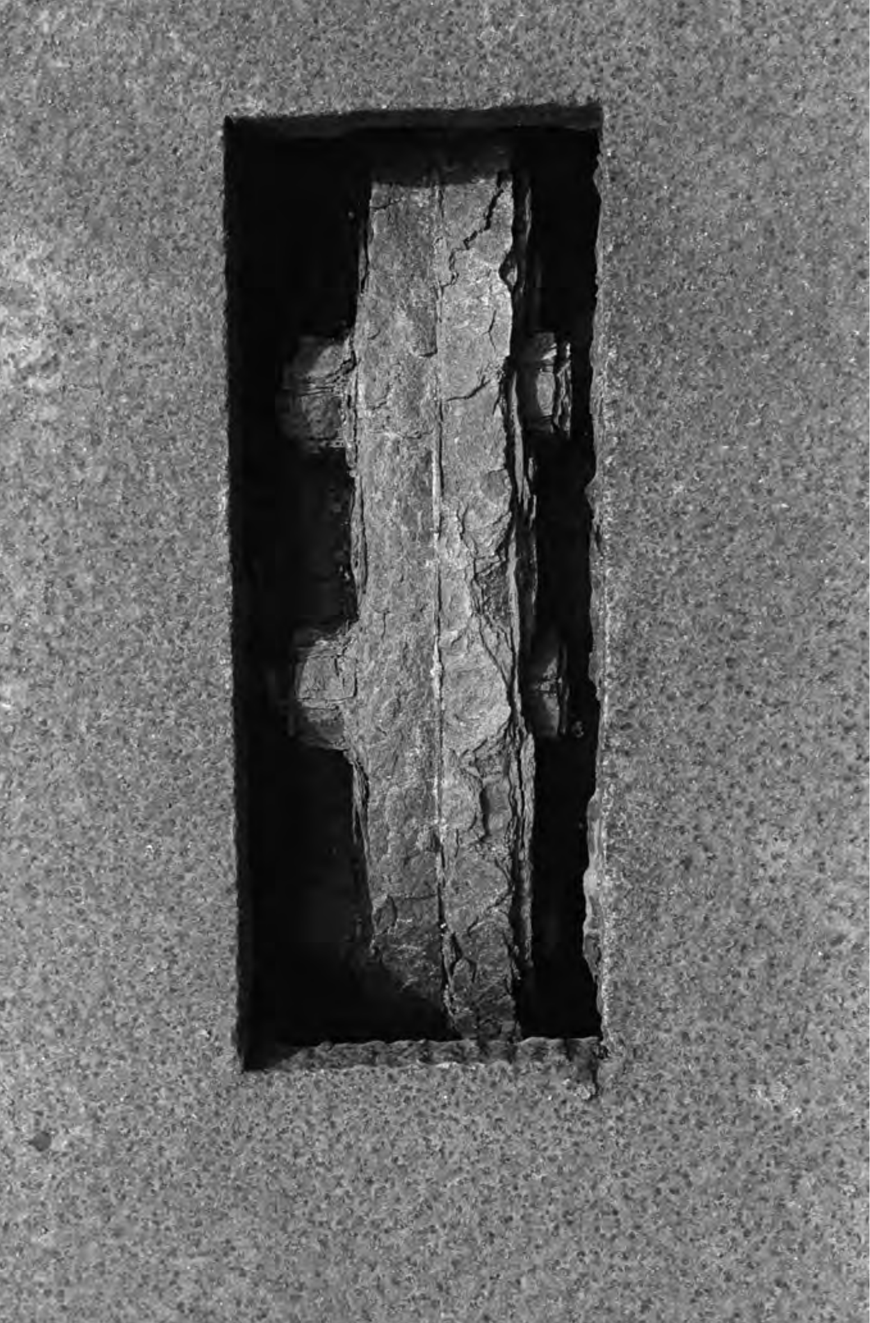
The tribesman who dwells with the godlike leopard, or the prisoner who writes secret messages in lemon juice, are no closer to the dark reality of these objects than the theorist who gazes at them. If perception and theory both objectify entities, reducing them to one-sided caricatures of their thundering depths, the same is true of practical manipulation. We distort when we see, and distort when we use. Nor is the sin of caricature a merely human vice. Dogs do not make contact with the full reality of bones, and neither do locusts with cornstalks, viruses with cells, rocks with windows, nor planets with moons. It is not human consciousness that distorts the reality of things, but relationality *per se*. Heidegger's tool-analysis unwittingly gives us the deepest possible account of the classical rift between substance and relation. When something is 'present-at-hand,' this simply means it is registered through some sort of relation: whether perceptual, theoretical, practical, or purely causal. To be 'ready-to-hand' does not mean to be useful in the narrow sense, but to withdraw into subterranean depths that other objects rely on despite never fully probing or sounding them.[2] When objects fail us, we experience a negation of their accessible contours and become aware that the object exceeds all that we grasp of it. This predicament gives rise to the theme of vicarious causation. For if objects withdraw from relations, we may wonder how they make contact at all. Heidegger's tool-analysis opens the gates on a strange new realism in which entities flicker vaguely from the ocean floor: unable to make contact, yet somehow managing to do so anyway.

---

[2] For a detailed interpretation of Heidegger's tool-analysis, see my first book *Tool-Being: Heidegger and the Metaphysics of Objects*. (Chicago: Open Court, 2002.)

A different sort of object is the basis for Husserl's philosophy. Despite complicated efforts to save Husserl from charges of idealism, he does confine philosophy to a space of purest ideality. Phenomenology cannot speak of how one object breaks or burns another, since this would deliver the world to the power of scientific explanation, which employs nothing but naturalistic theories. For Husserl, the only rigorous method is to describe how the world is given to consciousness prior to all such theories. Philosophy becomes the study of phenomena, not real objects. But phenomena are objects nonetheless: in a new, ideal sense. For what we experience in perception is not disembodied qualities, as the empiricists hold; instead, we encounter a world broken up into chunks. Trees, mailboxes, airplanes, and skeletons lie spread before us, each of them inducing specific moods and sparkling with various subordinate qualities. Since we are speaking solely of the phenomenal realm, it does not matter if these things are hallucinations; even delusions perform the genuine labor of organizing our perception into discrete zones. Note already that sensual objects have a different fate from real ones. Whereas real zebras and lighthouses withdraw from direct access, their sensual counterparts do not withdraw in the least. For here is a zebra before me. Admittedly, I can view it from an infinite variety of angles and distances, in sadness and exultation, at sunset or amidst driving rain, and none of these moments exhaust all possible perceptions of it. Nonetheless, the zebra is already there for me as a whole in all its partial profiles; I see right through them and look to it as a unified object. Although some specific visual or conceptual profile of the zebra is needed for us to experience it, the unified sensual zebra lies at a deeper level of perception than these transient, mutable images. Each sensual profile is encrusted onto the unified zebra-object like a patina of brine. Whereas real objects withdraw, sensual objects lie directly before us, frosted over with a swirling, superfluous outer shell. But this difference seems to give sensual objects the opposite causal status of real ones. Given that real objects never touch directly, their causal relations can only be vicarious. But sensual objects, far from being withdrawn, exist side by side in the same perceptual space from the outset, since we encounter numerous phenomena simultaneously. This presents the contrary problem to vicarious causation: namely, why do all the phenomena not instantly fuse together into a single lump? There must be some unknown principle of blockage between them. If real objects require vicarious causation, sensual objects endure a buffered causation in which their interactions are partly dammed or stunted.

The situation is perplexing, but the general path of this article is already clear. Real objects withdraw into obscure cavernous underworlds, deprived of causal links. Sensual objects, by contrast, are so inclined to interact with their neighbors that we wonder why they fail to do so at every instant. In other words, the only place in the cosmos where interactions occur is the sensual, phenomenal realm. Against philosophies that regard the surface as formal or sterile and grant causal power only to shadowy depths, we must defend the opposite view: discrete, autonomous form lies only in the depths, while dramatic power and interaction float along the surface. All relationships are



superficial. For this reason, we must discover how real objects poke through into the phenomenal realm, the only place where one relates to another. The various eruptions of real objects into sensuality lie side by side, buffered from immediate interaction. Something must happen on the sensual plane to allow them to make contact, just as corrosive chemicals lie side by side in a bomb – separated by a thin film eaten away over time, or ruptured by distant signals.

2. A JIGSAW PUZZLE

It is well known that Husserl emphasizes the intentionality of consciousness. We are always conscious of something, always focused on a particular house, pine tree, beach ball, or star, and indeed on many such objects at once. It is not widely known that Husserl also stumbles across the fateful paradox that intentionality is both one and two. For in a first sense, my encounter with a pine tree is a unified relation; we can speak of the encounter as a whole, and this whole resists exhaustive description. But in another sense, I clearly do not fuse with the tree in a single massive lump; it remains distinct from me in the perception. This gives the strange result that in my intention of the tree, we both inhabit the interior of the total intentional relation. This seemingly dry observation by Husserl has not sparked much interest in his readers. Even so, if combined with Heidegger's insight into the withdrawal of real objects behind all relations, it provides all the pieces of a new philosophy.

To repeat, the pine tree and I are separate objects residing on the interior of a third: the intention as a whole.

But there is a fascinating asymmetry between the members of this trio. We cannot fail to notice that of the two objects living in the core of the third, I am a real object but the pine tree merely a sensual one. The I sincerely absorbed in the things it perceives is not the I as seen by others, but rather the real I, since my life actually consists at this moment in being occupied by these phenomena, not in being a sensual object for the gaze of others or even for myself. By contrast, the real pine tree does not inhabit the intention, since the real tree (assuming there is such a thing) lies outside any relation to it, withdrawing into depths never entered by outsiders. Finally, the intention as a whole must be classed as a real object rather than a sensual one: for even if my intention of the tree is the most depraved hallucination, the intention itself is in fact underway, quite apart from whether it relates to anything outside. To summarize, we have a real intention whose core is inhabited by a real me and a sensual pine tree. In addition, there is also a withdrawn real tree (or something that we mistake for one) lying outside the intention, but able to affect it along avenues still unknown. Finally, the sensual tree never appears in the form of a naked essence, but is always encrusted with various sorts of noise. Elsewhere I have called it 'black noise', to emphasize that it is highly structured, not the sort of formless chaos suggested by the 'white noise' of television and radio.[3] Black noise initially seems to come in three varieties. First, the sensual tree has pivotal or essential qualities that must always belong to it under penalty of the intentional agent no longer considering it the same thing. Second, the tree has accidental features shimmering along its surface from moment to moment, not affecting our identification of it as one and the same. Finally, the pine tree stands in relation to countless peripheral objects that inhabit the same intention (neighboring trees, mountains, deer, rabbits, clouds of mist).

---

[3] *Guerrilla Metaphysics*, 183 ff.

We should also note five distinct sorts of relations between all these objects:

1. CONTAINMENT. The intention as a whole contains both the real me and the sensual tree.

2. CONTIGUITY. The various sensual objects in an intention lie side by side, not affecting one another. Only sometimes do they fuse or mix. Within certain limits, any sensual object's neighbors can be shuffled and varied without damaging the identity of that object, as when drifting mists do not interfere with my focus on the tree.

3. SINCERITY. At this very moment I am absorbed or fascinated by the sensual tree, even if my attitude toward it is utterly cynical and manipulative. I do not contain the sensual tree, because this is the role of the unified intention that provides the theater of my sincerity without being identical to it. And I am not merely contiguous with the tree, because it does in fact touch me in such a way as to fill up my life. I expend my energy in taking the tree seriously, whereas the sensual tree cannot return the favor, since it is nothing real.

4. CONNECTION. The intention as a whole must arise from a real connection of real objects, albeit an indirect connection. After all, the other possible combinations yield entirely different results. Two sensual objects merely sit side by side. And my sincere absorption with trees or windmills is merely the interior of the intention, not the unified intention itself. Hence, a real object itself is born from the connection of other real objects, through unknown vicarious means.

5. No relation at all. This is the usual state of things, as denied only by fanatical holists, those extremists who pass out mirrors like candy to every object that stumbles down the street. Real objects are incapable of direct contact, and indeed many have no effect on one another at all. Even the law of universal gravitation only applies among a narrow class of physical objects, and even then concerns a limited portion of their reality. And in a different case, the sensual tree has no relation to me at all, even though I am sincerely absorbed by it. The oxygen I breathe comes from the real tree, not from my perception of it. The sensual tree is a phantasm surviving only at the core of some intention, and takes up no independent relations even with its contiguous phantoms. They are only related vicariously, through me, insofar as I am sincerely absorbed with both.

The objects populating the world always stand to each other in one of these five relations. In *Guerrilla Metaphysics*, I suggested that causation is always vicarious, asymmetrical, and buffered. 'Vicarious' means that objects confront one another only by proxy, through sensual profiles found only on the interior of some other entity. 'Asymmetrical' means that the initial confrontation always unfolds between a real object and a sensual one. And 'buffered' means that I do not fuse into the tree, nor the tree into its sensual neighbors, since all are held at bay through unknown firewalls sustaining the privacy of each. From the asymmetrical and buffered inner life of an object, vicarious connections arise occasionally (in both senses of the term), giving birth to new objects with their own interior spaces. There is a constant meeting of asymmetrical partners on the interior of some unified object: a real one meeting the sensual vicar or deputy of another. Causation itself occurs when these obstacles are somehow broken or suspended. In seventeenth-century terms, the side-by-side proximity of real and sensual objects is merely the occasion for a connection between a real object inside the intention and another real object lying outside it. In this way, shafts or freight tunnels are constructed between objects that otherwise remain quarantined in private vacuums.

We now have five kinds of objects (real intention, real I, real tree, sensual tree, sensual noise) and five different types of relations (containment, contiguity, sincerity, connection, and none). Furthermore, we also have three adjectives for what unfolds inside an object (vicarious, asymmetrical, buffered) and three different kinds of noise surrounding a sensual object (qualities, accidents, relations). While this may not be an exhaustive census of reality, and may eventually need polishing or expansion, it offers a good initial model whose very strictness will help smoke out those elements it might have overlooked. What remains to be seen is how these elements interact, how one type of relation transforms into another, how new real objects paradoxically arise from the interaction between real objects and sensual ones, and even how sensual objects manage to couple and uncouple like spectral rail cars. These sorts of problems are the subject matter of object-oriented philosophy: the inevitable mutant offspring of Husserl's intentional objects and Heidegger's real ones. In turn, these are only the present-day heirs of Hume's contiguous impressions and ideas (Husserl) and the disconnected objects of Malebranche and his Ash'arite predecessors (Heidegger).

The problem of philosophy now resembles a jigsaw puzzle. We have detected the pieces as carefully as possible, and none seem to be blatantly missing. We also have a picture of what the ultimate solution should look like: the world as we know it, with its various objects and interactions. Unlike jigsaw puzzles, this one unfolds in at least three dimensions, ceaselessly changing from moment to moment. But like such puzzles, instead of mimicking the original image, it is riddled with fissures and strategic overlaps that place everything in a new light. Like five-year-olds faced with a massive thousand-piece puzzle, our greatest danger lies in becoming discouraged. But whereas frustrated children angrily throw their pieces to the floor and change activities, we remain trapped in our puzzle from the start, since it is the very enigma of our world. Philosophers can escape it only through insanity, or with the aid of rope or a revolver.

3. ONTOLOGY AND METAPHYSICS

Beginners in philosophy often ask the exact difference between ontology and metaphysics. In fact there is no consistent distinction, since each philosopher redefines these terms to suit individual purposes. For Heidegger, ontology is the account of how being is revealed to

humans, while metaphysics remains a term of insult for philosophies that explain all beings in terms of some privileged entity. For Levinas, ontology belongs to the global war between beings, while metaphysics speaks of the infinite otherness that lies beyond such conflict. For my own part, I have generally used these terms interchangeably for a realist position opposed to all human-centered philosophies; at times such flexibility remains useful, as in the opening section of this article. Yet I would also like to propose a more exact difference between them, one not unrelated to their classical distinction. Henceforth, let 'ontology' refer to a description of the basic structural features shared by all objects, and let 'metaphysics' signify the discussion of the fundamental traits of specific types of entities. In this sense, the aforementioned puzzle-pieces belong solely to ontology, since no object is exempt from their rule. These include the basic opposition between real and sensual objects, the five types of relation between them, and the bondage of sensual objects to their various qualities, accidents, and relations. Time and space also belong to ontology, since even eternal and non-spatial objects elude only the narrowly physical spatio-temporal realm, and by no means escape time and space in a broader sense. The question of universals also seems to be a global theme belonging to ontology as a whole, and there may be others. As for metaphysics, which walls off and analyzes the internal organs of any specific kind of entity, the most obvious possible topics include human being, language, artworks, and even God. Any type of object distinct from others, however hazy the boundaries may be, can become the subject of a metaphysics. There could be a metaphysics of artworks, the psyche, and language, and even of restaurants, mammals, planets, teahouses, and sports leagues. Insofar as philosophy clearly differs from activities such as singing and gambling, there could also be a metaphysics of philosophy itself, unlocking the crucial features of this discipline, whatever its numerous variations and degenerate sophistical forms.

The distinction between ontology and metaphysics is proposed here for a specific reason. Along with real objects, we have also described sensual objects, which exist only on the interior of some intentional whole. Yet intentionality is regarded by almost everyone as a narrowly human feature. If this depiction were correct, sensual objects would be confined to a metaphysics of human perception, with no place in an ontology designed to address plastic and sand dunes no less than humans. This confinement of sensuality to the human kingdom must be refused. Intentionality is not a special human property at all, but an ontological feature of objects in general. For our purposes, intentionality means sincerity. My life is absorbed at any moment with a limited range of thoughts and perceptions. While it is tempting to confuse such absorption with 'conscious awareness,' we need to focus on the most rudimentary meaning of sincerity: contact between a real object and a sensual one. For instance, I may be sincerely absorbed in contemplating glass marbles arranged on the surface of a table. This is my sincerity at the moment, since I forego other possibilities of greater and lesser import to witness this austere, Zen-like spectacle. But note that the glass marbles themselves are sincerely absorbed in sitting on the table, rather than melting in a furnace or hurtling through a mineshaft. (Though they may not be ‘marbles’ for anyone but humans or playful kittens, we need a nickname for the united object that we draw into our games.) The question for us is not the panpsychist query of whether these marbles have some sort of rudimentary thinking and feeling capacities, but whether they as real objects encounter the table-surface as a sensual one.

The answer is yes. We must ignore the usual connotations of sensuality and fix our gaze on a more primitive layer of the cosmos. It is clear that the marbles must stand somewhere in reality, in contact with certain other entities that stabilize them briefly in one state or another. The entities they confront cannot be real objects, since these withdraw from contact. Nor can the marbles run up against free-floating sensual qualities, for in the sensual realm qualities are always attached to objects. Only one alternative remains: the marbles are sincerely absorbed with sensual objects. This indirect argument becomes more persuasive if we examine the landscape inhabited by the marbles, which turns out to share the basic structural features of human intentionality. First, notice that these marbles are perfectly capable of distinguishing between the table and the contiguous relational environment, even if not in the panpsychist sense of a primitive judging ability. At present the marbles sit on the table, but are otherwise surrounded by air; hence, this air is contiguous with the tabletop in the life of each marble. But if we now carefully frame the marbles with bookends or melted wax, the table itself remains the same intentional object, unaffected by our eccentric manipulations. Second, the marble confronts the tabletop quite apart from its accidental coldness and slickness, though it probably registers these features in some way as well. If we heat the tabletop, or render its surface sticky or granulated by pouring different materials nearby, the table as an intentional object still remains the same. The final question is whether the marbles can make a distinction between the table and its more essential qualities, such as its hardness, levelness, solidity, and lack of perforation. Even humans can only make this distinction between objects and their qualities in very special cases; since I will soon describe these cases under the heading of 'allure', we should wait to ask whether glass marbles are able to follow suit. What is already evident is that all real objects inhabit a landscape of sensual ones, a playground whose fluctuations enable new real connections to arise. Some of these fluctuations are a mere domestic drama, while others provoke new relations with the outside. But whatever is special about human cognition belongs at a more complicated level of philosophy than these sensual objects, though it must be expressible in terms of them.

Elsewhere I have used the phrase 'every relation is itself an object', and still regard this statement as true. But since this article has redefined relations to include containment, sincerity, and contiguity, the slogan must be reworded as follows: 'every connection is itself an object.' The intentional act's containment of me does not make the two of us into a new object, and neither (for the most part) do two or three nearby perceptions of cars make a unified object. But two vicariously linked real objects do form a new object, since they generate a new internal space. When two objects give rise to a new one through vicarious connection, they create a new unified whole that is not only inexhaustible from the outside, but also filled on the inside with a real object sincerely absorbed with sensual ones. And just as every connection is an object, every object is the result of a connection. The history of this connection remains inscribed in its heart, where its components are locked in a sort of kaleidoscopic duel. But connections occur only between two real objects, not any other combination. This entails that my relation to the sensual pine tree is not itself an object, but simply a face-off between two objects of utterly different kinds. Hence, although intentionality seems to be a relation between me and the sensual pine tree, this is merely its interior. The intention itself results only from the unexplained vicarious fusion of me with the real pine tree, or with whatever engenders my deluded belief that I perceive one.

To repeat, my relation with the sensual pine tree is not a full-blown connection, but only a sincerity. This sincerity can indeed be converted into an object, as happens in the analysis of our own intentions or someone else's. When I analyze my relation to the sensual tree, I have converted that relation into an object for the first time. It has become a real object insofar as its exact nature recedes from view, inexhaustible no matter how many analyses I perform. We now face a merely sensual apparition of the original sincere relation, which withdraws from analysis just as hammers withdraw from handling. A second, more tedious observer might now decide to perform an analysis of my analysis, thereby converting it into an object whose nature can never be grasped, and so on to infinity. But note that this is not an infinite regress: all of these objects are not contained infinitely in the situation from the outset, but are sequentially produced *ad nauseum* by an increasingly twisted and pedantic series of analysts. Back in stage one, even my relation to the sensual pine tree is not a real object, but simply a sincere relation of two distinct elements inside a larger one. Unified objects can be molded at will from that clay-like interior. This already shows a way for sincere relations to be converted into real connections. Whether it is the only such way, and whether this method belongs to humans alone, is still unclear.

Another point is in order before passing to the final section. To say that every object is located on the sensual molten core of another object undermines some of the key assumptions of Heidegger. For him, human being partially transcends other beings, rising to glimpse them against a background of nothingness. But the interior of an object leaves no room for transcendence or even distance: a horse seen in a valley several miles away still touches me directly insofar as I witness it. Distance lies not in the sphere of perception, where everything brushes me directly with greater or lesser intensity, but only between the mutually exclusive real objects that lie beyond perception. We do not step beyond anything, but are more like moles tunneling through wind, water, and ideas no less than through speech-acts, texts, anxiety, wonder, and dirt. We do not transcend the world, but only descend or burrow towards its numberless underground cavities – each a sort of kaleidoscope where sensual objects spread their colours and their wings. There is neither finitude nor negativity in the heart of objects. And each case of human mortality is just one tragic event among trillions of others, including the deaths of house pets, insects, stars, civilizations, and poorly managed shops or universities. The Heidegger-Blanchot death cult must be expelled from ontology, and perhaps even from metaphysics.

4. ALLURE AND CAUSATION

Some may find it disturbing to think of the world as made up of vacuum-sealed objects, each with a sparkling phenomenal interior invaded only now and then by neighboring objects. A more likely problem, however, is indifference. There seems to be no need for such a weird vision of reality, since it is easy enough to think of the world as made of brute pieces of inescapable solid matter: 'primary qualities' supporting a series of more dashing, volatile human projections. In my view, however, Heidegger has rendered this picture of the world obsolete. Though his tool-analysis aims to describe only the withdrawal of objects behind explicit human awareness, practical activity is equally unable to exhaust the depth of objects, and even causal relations fail to let them encounter one another in full.[4] Finally, even sheer physical presence in space is a concept shaken to the core by the tool-analysis: after all, to occupy a spatial position is to take up relations, and however objects might occupy space, their reality is something deeper. The world is neither a grey matrix of objective elements, nor raw material for a sexy human drama projected onto gravel and sludge. Instead, it is filled with points of reality woven together only loosely: an archipelago of oracles or bombs that explode from concealment only to generate new sequestered temples. The language here is metaphorical because it must be. While analytic philosophy takes pride in never suggesting more than it explicitly states, this procedure does no justice to a world where objects are always more than they literally state. Those who care only to generate arguments almost never generate objects. New objects, however, are the sole and sacred fruit of writers, thinkers, politicians, travellers, lovers, and inventors.

---

[4] The idea that physical relations also have an intentional structure is a minority view, but by no means my own invention. See for instance George Molnar's fascinating *Powers: A Study in Metaphysics* (Oxford: Oxford University Press, 2003) 60 ff.

Along with the distinction between real and sensual objects, there were five possible kinds of relations between them: containment, contiguity, sincerity, connection, and none. Our goal is to shed some light on the origin of connection, the one relation of the five that seems most troubling for a theory of ghostly, receding objects. A connection simply exists or fails to exist; it is a purely binary question. Furthermore, connection must be vicarious, since one purely naked object always recedes from another. An object simply exists, and this existence can never fully be mirrored in the heart of another. What we seek is some fertile soil of relation from which connections surge up into existence: a type of relation able to serve as the engine of change in the cosmos. 'Connection' itself cannot provide the solution, since this is precisely what we are trying to explain; if two objects are connected, then the labour we wish to observe is already complete. The option 'no relation at all' also fails to help, since if things are unrelated then they will remain so, as long as the intermediary we seek is lacking. 'Containment' is of no assistance either. Here too we have a merely binary question: either the sensual pine tree and I are together inside a given intention, or we are not. Finally, 'contiguity' does not give us what we need: at best, the shifting play of sensual objects redistributes the boundaries between them, but cannot lead to real changes outside their molten internal homeland. The only remaining option is 'sincerity.' This must be the site of change in the world. A real object resides in the core of an intention, pressed up against numerous sensual ones. Somehow, it pierces their colored mists and connects with a real object already in the vicinity but buffered from direct contact. If light can be shed on this mechanism, the nature of the other four types of relation may be clarified as well.

It all comes down to the dynamics of sincerity, whether of a human or any other real object. Sincerity contends with sensual objects that are defined by their qualities and shrouded with peripheral accidents and relations. What we seek is the manner in which sincere relation with a sensual object is transformed into direct connection with a real one. The coupling and uncoupling of real and sensual objects is now our central theme. We know that a sensual object is detachable from its accidents and relations. The interesting question is whether it can also be detached from its qualities, which seem to belong to it more intimately. By qualities I mean the essential qualities, without which we would regard an object as no longer the same thing. Remember, there is no hand-wringing crisis of objectivity here, since we are speaking of qualities that belong not to the essence of a real object, but only to the sensual things that command our attention – a realm where we ourselves are the highest judge in the land. Now, it might be

imagined that we could liberate the qualities of the marbles by overtly discovering and listing all the crucial features that the marbles cannot do without. This was the great hope of Husserl's method of eidetic variation. But the effect of this procedure is superficial, and does not grasp the sensual marbles in their essence. Notice that even as our analysis of these objects proceeds, we continue to take them seriously as units, even if we brilliantly slice them into thousands of separate features. Even in the case of a sensual object, the essential qualities cannot be stated or analyzed without becoming something like accidents: free-floating traits artificially detached from the sensual object as a whole. Our sincerity is not really concerned with such a list of detached features, as Husserl realizes when he grants privilege to unified sensual objects over their myriad facets. The unity of such objects even indicates that there is just one quality at issue: this marble-essence, this pine-essence. The unified quality of the thing is not noise at all, but is the sensual object itself. Concerning Aristotle's question as to whether a thing is identical with its essence, the answer for sensual objects is yes. Although qualities were described as a form of noise earlier in this article, this is true only insofar as they veer off toward the status of accidents, when broken free and itemized separately. But the existence of a unified quality of things means that the sensual realm is already home to a certain 'I know not what' that makes the marble a steady focus of my attention. Unlike the followers of Locke, we do not say *je ne sais quoi* in a spirit of gentle mockery, but as a true statement about sensual objects. The sensual thing itself has a unified and basically ineffable effect on us, one that cannot be reduced to any list of traits. But if such listing of traits does not sever a thing from its quality, there may be another way for this to happen. We have also seen that vicarious causation – the enchanted unicorn we seek – requires contact with the essential qualities of a thing without contact with the thing as a whole. In this way, discovery of how the sensual object splits from its quality may be a stepping-stone toward discovering an analogous event among real objects.

The separation between a sensual object and its quality can be termed 'allure.'[5] This term pinpoints the bewitching emotional effect that often accompanies this event for humans, and also suggests the related term 'allusion,' since allure merely alludes to the object without making its inner life directly present. In the sensual realm, we encounter objects encrusted with noisy accidents and relations. We may also be explicitly aware of some of their essential qualities, though any such list merely transforms the qualities into something accident-like, and fails to give us the unified bond that makes the sensual thing a single thing. Instead, we need an experience in which the sensual object is severed from its joint unified quality, since this will point for the first time to a real object lying beneath the single quality on the surface. For humans, metaphor is one such experience. When the poet writes 'my heart is a furnace,' the sensual object known as a heart captures vaguely defined furnace-qualities and draws them haltingly into its orbit. The inability of the heart to fuse easily with furnace-traits (in contrast with literal statements such as 'my heart is the strongest muscle in my body') achieves allusion to a ghostly heart-object lying beneath the overly familiar sensual heart of everyday acquaintance. Notice that the inverse metaphor is entirely asymmetrical to the first: 'the furnace is a heart' draws cardiac traits into the orbit of a sensual furnace, which is freed from bondage to its usual features and evoked as a sort of hidden furnace-soul, one whose *animus* now powers rhythmic beating and circulation. Humour does something similar: we can follow Bergson's *On Laughter* and note the tension between a comic dupe and the traits he no longer freely adapts to changing circumstances. These qualities are now exposed as a discrete visible shell beneath which the agent haplessly fails to control them. There are countless examples of allure. In instances of beauty, an object is not the sum total of beautiful colors and proportions on its surface, but a kind of soul animating the features from within, leading to vertigo or even hypnosis in the witness. When Heidegger's hammer fails, a concealed hammer-object seems to loom from the darkness, at a distance from its previously familiar traits. In language, names call out to objects deeper than any of their features; in love, the beloved entity has a certain magic hovering beneath the contours and flaws of its accessible surface. The list of possibilities is so vast that they deserve to be categorized in some encyclopedic work of aesthetics. Until now, aesthetics has generally served as the impoverished dancing-girl of philosophy – admired for her charms, but no gentleman would marry her. Yet given the apparently overwhelming scope of allure, aesthetics may deserve a rather vast role in ontology.

---

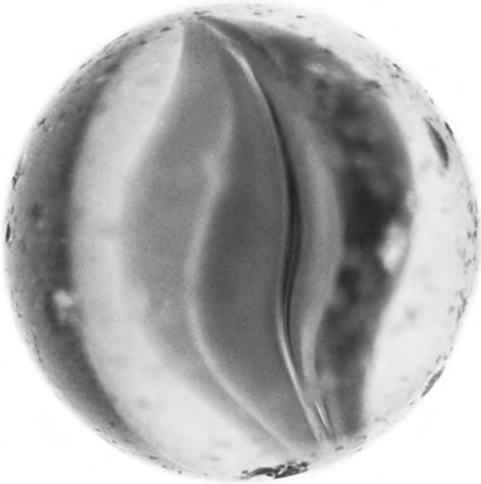
[5] See also *Guerrilla Metaphysics*, 142-4.

Different sensual objects within the same intention are described as contiguous; they do not melt together, but are treated by the intentional agent as distinct, and this agent is the final court of appeal in the sensual realm. This pertains to what has been termed the relations of sensual objects. But accidents are a different case. The surface of a sensual object does not merely lie side-by-side with it. Even though we look straight through these accidents to stay fixed on the underlying sensual thing, the accidents are not viewed as separate from that thing, but are encrusted onto it. This frosting-over with peripheral qualities comes about in an interesting way. Recall that the sensual tree as a whole is made up of just one quality (the one from which it is severed in allure). But notice that this unified tree-apparition still has parts. If we start taking away branches and leaves, there will come a point at which we no longer regard it as the same tree; the tree is dependent on its parts. Yet these parts are only unified in the tree along one specific path. It never devours them completely, but employs only a limited portion of their reality. What we know as the accidents of the sensual tree are simply the remainder of its parts, the remnant not deployed in the new object. Each of these parts is complicated because it is made up of further parts, and so on to infinity. But however far we advance toward this infinity, we continue to find objects, not raw sense data. It would be wrong to think that we confront a field of colour-pixels and then mold them into objective zones. For in the first place, it is arbitrary to think that points of green are more qualitatively basic than a unified tree-quality or branch-quality; all are capable of filling up my sincerity, and all have a specific personal style. And in the second place, even a supposed pixel of green at least takes the spatial form of a dot, and hence is a complicated object in its own right. There are always largest objects in the sensual realm: namely, those that are recognized by sincerity at any moment. But one cannot find a smallest, since there will always be a leftover remainder of parts, and parts of parts, like the endless overtones of notes struck on a piano. These accidents are the only possible source of change, since they alone are the potential bridge between one sensual object and another. For there can be no changes in the sensual object itself, which is always a recognized *fait accompli*; at most, it can be eliminated and replaced by a new one. Accidents alone have the dual status of belonging and not belonging to an object, like streamers on a maypole, or jewels on a houka. Accidents are tempting hooks protruding from the sensual object, allowing it the chance to connect with others and thereby fuse two into one.

But the relation of part and whole does not occur only in the sensual realm. A real object, too, is formed of parts whose disappearance threatens its very existence.

The difference is that the parts of a sensual object are encrusted onto its surface: or rather, certain aspects of those parts are fused to create it, while the remainder of those parts emanates from its surface as noise. By contrast, the parts of a real object are contained on the interior of that object, not plastered onto its outer crust. In both cases, however, there is a vicarious cause enabling the parts to link together. This can be clarified through the historical difference between scepticism and occasionalism, which are complementary in the same manner as encrustation and connection. Hume and Malebranche face opposite versions of the same problem. Although Hume supposedly doubts the possibility of connection, note that for him a connection has actually already occurred: he is never surprised that two billiard balls lie simultaneously in his mind, but doubts only that they have independent force capable of inflicting blows on each other. In this sense, Hume actually begins with connection inside experience and merely doubts any separation outside it. Conversely, Malebranche begins by assuming the existence of separate substances, but doubts that they can occupy a shared space in such a way as to exchange their forces – leading him to posit God's power as the ultimate joint space of all entities. Like Hume, we can regard the intentional agent as the vicarious cause of otherwise separate phenomena. The tree and its mountainous backdrop are indeed distinct, yet they are unified insofar as I am sincerely absorbed with both. But more than this: when the parts of the tree fuse to yield the tree with its single fixed tree-quality, I too am the vicarious cause for the connection of these sensual objects. Even if I merely sit passively, without unduly straining eyes or mind, it is still for me that these parts have combined. Here, a real object (I myself) serves as the vicarious cause for two or more sensual ones. In the inverted case of Malebranche, we cannot accept the pistol shot of the deity as our vicarious cause, since no explanation is given of how God as a real object could touch other real objects; fear of blasphemy is the sole protection for this incomplete doctrine. Instead, just as two sensual objects are vicariously linked by a real one, two real objects must be vicariously linked by a sensual one. I make contact with another object, not through impossible contact with its interior life, but only by brushing its surface in such a manner as to bring its inner life into play. Just as only the opposite poles of magnets make contact, and just as the opposite sexes alone are fertile, it is also the case that two objects of the same type do not directly touch one another. Contiguity between sensual objects is impossible without a real intentional agent, and connection between real ones does not occur except by means of a sensual intermediary.

This entails that all contact must be asymmetrical. However deeply I burrow into the world, I never encounter anything but sensual objects, and neither do real objects ever encounter anything but my own sensual facade. The key to vicarious causation is that two objects must somehow touch without touching. In the case of the sensual realm, this happens when I the intentional agent serve as vicarious cause for the fusion of multiple sensual objects: a fusion that remains only partial, encrusted with residual accidents. But in the case of real objects, the only way to touch a real one without touching it is through allure. Only here do we escape the deadlock of merely rolling about in the perfumes of sensual things, and encounter qualities belonging to a distant signalling thing rather than a carnally present one. The only way to bring real objects into the sensual sphere is to reconfigure sensual objects in such a way that they no longer merely fuse into a new one, as parts into a whole, but rather become animated by allusion to a deeper power lying beyond: a real object. The gravitational field of a real object must somehow invade the existing sensual field. Just as I am the vicarious link between two sensual objects, the alluring tree is the vicarious link between me and the real tree. The exact dynamics of this process deserve a lengthier treatment, but something unusual has already become evident. The separation of a thing from its quality is no longer a local phenomenon of human experience, but instead is the root of all relations between real objects, including causal relations. In other words, allure belongs to ontology as a whole, not to the special metaphysics of animal perception. Relations between all real objects, including mindless chunks of dirt, occur only by means of some form of allusion. But insofar as we have identified allure with an aesthetic effect, this means that aesthetics becomes first philosophy.



Demons Get Out!

Interview with Paul Churchland[1]

From his first significant publication in 1970[2] *to the forthcoming* Neurophilosophy at Work[3]*, Paul Churchland has established a reputation as a brilliantly iconoclastic philosopher of mind and science. Along with his wife and frequent collaborator Patricia, Churchland remains the most (in)famous proponent of 'eliminative materialism', whose canonical formulation opens a seminal paper from 1981:*

> *Eliminative materialism is the thesis that our commonsense conception of psychological phenomena constitutes a radically false theory, a theory so fundamentally defective that both the principles and the ontology of that theory will eventually be displaced, rather than smoothly reduced by, completed neuroscience.*[4]

Although this radical claim has certainly tended to provoke consternation among philosophers who have sought to integrate commonsense or 'folk' psychology into the ambit of natural science, the stakes of the eliminativist hypothesis evidently transcend the niceties of academic philosophy, with professional philosophers of mind moved to

depict the promised 'elimination' in apocalyptic terms ('[it] would be, beyond comparison, the greatest intellectual catastrophe in the history of the species').[5] *For Churchland proposes nothing short of a cultural revolution: the reconstruction of our phenomenological self-image in light of a new scientific discourse. In the following conversation Churchland reemphasises his commitment to eliminative materialism, exploring its broad consequences for science and philosophy, and remarking upon key research outcomes and philosophical problems which have influenced its development.*

COLLAPSE: Let's start where the totally ignorant person would start: according to the current entry on *Wikipedia*,[6] Paul Churchland is a philosopher who believes in eliminative materialism, which says that folk psychology should be replaced. Our propositional attitudes can be reduced to neuroscientific language.

PAUL CHURCHLAND: I haven't gone to *Wikipedia* and seen my own entry [!] but somebody else told me that that's the first entry and of course it's strictly true. That paper is a paper I wrote twenty-five years ago! But it's the one that most captured people's attention and as they describe it, in two or three sentences, they are correct. I really am

inclined still, after twenty-five years, to think that our conception of our own cognition will change as we learn more and more about the brain.

What I'm most suspicious of, in our common sense conception, are the so-called 'propositional attitudes' – talk about 'beliefs that *p*', and 'desires that *p*,' and 'fears that *p*' and 'hopes that *p*', and 'preferring that *p* to that *q*', where we describe our mental states in sentences in some language or other. I'm suspicious of that for a number of reasons, and one of them is that we are the only creature on the planet that uses language! And I want to ask the question: How do we account for the cognition of all the other creatures – the dogs and the cats and the mice and the lobsters and eagles and the porpoises and so forth? I doubt very much that they are all talking to themselves in some inner language in the way that we think of ourselves as doing; and because our brains are so similar to theirs, I have to be skeptical about whether our cognition has that form.

Now, of course, that is how I think of *myself*; in terms of propositional attitudes! I am as much in the grip of that conception as is anybody else – and at the moment I don't know of any systematic alternative; one has not been developed yet. But I'm sceptical that propositional attitudes describe more that 2 or 3 percent of human cognition. I would guess the other 97 to 98 percent of cognition has nothing to do with language or the forms, the structures, that you find in language. So I am as sceptical about propositional attitudes as I was twenty-five years ago.

Indeed my scepticism has only grown, because I've learnt more and more, the human race has learnt more and more, about how brains – all brains, not just human brains – how all brains represent the world. And we're learning about an alternative way of describing how brains represent the world; it has to do with population coding. We're learning something about how brains process information. And the answer seems to be that they transform one higher-dimensional vector into another. These models, which are now fifteen to twenty years old, are ever more successful at explaining how we can do interesting things such as recognize faces or recognize voices or [reaching for cup] reach for something that is in front of us.

The neurosciences are making progress, exciting progress, and they're *not* making progress because they're paying attention to 'propositional attitudes'. So, I think that in the long run science may decide that propositional attitudes are not the fundamental mode of cognition of human brains. That's why I'm inclined to think that in the long run science will eliminate them from its basic story of how brains work.

Other parts of human cognition like sensations and emotions, I don't think they'll be eliminated at all, because we are already starting to get neuronal explanations of sensations and what they are and how they work – how the brain codes for color, how the brain codes for pitch of sound, how the brain codes for tastes and smells – and also the emotions, although there it looks like biochemistry will play a larger role, rather than the activities of neurons. The different emotions look like they're connected with different kinds of neuropeptides like oxytocin or adrenalin or other chemicals like that. The brain is a chemical machine as much as it is an electrical machine. And I think those things will be successfully reduced or explained by modern science. In this sense I'm not an eliminativist at all; I'm a reductionist. But I am suspicious about the propositional attitudes still, for what I think are good reasons.

Now, I hope you will realize that the position I just outlined isn't quite as radical as the first two sentences in *Wikipedia* make it sound. I'd like to be thought a radical, but I don't want to be thought *crazy*!

C: So do you still think that folk psychology is a kind of theory?

PC: I do, and I think it will change as we learn more and more. That is the theory, the theoretical framework. The way we talk to one another will change. We already talk to one another about being adrenalized or being depressed because our dopamine levels are down. At least, some of us do. Just as we learned to look at the night sky and see it differently from how Aristotle saw it. He looked up and he saw the inside of a sphere with little jewels stuck on it that turned around us. We look up at the sky and see sort of an infinite space going off to infinity and the stars aren't moving at all, it's the earth that's turning. So this kind of major change in how we perceive or understand something has happened to the human race before, it's just that it's very close to home this time; it's going to be the way we think and talk about *ourselves* …

C: But is folk psychology similar to a physics theory, or is it more like the sort of common knowledge that we have? Let's take the example of picking up my glasses here. It might actually be that a resultant force is acting on them and describes this move. But I would just say 'I'm picking up my glasses.' Is it that kind of relationship that folk psychology might have to the more basic scientific theory? The kind that common-language claims would have to a physics theory?

PC: I think that the analogy is a good one. People talk about 'folk physics'. And the physics of Aristotle, if you go back two-thousand-some years, describe pretty much what folk physics thinks, and most people today still think in terms of folk physics. But physicists don't, and people who've learnt some physics see the world interestingly differently. And I think the same will be true of folk psychology; Anyone who learns a great deal of neuroscience – especially cognitive neuroscience, high level systems neuroscience – will understand the people around them in interestingly different ways.

And I don't think of this as being cold and machine-like, or something frightening, something from science fiction that you want to run away from! I think of it as just the reverse. If you have a much deeper understanding of how brains work, and how they function well when they do well, and how they function badly when they do badly, then we'll be able to see in other people when things are going wrong! You can *see* that someone is not being cruel, they're depressed for some reason and they're having a hard time dealing with the world; or you can *recognize* that somebody has not just gone off the deep end and is doing crazy things, but that they're bipolar; or that somebody is frontal – has a frontal deficit – they can't see the consequences of their action more than, say, twenty minutes into the future, and so they behave recklessly.

If you can see into the human mind and see what's going on then you're in a better position to act in a benign way toward that person. You can help them get out of trouble; you can help them get an antidepressant so that they can come out of their gloom; you can find new and interesting ways to pour oil upon the troubled waters; you can be a better human; a more caring human. So I'm not frightened by advances in neuronal theory; I think they will make us more humane, they will make us more caring.

C: But the point was one of replacing folk psychology altogether. It seems like you're still using those common-knowledge terms.

PC: Yes, I agree. Replacing it entirely will take a long time. And by 'a long time' I don't think it will happen in one hundred years; I think it will take a *thousand* years before it is systematically replaced. And of course I'm guessing when I say that, because most of the science lies ahead of us. We don't yet know how wrong we are in how we think about the brain. But we're learning that some of the things we thought about the brain are wrong – and there's an analogy here, from history, that I think everyone will appreciate.

Five hundred years ago we didn't know what life was, what a living thing is, what made something a living thing – and correspondingly we didn't have an idea about what it was for a life to be unhealthy. We had some idea; if you smelt bad and you rotted and fell over dead, you weren't healthy!

But our theory of what made people unhealthy ... There were theories that you were possessed by a demon, or that you had too much black bile, or too much phlegm – or any of the four humors of ancient medicine. And as we know of course, this is a *terrible* theory about health and about disease! And the sorts of things we would do based on this theory, our medical practices, were mostly *pitiful*! [laughs] If someone was possessed by a demon, you would try to drive the demon out. And you could drive a demon out in two ways: you could burn the person at the stake – well, that's not too good for the person! Or another way was you could cover them in excrement! And the demon thought this was a horrible place to be and so would fly away! Of course neither of these things worked, and maybe even medicine was uniformly ineffective.

Now, look how medicine changed our evaluation of what health is, after we came to understand what life is. We came to understand metabolism, and cell metabolism, we understood anatomy, we understood the thermodynamics of life, we understood energy flow; we came to understand that there are viruses and that there are bacteria; we came to understand what life is, including genetic defects in much greater detail than anybody had before – and with it we had a much better understanding of what the difference is between being healthy and being unhealthy.

And the difference allows us to be much more humane. We can cure people. If they have a septic infection we can give them antibiotics; we can prevent disease by giving children an inoculation against smallpox, and do all sorts of things we couldn't do before.

Okay, so that's a happy state. Let me bring you now to the case of cognition – that's the parallel to life. We don't understand very well what cognition is. The virtue of cognition is rationality: being reasonable, being moral. And we have some idea of what being rational is, what being moral is, or what being stupid and what being cruel is, but imagine how much better we will understand the virtues of cognition, when we finally understand what cognition *really* is! I think we will have a much deeper insight into mental health – cognitive health, intelligence, reasonableness, rationality – even things like scientific insight and moral insight.

So I'm not afraid of this at all, I think that it's going to set us free – it already is! We can be better now at treating certain standard kinds of mental illness than we ever could before. But we are still a long way from being perfect and, as I said, it will take a thousand years before we know everything … And probably – I take that back – we will *never* know everything! But as the centuries go by we know more and more. And I think, when we do learn more it changes the way we conceive of the world. And I don't see why our case is immune from the changes we've seen elsewhere.

We think of the heavens utterly *differently* than we did two thousand years ago – a thousand years from now, we might think of cognition utterly *differently* from how we do now. And we will simply throw away the old ways of talking and the old ways of thinking: they will survive in the history books, but even in the market and at the dinner table people will interact with one another differently from how they do now.

C: What's your opinion of Dreyfus' view of socially embedded and embodied cognition?[7]

PC: Oh, I think he's right – and it isn't just Dreyfus who's following on from Heidegger, it's other philosophers like Tim Van Gelder, John Haugeland and Andy Clarke. I think they're entirely right. And what they're discovering is something that I've discovered only belatedly – and that's how important the surrounding culture is to the kind of cognitive activity that any person engages in.

It's important because the conceptual framework you and I use wasn't generated just by us, scrambling around in the forest by ourselves. We downloaded a conceptual framework that had already been tested and tested, many times, by many prior generations. It's called the language that we speak. Languages evolved over time and books that contain wisdom evolve over time and the institutions – the police department and the hospitals and the Mayoral office and the legislature for the states and the Congress legislature, all these levels of cultural control, I'm thinking of the judiciary as well and the way the courts function –

---

[7] See H. Dreyfus & S. Dreyfus, *Mind Over Machine* (NY: Free Press, 1986), H. Dreyfus *What Computers Can't Do: A Critique of Artificial Reason* (NY: Harper & Row, 1972) and H. Dreyfus, *What Computers Still Can't Do: A Critique of Artificial Intelligence* (Camb., Mass.: MIT Press, 1979).

all of these regulate our lives in ways that we're not always aware of. At bottom all this happens, I think, because humans invented language fifty thousand years ago – or a hundred thousand years ago, nobody knows. But it had the effect of making cognition communal, instead of individual. It also had the effect that the language we learn to speak could begin to accumulate wisdom over the years and the decades. And so the language we speak long outlives any person who is fleetingly born, speaks the language, perhaps modifies it a little bit, and then dies. That has allowed for cultural evolution. And once you can speak a language you can write it down, you can write books and legends and stories; use it to make laws to govern commerce, and to govern social behavior – it makes modern human civilization possible. So, I think language is very, very, very, *very* important; it's probably the single most important thing that ever happened to the human race. But I don't think language reflects the basic structure of animal cognition. We are animals in the end, and speaking a language is a trick the brain learnt along the way – a very very good trick. But it used different resources in order to learn that trick – and the other species didn't learn that trick. (Well, I'm not sure … maybe the dolphins, maybe the whales ... maybe even birds, I often wonder what they're chattering to each other about. Is that a kind of language? For all I know it is.)

C: I'm also thinking about art, and other ways of representation and communication. How important are non-propositional ways of communicating, learning, teaching?

PC: I think they're very important. And it's interesting that pictures start appearing on cave walls round about the time that we guess that language began as well. Humans were concerned to represent things that were not present. They could do it in language, they could do it in pictures, so I suspect that those two things evolved alongside each other. There are also other representational media. Music might be a way to represent emotions or a way of representing communal activities like dancing, or chanting.

Yes, I think that those things are enormously important. And when you look at society you realize that language is not the only medium of representation. Think of the enormous importance of blueprints, of diagrams for constructing skyscrapers, diagrams for constructing a coffee-maker, diagrams for constructing an automobile, diagrams for constructing an integrated circuit, drafting and architectural drawing – these things are of incredible importance.

C: A second set of questions concern the problem of qualia. Nagel has argued against excluding the phenomenal features of experience from an account of mental phenomena and thinks that these phenomenological features – qualia, or subjective experience – are excluded from materialist reduction.

PC: He thinks they're special, and physical science will never explain them; that's right. But I think he's wrong! Just straightforward wrong! I agree with him that it is *hard* to imagine how a physical theory of the brain, neurons firing and chemicals sloshing around, could explain something like the visual sensation of red or the smell of a rose the taste of garlic, or something like that. The qualitative features of experience that are present to consciousness do indeed seem to be very very different from a complex neural activity in the brain. Of course it *seems* to be something very different. I grant him that entirely. And when you first come across the problem and someone asks how you're gonna explain this in terms of that, it *isn't* obvious – it's *far* from obvious! But I am unimpressed by this – he is *very* impressed by it. I'm unimpressed and here's why: think of the wonderful phenomenon that was light. And even primitive people thought light was what God created first: [deepens voice; gestures] 'Let there be light!' And there was light. In vain, then, would we try to explain light in terms of things that God only created afterwards. Light also seems special and utterly mysterious – especially to people before 1850, or thereabouts. There were theories that light was particles or light was waves, and philosophers like Wolfgang Von Goethe and William Blake, the English poet, thought that this was just a ridiculous idea. This couldn't *possibly* explain it!

And things only got worse when somebody suggested that light might be electromagnetic waves. An electromagnetic wave is an oscillating magnetic and electric field, at right angles to one another, moving through the ether at a very great speed. And someone might say: 'Look, I know what a magnetic field is – that's what makes compass needles wobble; and I know what an electric field is, that's what happens when you rub your comb and then you pick up little pieces of paper; But what's that got to do with *light*!? Isn't there an explanatory gap there? How can you possibly explain the wondrous features of what light is, in terms of this arcane physicalist, made-up phenomenon, electromagnetic waves?'

And yet as we all know, when you look at all the properties of electromagnetism – how fast it goes, how it's reflected by mirrors, how it's refracted when it goes through a lens, how it carries energy, how it's generated in incandescent objects – it turns out it has all of the behavioural features of light and more besides. Because the theory entailed that there should be such a thing as invisible light; ultraviolet light at wavelengths shorter than blue, and infrared light, wavelengths much longer than red. And people's initial reaction was – 'invisible light?! That's a contradiction in terms! [laughs] Light is essentially visible, and makes everything else visible!'

C: I know what you're going to say next – black yellow...![8]

PC: That's right ... ! Well, actually, I wasn't gonna go there. But here's where, in the history of science, there's a parallel case, I would suggest. And people did resist the idea that light was electromagnetic waves – they thought the idea patently absurd. It took people a long time to get used to the idea that it might be true – and there wasn't any slam dunk [slams the desk] proof at any point, that they were identical. It's just that the explanatory successes of the theory of electromagnetism got bigger, and better, and wider, and after a while, the resistance just sort of – died.

---

[8] See Paul Churchland, 'Chimerical Colors: Some Novel Predictions from Cognitive Neuroscience', in Brook and Akins (eds.), *Cognition and the Brain* (Camb.: Cambridge University Press, 2005).

This is starting to happen, I suggest, in the case of neuroscience and subjective qualia. And if we had time I would tell you again the story I've already told you about the chimerical colours. These are impossible colours analogous to invisible light, but they turn out to be there. But I agree this is just a little case. Neuroscience has a long way to go before it can equal the success of electromagnetic theory. And so the question is still, strictly speaking, open. Still, it's *possible* that subjective qualia are a reflection of a non-physical, spiritual domain. That possibility has not yet been definitively ruled out, but I would bet money on the other side, because I see the science developing and in some cases it's already offered us some explanations – about colour, for example. There is an important area of qualia, where we have systematic explanations from the Hurvich-Jameson neural networks story. Other cases, we're still waiting and hoping. But I don't see the argument that Nagel gives or that Chalmers gives or that Alex Levine gives are – it used to seem that they were decisive – qualia *couldn't be* states of the brain. But it used to seem decisive also, that light *couldn't* [thumps on desk] be electromagnetic waves – and, I'm sorry … it turns out that it could be and it *was*!

C: Would the appropriate answer perhaps be that the kind of reduction that Nagel hopes to obtain is not even obtained in natural science? He would like to have some sort of complete description of contextualized objects, but that subjective character of natural phenomena is not and doesn't *have to be* captured by natural science. It seems that natural science does a lot *without* capturing that.

PC: I disagree. My position is more optimistic than that. I think we *can* explain that qualitative feature – why it has the qualitative dimensions that it does. We can even predict it has new ones, and that's what we are doing – with colour for example.

If you remember, the scientist Munsell looked at the phenomenology of human colour and he saw that all possible colours – at least the ones that humans can perceive – could be located within this double cone spindle, with white at the top and black at the bottom, with all of the hues on the equator, and they would fade through pastels up to white at the top and black at the bottom and gray at the middle. This is a way of describing the range of possible subjective sensory qualia. And, one can then ask: Why do our subjective qualia organize themselves that way? Why is orange between red and yellow? Why is green between yellow and blue? Why is gray between white and black? And the new neuronal theory of color processing in the brain – this is a theory that has been established for at least twenty years, the Hurvich-Jameson theory[9] – now explains, quite adequately, why that space has the shape that it does, why the various colors that are located within it are located where they are. It gives you a systematic explanation – this was supposed to be impossible – of why the qualia are as they are, why they have the similarity relations, the dissimilarity relations, that they do.

This is real scientific explanation, by real physical stuff, of phenomenal qualia. And moreover it predicts some new things. Some things that commonsense didn't know about. And you go and you check these predictions to see whether they're true; the predictions come out …

---

[9] See L.M. Hurvich & D. Jameson, 'An Opponent-Process Theory of Color Vision', *Psychol. Rev.* 64, 1957: 384-404.

So, this is a happy case, not of finding some excuse for failing to explain a qualia, but of succeeding and explaining the qualia surprisingly well, thank you very much. I agree we haven't done it for the whole range of qualia – that will take many many years, but I'm no longer filled with despair. *They* are. But I think they're just arguing from ignorance. They are taking the limits of their imagination to be the limits of what's possible.

C: What do you think are the reasons why traditional artificial intelligence failed, and what are the prospects for artificial intelligence research today?

PC: I think it failed not because the computers that we built weren't fast enough – [hushed] the computers we built were much faster than you or I – I think it failed because the way in which classical AI tried to represent information in a computer was by way of sentences – Propositions! They were sentences in a computer language rather than in English, but they were sentence-like representations. And the computer processed the information by drawing inference-like relations between them. If you like, it was an attempt to push folk psychology onto computers. And we deliberately made these machines so that they would function as folk psychology suggests the way we live – we fill with propositional attitudes the things that the computer knows. It knows that *p*, that *q*, that *r*, and so forth, and then you can let it figure out whether *t* by examining whether or not there was an inferential chain between the premises and the conclusion. Initially things worked pretty well, partly because the computers were so fast – they could do an awful lot of things very very quickly.

But it began to emerge that when you ask them to do things that humans and animals do very easily – like recognizing a face, within a third of a second, or recognizing somebody's voice as the voice of your wife or the voice of your child, or detecting the emotion in somebody's cry – is it a scream of delight, or a scream of terror? – that sort of thing is something humans and animals are very good at – and when people tried to write programs to do that, it isn't that they failed utterly. It's just that it turned out that the programs had to be *enormously* complex if they were to succeed at all. And it took the computers ten times, a hundred times as long as it took humans to do it, even though computers function a million times faster than we do – because they're conducting electricity through wires rather than conducting action potential trains down an axon. Those things ride at about the speed of a human bicycle, this is practically the speed of light. So people began to scratch their heads, thinking 'what's going on here?' And the suggestion – and here I get to the positive side – I think that's why they failed: they misrepresented what cognition is at bottom.

Other researchers started to say: 'well, let's try and take our instructions from the brain, here – how is the brain wired up?' And you have about a hundred million neurons on each retina, and they project their axons back to ten million neurons at the LGN,[10] and they project their axons to five hundred million neurons and you realize that biological brains are doing an enormous number of little computations, simple things: [hushed] … all at the same time – *all* of these synaptic connections attached to *all* of these neurons *all* doing a little something, a very *little* something, *at the same time*.

The contrast with these machines is that they're doing a little computation too – but they're doing it – *phrrrrrrrr* – as an enormously fast sequence. It's easier to do large numbers in parallel than it is to do them serially, or one after the other. So when people looked at the computing power of the brain, given the vast number of cells, and neurons in the brain, and the vast number of connections, it turned out that the human brain was doing more computations per second than the biggest and most powerful computer in the world. The computers were getting close, but again, they're using serial processing, so they're still behind us. So I think that the prospects for artificial intelligence are still very very good. Because I too am inclined strongly toward physicalism, given the success of the physical sciences, but I think success will come when we try to build an artificial intelligence that mimics the way the brain is wired up; then we will start to get interesting artificial intelligence.

C: So, what is connectionism?

---

[10] Lateral geniculate nucleus: the part of the thalamus that receives visual signals from the ganglion cells of the optical nerve, and transmits processed information to the primary visual cortex.

PC: Connectionism is the view that AI should follow the lead of the brain. We should reverse engineer. We should find out how mice do it, and how cats do it, and how human brains do it, and how lobster minds do it, and how ant brains do it. And then try and do it the way they do it.

That leads to an interesting possibility by the way, which worries me a little bit. If we do build a brain, say just like yours Sophia, neuron for neuron, synaptic connections – so we produce an electronic creature, that not only thinks like you do, but has the same knowledge you do, the same emotional profile has been built, we will produce an artificial Sophia. But this Sophia will think a million times faster than the real Sophia, she would think in ten seconds, what would take you ten years.

C: [Laughs] Can you build her please?

PC: I would be afraid of a creature like that, because she would be able to think faster than any of us. Here is a case where our children may be made of metal, but we may love them as much as if they were made of flesh and blood – that is a worry I have. Artificial intelligence is possible, and if we reengineer the human brain to produce an electronic version, a parallel system that is a normal brain, it will function very much faster than normal brains do, and I would frankly be afraid of such a thing. I think we have to tiptoe very carefully here, even though I'm very optimistic about the prospects.

Now I don't think this will happen very quickly, again I think we're talking about two hundred years at least, into the future. But it's a possibility that I think we have to be aware of.

C:But we have created atomic bombs, things that are much more powerful than we are.

PC: More knowledge breeds more power. And power can always be abused, and what the human race has to do at every stage, is to grow up. When we learned to make fire! Uh! That was a dangerous advance! Suddenly you could burn a whole village, here, in half an hour. Did we give up fire? No – we just learnt to be responsible with its use. And when we made atomic bombs, it was terrifying, we could destroy an entire modern city in three seconds. But of course, I think within a hundred years most of our power will be coming from nuclear power stations – we're going back to nuclear power because oil and coal and gas have too many drawbacks. This is another case of technological advance yielding power when we must be careful that it's not abused.

C: How do you conceive of the relationship between science and the philosophy of science? You have said that you think that a philosopher of science doing epistemology is like a cognitive scientist, and so in that sense you think of yourself as a cognitive scientist. But what is at stake in the divisions philosophy of neuroscience/philosophy of science, and philosophy of science/science in general? And what is the difference between philosophy of neuroscience and of the life sciences in general, and the philosophy of, say, physics? Because it seems that the vocabulary and the artillery of neuroscience and the life sciences in general deal with things much closer to our hearts than maybe physics does. And in that sense, perhaps they are also more dangerous.

PC: I think ultimately that all of us – the philosophers and the scientists – are all doing the same thing. We're trying to understand the universe. And we're trying to understand different parts of it. And people used to think, back in the early twentieth century, and particularly in places like Oxford, that philosophy was something very different from the sciences. Sciences were doing empirical research, philosophy was doing conceptual research, or conceptual analysis, or something like that. I think *that's* a made-up story! I think philosophers are trying to explore the conceptual frontiers – but so do scientists, when they make up new theories. Philosophers are distinguished only because … [sighs] what we call a philosophical problem is a problem that's so far from scientific solution that no self-respecting scientist will touch it! And so they throw it over to philosophy and say, here, *you* worry about it! And a successful philosopher is someone who manages to bring some order or insight inside the area, sufficient order that you can then start asking empirical questions – you can start proposing experiments, and saying: 'Oh! I was wrong! You've got to modify that theory'.

It used to be, of course, that it was philosophers who did physics. The department of physics at Cambridge – that department goes back to 1200, or something like that

– is still called the Department of Natural Philosophy – philosophy of the natural world! And philosophy used to encompass astronomy, but astronomy went off on its own, back in classical Grecian times, and physics went off on its own during the Renaissance, and chemistry, which also used to be part of philosophy – remember the alchemical search for the philosopher's stone that would allow you to turn base metals into gold? They thought of that as a department of philosophy. As disciplines become more self-contained and more driven by empirical data, we don't call them philosophy any more, we call them sciences. Now, there are always some residual problems left, like the mind-body problem, or the problem of life – there's a problem that solved itself in the middle of the last century. Biology went off – it too used to be part of philosophy, just like chemistry was. All of those cases are cases of philosophical success. We finally get enough of a grip on a problem that you can start performing experiments, to test the theory and to modify it. We finally learn from experience rather than sheer speculation, mere stabbing in the dark. Philosophers are trying to do the same things that scientists are. They're just addressing some of the hardest questions, and they're engaged in stabs in the dark, and so, philosophy moves forward more slowly than the sciences do. Now, you said you had a worry. What was your worry?

C: I was thinking of cases where the language of science has been used to promote political goals. For example the use of holistic biological language by the Nazis to promote their totalitarian goals: the idea of the *Führer* as the head and the *Volk* as the body of an organism that functions in unison. Those kinds of metaphors that travel from a domain like biology – especially from life-science domains, whose vocabulary seems compelling – to the domain of politics. To what extent should philosophical work be constructive – what balance needs to be struck with a negative, critical theory?

PC: Well, yes, evil metaphors are certainly just as possible as benign metaphors. The metaphor of a master race, ruling over subjugated races, was a lousy metaphor and it was a misuse of biology. The idea that evolution was something that leads from lower to higher and that northern Europeans were the most evolved was a false conception of how evolution works. Evolution works in a radiated fashion rather than arrowing towards some goal.

I think the broad answer is that science can provide compelling metaphors for a number of things. And sometimes they are very revealing. Newton said that the moon is just like a flung stone, it moves in an elliptical arc focused on the earth – that's an illuminating scientific metaphor. And then there are other metaphors that aren't so illuminating at all, like the notion of a master race, or the notion of evolution focused on the *Führer* itself, or on blond-haired Aryans.

We have to resist the ugly metaphors. Science is as rich a source of metaphors as anything else, and we have to resist the bad ones and nurture the good ones and we have to learn how to tell the difference. And that means that we have to *test* them in systematic ways – they have to be subject to criticism. The Nazis weren't interested in having their metaphors tested in systematic ways, they were interested in using them for political purposes. Newton was interested in having his metaphor tested, and he was lucky and most of the tests turned out very well indeed thank you. So in that way we can discriminate between good metaphors and bad metaphors. Beforehand you often can't tell the difference. You have to get them in a position where you can test them.

Some of them of course will look morally ugly, even before you can test them. Maybe then you want to resist them. But I remind you of cases like the smallpox vaccine. When it was first invented, in the early 1800s, the Church thought it was a *horrible* thing, because they thought that if you were giving people vaccinations you were playing God. Whether or not you got smallpox and died was God's will, and if you were protecting your children by giving them smallpox vaccine, you were intervening in God's plans, and the Church tried to prohibit the smallpox vaccine for quite some time. But after fifteen years someone did a survey in Northern France, and the number of deaths of innocent children from smallpox fell from one hundred and forty-five thousand to four thousand in just fifteen years. Now, all of a sudden it starts to seem like: no, smallpox was not a case of being morally evil, it wasn't a case of playing God, it was a case of protecting innocent children from something that has nothing to do with them.

Now, it's never easy to see what's true and false, it's never easy to see in the long run what's right and what's wrong. One needs to keep an open mind and evaluate things as you go along.

C: Is connectionism a good source for metaphors?

PC: I think so. I think so, yes. But the research is in such an early stage, it's still at a very theoretical stage, so I can't claim any grand successes. It is a fertile metaphor because it suggests that the way, say, the visual cortex represents the world, could be more like the way your television screen represents a baseball game. If you go up at the screen and look really closely you see all those little pixels: there's two hundred thousand little pixels – some of them green, some of them red, some of them blue – and any little picture – say Dan Rather, reading the news – is a particular pattern of activation levels across all of those pixels; some of them bright, some of them dark. Well, any particular representation across the visual cortex in the brain is a particular pattern of excitation levels across one hundred million neurons – not two hundred thousand, but one hundred million! So, the resolution, if you like, of the visual cortex, is much higher than a television screen. And that's true of a monkey, that's true of a mouse – this gives you a new respect for the representational power of the brain. It may be representing – not always like a two-dimensional picture – but representing with activation levels across millions and millions of neurons. And then it transforms one representation into another – because you've got many different populations in the brain. And you can do computations over these representations.

And this is a metaphor for conceiving what's going on inside the human brain. It looks like a useful metaphor for understanding motor control, facial recognition, auditory recognition; it looks like a very promising metaphor for human research. And that's why we're pursuing it. But the proof of the pudding is in the eating. We'll see how this research programme pans out. It could very well die, just as classical AI died. After ten or fifteen years of trying, this may wither on the vine as well.

C: I guess part of keeping the metaphor tight relies on reproducing the architectural structure of the brain adequately in your model – figuring out the criterion of what's an adequate simplifying assumption, and what's just plain misrepresentation.

PC: Well, that comes out in the testing. If you can get useful idealizations, then fine. But if you end up misrepresenting what's there and the explanatory power gets feebler and feebler and the metaphor gets more and more and more strained … That's what happened with classical AI. The idea of an internal set of sentences crunching away according to logical rules – that turned out to be a poorer and poorer metaphor. We strained it and strained it and the behavior of the machines that were being programmed, the investment didn't justify the payoff. And that's why people are switching to new ways of trying to create AI, because the old ways failed. Well, these new ones may fail too! But at the moment they seem to be flourishing! So keep your fingers crossed – and come back in ten years.

C: This seems very classical-Greek: the idea of the philosopher doing the work before the scientist steps in.

PC: Yes it is very much like the classical Greeks. Aristotle was a proto-scientist, and Plato was a proto-scientist – but he was not very good [laughs]. And then if you look at Theophrastus and Strato of Alexandria who came after Aristotle at the Lyceum … Were they philosophers, were they scientists? It's a silly question! They were *both*!

C: My only worry is keeping a critical distance from the practice of science, insofar as that enables you to see the mistakes, see the confusion. So I guess both philosophy and science need to be there. And keeping the balance is the tricky thing.

PC: Yes, keeping the balance is the tricky thing. You can't have a balance until you have *both*.

Nevertheless Empire

Clémentine Duzer & Laura Gozlan

Pestilent fumes had tainted the atmosphere of the suburbs so that little by little passers-by began to steer clear. But some remained, unafraid, while the epidemic continued to spread. Such was the case with private investigator K9: his thoughts were haunted by a woman of the worst kind.

She ran a brothel.

*

'He used to run an out-of-town osteopathic clinic, took on a few drugged patients for three large ones a week.

As you know, the epidemic was swiftly killing off the hired help. Our workers were spilling all over the lino, you understand, liquified bones softening the flesh.

It was all going from bad to worse. We were hiring younger and younger recruits, but it was no good.

We were about to shut up shop, before we had the idea: the graft.

We had some failures. Yes. Automutilation with fan blades. In short, it turned against itself.

So we eventually discovered that female parts are much more co-operative than male. Accordingly, as you will understand, the very best grafts come from domesticated animals ... '

Islamic Exotericism: Apocalypse in the Wake of Refractory Impossibility

Reza Negarestani

Unlike other strains of monotheism, Islam cannot be said to include the idea of an apocalypse in the sense in which we usually understand this word. In fact, the radically external, 'impossible' (non potest) *nature of Allah renders the judaeo-christian apocalypse structurally impossible* (impugnable). *At the same time, Islam posits an apocalypse that is neither feared, hoped for or expected, but which, in the ideal of pure submission, is inhabited by the faithful as pure impossibility. In order to comprehend what appears, in its violent irruption into western chronology, as the apocalypticism of radicalized Islam, we must understand how Allah's absolute externality has as its consequence a different conception of temporality, different mechanisms for the maintaining of faith, and an apocalypse which cannot be reduced to a chronological moment or a possibility in unification.*

The Outside of Outsiders. The Islamic account of Genesis spirals around a non-ontological unity. Firstly, as Mollasadra (1571-1640), the Iranian philosopher, emphasizes,[1] Allah is not 'Being' (yet neither is it *nihil*); its truth can never be known, either through being or through non-being, either before or after the Apocalypse. Secondly (and in parallel with the foregoing), Man can never attain an integral unity with God – such a unity as would, in other strains of monotheism, exalt and transform Man from his former (*quondam*) state. Man can only return to Allah, not unite with him. Unity or completeness in terms of the human is only entailed by affordance,[2] a state of mutual affordability or an economical openness: the state of being open to. In Islam, however, God is constantly external to Man, and only 'unlives' through the impossible, an absolute *potestas* so ultimate that it is im-*posse*-ible for Man; Al Farabi (870-950CE) in his *chef-d'oeuvre*, *On the Principles of the Views of the Inhabitants of the Excellent State*,[3] clearly brings into conjunction the possibility of possess-ability and impossibility, to suggest an *im-possess-ability*.

[2] Polish philosopher Roman Ingarden, in his works focused on ontology – written after breaking from Husserl's phenomenology through a critique of transcendental idealism – expounds on the problem of openness and affordance, suggesting that closure (or modulated/economical openness) is a priority for open systems, and analysing niches as power projection zones and inhibitors of unwanted interactions and communications. The openness of the niche protects itself from what makes it open, by opening itself to what makes it closed. Only through such an openness can the existential moments be afforded, and modes of Being are then able to emerge. For more details on affordance, see my 'Militarization of Peace' in Mackay (ed.) *Collapse* Vol. I, 72n.11.

[3] Mollasadra (Sadr al-Din al-Shirazi), *The Beginning & the End on Transcendental Philosophy (Al-Mabda wa'l- Ma'ad fi'l-Hikmat al-Muta'aliyyah)*, Vol. 2 (Tehran: Sadra Islamic Philosophy Research Institute, 2002).

Possibility must be afforded if it is to be reached, its *potenz* must be attained, possessed and sometimes even activated through a dynamic course of action in order for it to be released (X is possible for Y if and only if Y affords X *i.e.* if Y is able to reach X and authenticate its possibility; or, Y must attain the capacity to afford X as a possessable objective). But Farabi bifurcates impossibility into a 'Latent/Passive Impossibility' (an impossibility characterized by its quiescence) and an 'Active/Unfailing Impossibility', where the former is merely a symptom of a subjective capacity or temporary lack of mutual affordance. That is to say that Latent or Passive Impossibility describes a situation where, once Y achieves the desiderata necessary to capacitate itself and afford X, the Latent Impossibility will be actuated as Possibility. Latent impossibility attests to the fact that the impossible object(-ive) (X) still remains in the horizon (boundary) of the subject in relation to which we attribute its impossibility; it is necessary only that it be afforded and that it mutually afford the subject in order for it to become possible (possess-able). At the same time this makes it certain that the latently impossible object(-ive) remains bound to the logic of the boundary, of conditions and characteristics (having its own idiosyncrasies which must be afforded in order to be activated and become achievable for the subject Y). Thus it remains existentially perusable and intrinsically inert and transient (it is not permanently and fully impossible). And it is neither functionally nor spatially external to the subject Y; on the contrary, it (latent impossibility: X) exists just as the subject Y exists, waiting to afford X to turn it into a possible (possess-able).

Christian luminary Nicholas of Cusa (1401-1464AD) argues in *De Possest* (a neologism best understood by breaking it down to its pre-existing elements *posse est*) that 'God alone is what (He) is able to be.'[4] Nicolaus Cusanus expounds on a microcosmic proto-monadic system which is shaped around his term *Possest* (*Posse Est* or *Können-Ist*) which draws an intrinsic and interiorized line of alliance between Able-ness (being able to) or Actuation, and *Potentia* or Possibility. To exist is to be possible in the sense of *possest*; or more accurately, 'able-ness' and 'actuation' are immanent to potency and possibility. Possibility alone renders existence, just as potency alone renders able-ness. According to Cusanus, *possest* means that 'possibility itself exists' ('*posse est*'); then he concludes that because what exists, exists actually (existence is the actuation of possibility), the 'possibility to be' or the 'potentiality to be able' exists insofar as the 'possibility to be' is actual. Cusanus calls this *possest*. In other words, and from a different etymological and biblical perspective of the term *possest*, it means that the 'potentiality to be' exists as effectuation and able-ness (*posse/possibilis*).

The proposition 'God is *possest* (actualized-possibility and able-potency)' captures an omnipotent quality, to be opposed to created beings who can never completely fulfill their potentialities and can never fully reach their possibilities. This intrinsic and autonomous transition in *possest* between possibility and actualization, or potentiality and able-ness, can only be established in the presence of capacity or affordability; because actualization or able-ness emerges when possibility or potentiality achieves and satisfies a certain capacity (*i.e.* in the case of chemical processes, reaching a certain gradient in potency to trigger a specific action) that leads to a certain actuation and effectuation. Designated actuation is the matter of designated affordability, or the range of capacity for a potency which must be fulfilled (afforded).

---

[4] See Nicholas of Cusa, *Metaphysical Speculations*, Volume 2, trans. Jasper Hopkins (Minneapolis: The Arthur J. Banning Press, 2000), *A Concise Introduction to the Philosophy of Nicholas of Cusa*, trans. Jasper Hopkins (Minneapolis: The Arthur J. Banning Press, 1986), and *Nicholas of Cusa: Selected Spiritual Writings*, trans. H. Lawrence Bond (New Jersey: Paulist Press, 1997).

The necessity of capacity as the ground on which possibility and actuality are mapped together, or in other words, capacity as what connects possibility and actualization together, can now be examined through an apagogical argument (*reductio ad impossibile*) and in conjunction with the theological context at stake here. To this purpose, we shall assume that the connection between possibility and actualization (or potentiality and able-ness) is direct and immediate, and they operate in regard to each other without an intermediary, a *capacitas* which can contain something.

In the absence of capacity and affordability as bases which underlie both possibility and actualization, every possibility could lead to any actualization and any able-ness could be ensued by a potentiality with no required gradient or degree of quality or quantity. Or in other words, no particular ability would exist, since it is the capacity and gradient of fulfillment that lead a certain potentiality towards its able-ness. Once we assume that capacity and its subsequent affordability do not exist in the transition of possibility to actualization – ergo the *possest* of God – there would not be any boundary (limit) or compass for the actualization of a possibility, or *vice versa*.

Consequently, in the absence of capacity, the possibility of being God and actualization of that possibility – being the Divine, that is – for Man would be equal to the *possest* of God itself: so to speak, Man and God would be potentially and actually at the same level; a theological conclusion that is not only invalid for monotheism but also confutes its own grounding structure. Therefore, to this extent, the relationship between possibility and actualization, both in the actualized-possibility of God (*possest*) and possibilities of Man, is subjected to the economy of capacity and ability – in the sense of tolerance (range of modulation) – which is an economy of affordability rather than openness, environmental surround rather than radical outside. Now if capacity is latently and potentially attainable at all times (can be afforded at any time) and it constitutes the grounding nexus of possibility and actualization for both God and Man, then Man can afford the Divine all the time – which is not the same thing as 'Man being God' or 'becoming the Divine instantaneously'. God can be afforded all along. This affording of God – which is delineated as the possibility of Man being actualized as God (ultimate actualized-possibility or *possest*) and is not 'to be God itself' – incessantly maintains the position of the Divine within the range (*confinium*) of Man's affordability (either incapaciousness or capaciousness: capacity), or in other words, interior and endemic to Man's *ecologia* and existence.

Following Cusanus, in God's *possest*, actuality and possibility can correspond and conform to each other symmetrically (with an equal scale) only if the capacity between them is equal to the unit distance or the unit capacity. That is to say, *ab* is posed as the unit measure (*unus*: 1) for any other variation in actuality, possibility and capacity *i.e.* a unit in the threefold of existence. Accordingly, *possest* can be diagrammed as *ab,* which is equal to the unit capacity and the symmetric fold between actuality and possibility (see Diagram 1). To put it differently, *possest* as the complete symmetry and corresponding state of possibility and actuality (God) can only come to existence if both actuality and possibility are aligned with the Absolute or the un-conditioned (x=0); since any condition, or more concretely, any variable step (*gradum*) or status, either in possibility or actuality, is formulated as a deviation (*d*) from the unit distance or the unit capacity ($d \succ 1$). To this point, beings are perpetuated as variations, and their existences are deviations from the unit capacity (*ab*), which is immutable to variation and digression. For created beings, either actuality or possibility is characterized as the ratio of this deviation to its corresponding capacity. For instance in Diagram 1, for possibility of a created being this ratio of deviation is b_1b, *i.e.* b_1 to b_1o (similar to a cosine function: b_1/b_1o). Likewise, the existence of a created being becomes tangential to the existence of God. The existence of a created being is posited as the ratio deviation of both its actualities and possibilities (a_1, b_1) to the unit capacity (*ab*) which is *possest*

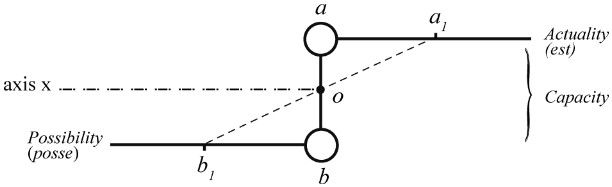

Diagram 1. The Threefold of Existence

or God itself (similar to the tangent function): $(a_1 b_1)/(ab)$.

Here the qualitative or quantitative characteristics of One and its formation as a specific *com-plexus* (or according to Cusanus, God's *complicatio*/enveloped in relation to the world's *explicatio*/developed), namely unity, should not be presented as the reductive 'indifference of the unity itself toward itself' (Hegel) by way of totalization or exclusion. Unity here serves monotheistic theology only by the virtue of its (i) positioning, (ii) the alignment it takes and (iii) the fold it plaits (as a fold-line which is itself a plait) in the threefold of existence. It is by way of these three acquired attributes (subsidiary to its unitary quality) that unity – as of God – more than being the exclusive oneness, is posited as the unit capacity, the measure (*metron*) of affordance. And affordance is the only and exclusive destination for the openness between Man and God in this territory and the ontological relevancy between possibility and actuality. Only through economical (dyslogistically economical, of course) possibilities of affordance or reciprocal affordability, can actuality be posed as the ideal realization of possibility, an end in itself, an entelechy. Unity of and through God is the fold of connection and communication made in the name of affordability and capacity (so long as one can afford). Neither unity nor its formative processes (unification) are totality or exclusion in themselves. To highlight the problematic of 'Unity as immanent totality', it can be suggested that different numeric principles can be applied to unity itself, in the same way that Kazimierz Twardowski[5] proposes that Leibniz's spiritual system is subject to two different numeric principles. Consequently, Leibniz's system only includes monism of kind but not numeric monism. Unity as a process is perpetuated by two main numeric systems – of which at least one is manifold – which are applied synchronously together from both ends in the process of unification. In Christian theology, one is the numeric multitude or the participation of people (Man) in God; and the other is the numeric monism of God, which also envelopes the monism of kind. Moreover, one can embarrass the presupposed tautology ('I be that I be' [Exodus 3:14]) that is associated with One not only by the logic of exception (which again is directly extracted from oneness as counter-generalization) but also by the singularity function of One by which One separates from its unitary predeterminations. At the same time, from another direction, infinite growing processes can encapsulate the same singularity of One and develop the same 'object conception'[6] that is applied to One. If One consolidates everything under its banner by any means possible, every anomaly, unilateral development, exception, germinal multiplicity and constant driftage – that is to say, infinite perversion ($d \succ 1$) – can also be gathered under the flag of One. This is the remobilization program (in a military sense) that is harvested from the double-dealing dynamism of heresy. If God basks in his house, let us reconstruct it according to the laws of demons.

(*unbedingt*) of God makes sense; but only at the cost of postulating the existence of God as capacity, or more accurately, the unit capacity in the threefold of existence. The *possest* of God is transversally interposed between actuality and possibility, an imposition that not only establishes a monopoly of God, for which beings are mere excursions, but also economizes existence. God is the *metron* of affordance; Man's affordability tangentially folds over and contains God (see Diagram 1).

The affordability of God (*i.e.* God being afforded or God within the fold of Man's existence) perpetuates the Divine as domestic or in-the-house (cohabitant) in connection to Man. The Almighty's omnipotence is merely effectuated in the wake of its confinement, which includes and covers Man too; while the latter is a part, the former is only environment, the neighbouring, the one that is tethered to the part's capacity. If the Triune God is existentially possible, it is because this God cohabits the same space in which Man resides, which is functionally bound by the economical closure of affordance between the two (Man and God) and is rendered volumetrically limitless by the opposition between 'the becoming of Man' and 'the Being of God', which determine the ongoing perpetuation of affordance (see Diagram 2). The affordance or mutual affordability between God and Man is an economical openness through which overlap and 'radical communication' (indifferent to capacity) are not attainable. Here, communication and overlap can only take place in the presence of and within a third capacitor, which is situated as an intermediate state (*meso-philic*) by both sides and interposes a buffer between them capable of consociating and bringing the sides to one capacity, coordinating a domain of communication for God and Man. This capacitor is partially shared by both sides and does not preexist for them individually; it is conceived and formed by the movements of Man and God to each other (see Diagram 2). Coexisting contemporaneously and dynamically, these diametric movements whose course of action is affording, participate – in the sense of orchestration – in the coordination of a communal capacity, a *hospitium*. The hospitality of axes, here, cannot be exalted into an act of conjoining, unless through the act of lodging each party on the basis of their regulations, ineptitudes and failures toward each other and in themselves – the hospitality associated with the foundation of lazar-houses or the erection of hostels as loathsome places of dejection and parsimony. If God and Man are incapable of fusing with each other outside of their affordability, and for that reason their oneness is eternalized through a shared vessel (*vehiculum*) which renders both subordinate to each other, they never fully overlap each other; though at the same time they do overlap on a bounding level. In other words, the affordance or mutual affordability between God and Man can only lead to unity (continuity in and of One, *un-us*) when the boundary of Man is afforded (economically affirmed) by God. In the wake of Franz Brentano[7] and later, more concretely, Roderick Chisholm's theories of coincidence, which propose 'if something continuous exists as a boundary, it must be in connection with other boundaries and it must pertain to a continuum of higher dimension',[8] the continuity of God and Man in a 'shared capacity' determines and marks out not only the boundary of Man, but also of God. Unity cartographically outlines the shared and coinciding boundaries of Man and God, the afforded boundary. In unification as culminating affordance, all possibilities – including the possibility of unity and the possibility of Man's deification – are molded by the capacity and boundary of Man which necessitate a boundary for God as the continuity of Man's boundary in unity. The possibility of unity entails the possibility of a coincidence of boundaries in the congenial company of

Man and God.

Having ratiocinated the threefold of possibility, actualization and – *en passant* – meso-philic capacity, the investigation of Possibility and Impossibility for Man and God can be pursued by, and in conjunction with, Farabi's Islamic question of Active/Unfailing Impossibility.

For Farabi, Being and being united with God demarcate a passage that is trodden through the intersection of Latent/Passive Impossibility and Possibility (symbolised as A∩B), and whose boundaries are outlined by the 'symmetric' difference of Latent/Passive Impossibility and Possibility which is the union of both minus their intersection and can be symbolized as (A∪B)–(A∩B). Farabi refutes any manifestation of 'possibility of Being' in the existence of God, because possibility of Being is – with the same scale or *sun-metron* – symmetrically determined by the relative complements of A and B (symbolised as A–B and B–A) which maintain existence by exclusion and debarment of other parts (simultaneously full A and full B) (see Diagram 3).

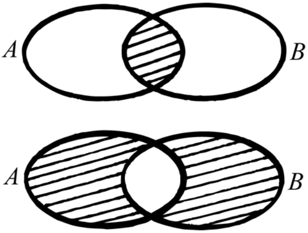

Diagram 3. Union and Symmetry in *Possest*
(After Nicolaus Cusanus' *De Possest*)

The Christian doctrine of Apocalypse and Return to God adheres to the model of Latent/Passive Impossibility; it is maintained that the Unity with God which is now impossible will eventually be afforded, and, as possible, will ensue. Affordance, or 'the openness to possess', is the *causa causans* of 'possibility (*posse*) to be able and actualized'. In the presence of affordance, possibility is assumed as the capacity (amplitude) or the containing possibility to do something. Possibility as affordability – in its economical receptivity and investment – exists prior to possibility as ontological potency. Parallel to, but entirely dissociated from, Latent Impossibility, it is the other impossibility (im-possess-ability) delineated by Farabi that designates the plane on which Allah pervades everything in Islam; it is Active or Unfailing Impossibility, which cannot be afforded under any circumstance. Hence it perpetuates and postulates itself outside of possibility and possess-ability – that is to say, potentiality for Being and being united. Farabi's Active Impossibility, which suggests itself as consistent and radical, equals radical externality. Allah's externality renders it im-possess-able; its active impossibility originates and reinforces its un-existence or im-possess-ability for all modes of existence. But at the same time this un-existence is not that of the *nihil*, since it is immanent to existence and all modes of being. Allah does not afford, but is the total openness which must be afforded, regulated, grounded and moderated in order to be transformed into modes of existence, into survival; otherwise, its active im-possess-ability would be the resolute terminus of all beings.

According to Islam, then, existence is the consequence of the prevailing impossibility of Allah, and Allah's absolute openness can only be afforded (that is, submitted to economical communication or the affordable passage from passive impossibility to possibility) but not radically communicated. Ontological modes of openness or ‘openness bound to existence’ cannot be absolute, since they would thereby transgress their existential necessity (first and foremost, they must survive and their openness is bound to their logic of survival). They merely afford this active impossibility and maintain their survival through its im-possess-ability, since possessing it in its entirety would be the undoing of affordance, and consequently of the survival that affordance makes possible and maintains. Absolute openness cannot be communicated, it can merely be afforded; and existence emerges out of this very lack of radical communication with the Absolute Openness (or in Islam, the impossibility or im-possess-ability of Allah) and its pathological symptom, affordability.

The revelational conclusion or the unitary apotheosis with God is defined as coming to union with God by participation, or participation in God through the Son. In this revelatory process, the aperture of man's epistemological focus in relation to the Divine must surpass his ontological isolation by means of a third capacity outside his own capacitance or the state of his capacity: an *extenta* whose boundary (or boundedness) ontologically shares and overlaps that of Man, and whose epistemic expanse (of unboundedness) intersects with the Divine. The mechanism of ‘coming to Union’ or unificatory disclosure of the Apocalypse (Revelation), while it is subjected to variations of either ontological or epistemological directions, constantly partakes of a fundamental revelatory process in a monadic or unitary sense: participation by the necessity of incompatible entities or parts and their ordained unity, *i.e.* difference, and adding a quality or amount (a content) to the difference to satisfy and fill it. This attributable content which takes form as *contentum* (the conjoiner) and *contentus* (the satisfier) cannot be anything. Precisely speaking, it should be – by the virtue of its satisfying function – determined and individuated by exclusion, or the logic of negativity, to locally fill and neutralize the effect but not the cause of the difference – that is to say, to be 'something specific' at last. This 'specific something' must share the contents of both the Divine and Man without transgressing their capacities or boundaries outlined by affordance, which actuates the coincidence of boundaries (*viz.* necessitating both the existence and coincidence of boundaries) between God and Man; it can be the groundwork of participation and affordance if and only if it is perpetuated by the sum exclusion of both sides – neither outside of X nor outside of Y. To this extent, this certain content reinvents the autonomy of participation in ostracism and repels the ephemerality of its existence by double-satisfaction. The Son is the ultimate *contentus* of Revelation and Unification, the double-satisfier of Platonic participation. If according to Hans Urs von Balthasar, transcendence to Christ manifests the apocalyptic consummation of History and Christ gives the world (the *exteriora* of the created world, the *interiora* of human essence and the *superiora* of heavenly order) its *Gestalt*, then both the configuration and consummation of the world (essence itself) exist only in affordance and economical participation through capacity.

We shall become Sons by participation (methexis)
(Cyril of Alexandria)
Totus Christus, Caput et Corpus

Four factors are involved in neo-Platonic and later Augustinian doctrines of *methexis* (participation): **(i)** The divine source of experience or the horizon (*horismos*: whose formation is characterized by an inner hegemonic boundary – *perata* – and an external boundlessness) of participation, which affects the spiritual senses of the human beings. Apart from this horizon there is no motivation for participation, since *methexis* presupposes the lack of an autonomy between participants, *i.e.* participants undergo *methexis* through their lack of autonomy and the hegemonic autonomy of the Divine. **(ii)** The *telos* of experience or the intention of the source, the purpose and goal for human being, which is unity with the Divine. *Methexis* presupposes myriad levels of being necessarily emanating from the Divine to unify later with the Divine as the ultimate One. **(iii)** The transformation brought about through experience which is based on the capacity/affordability between participants (*participans*) with each other, on the one hand, and the participant with the Whole or the *contentus* of participation (*participatum*), on the other. The persistent interference of capacity and affordance in participation, and in the reciprocal relation between participation and participants, imparts a self-correcting or gravitational quality to the collectivizing process of participation towards a satisfactory collectivity – thereby constraining in its collectivization dynamics – for the participants and the content of participation. This state of participation undertakes the together-ness of relationship as long as the capacity of nexus can be fulfilled; therefore, it operates as 'coming together (*com*) under a bound or an obligation (*munis*)'. This is an Obligation that can only exist as One (*unus*) because it is directed and achieved by and through capacity and affordance between entities in participation, or to be exact, by the collective affordance or the 'shared' capacity, the capacity shared by all as the sum affordability that can be fulfilled by all. For such an obligation, which can only survive and influence as a shared capacity, the plane of movement is necessarily one of convergence and concentration. Here, the participation dynamic inexorably describes a transition from *munis* (collective obligation) to *unus* (being one) in the wake of a collectivity (*com*) which perpetuates itself through affordance (see Diagram 4). This is why, in the New Testament, discussions and references to participation are mostly expressed in terms of *koinonia* (in its Platonic sense) which signifies sharing, and suggests an obsession with economic fixation, rather than *Methexis* (participation). **(iv)** The affective states that accompany the experience of participation are already modulated by the affordance between participants and the Whole, and the hegemonic autonomy of the Divine, which imposes unity with itself upon all modes of participation – *methexis*.

The Christian apotheosis promises a final unity with the God through a transcendental participation or *methexis* (or what Theodore Runyon calls Orthopathy)[9] – with the Son (as an indispensable intermediary or channel-regime of this exchangeability, the double-binding chain of the Atonement, the double-satisfier) and the other sons (men)

Com-: Coming together-ness of parties from both ends

Diagram 4. Monad's Communication Dynamics

taking part in a process of concrescence (the theological becoming grounded upon economic participation or *methexis*) oriented towards unification with God. But Islam openly rejects such a theologically relieving covenant. Man can never be unified with Allah and Allah will never be revealed to Man; the knowledge of Allah can be obtained neither through the affirmative desire of *cataphasis* nor the logic of negativity and emphatic negation of *apophasis*. In more precise terms, in Islam, unity with the Divine is eventuated neither on the ontological nor on the epistemological level. The son can never return to the father since there is no son and no father; there is only Allah, external to all beings and their surrounding outside *i.e.* the possibilities of their transgression. Because transgression is conveyed on the plane of affordance and the dynamics of 'being open to', a tactical line of openness constrained by the plane of logistics rather than the subjective line of command. This radical outsideness, however, is not prompted by the jealous impulsions of God, passed on to the victim(-ized) body of Man (a parasitic creed stubbornly energized and exploited by the exchangeability between *lex talionis* and victimology, their double-binding system carved on to the monopoly of God), but rather that immensity that is the undoing of Man, of all potential sons and the Father alike.

> While God was the exclusive source of the revelation to Muhammad, God himself is not the content of the revelation. Revelation in Islamic theology does not mean God disclosing himself. It is revelation from God, not revelation of God. God is remote. He is inscrutable and utterly inaccessible to human knowledge [...] Even though we are his creatures whose every breath is dependent upon him, it is not in interpersonal relationship with him that we receive guidance from him.[10]

Islamic Apocalypticism is not a contemplating process, a river (a flowing transcendence or a process of concrescence [A.N. Whitehead])[11] tending towards unification with God, as the complete state of its refinement. It is a process which seeks to ultimately and fundamentally

---

[10] Edmund Perry, *The Gospel in Dispute: The Relation of the Christian Faith to other Missionary Religions* (New York: Doubleday, 1958), 155.

[11] *Concrescence* emphasizes an economical participation through the theological doctrine of *Diaconate* which assembles a regulating all together; the itinerary of this process is continuously guaranteed by the responsibility of each entity to serve and survive for the other, becoming a passive negotiator-field to save the continuity of the self-refining flux. In such a participation (*methexis*), one cannot escape and still survive; the entities which cannot bear this dynamic but fully economical participation are automatically forced to leave the dynamic network of pseudo-flux (forced to be dumped out of the dynamic course of the flow).

'surrender' to the impossible which remains external to being (absolute surrender or pure *Islam*). Submission occurs according to the imperceptible Will (*Hoda*) of the im-*posse*-ible (Allah). Everything is preserved and maintained by a pure externality, not because of the power – ontological or epistemological sovereignty – it imposes upon being, but for the sake of externality itself – the radical outsideness that simultaneously provides the possibility of being, affordance and survival. The process of surrendering and submitting (or *Islam*) which leads Man towards God is suddenly disrupted by *Qiyamah* (*Ghiamat*) which is wrongly translated as Apocalypse. *Ghiamat* is a vast desert where Man finds that he can never reach (possess or afford) the Absolute or the Unconditioned (*unbedingt*). Here Man is totally disillusioned (one of the functions of *Ghiamat* is an awakening, in the sense, not of resurrection, but of disillusionment, *entebaah*) of everything he 'believes' himself to possess, and of existence as ontological corollary of affordance. Islamic Apocalypse occurs where (not when) Man grasps the utter externality of God to himself (an externality based on the radical outside-ness of function and an unaffordable openness of communication – rather than on a distance, which in the Islamic account of the divine is regarded as the utter glory and generosity of God to Man). Deleuze and Guattari[12] diagram the Absolute in terms of a movement qualitatively different to relative movements but necessarily associated to them. In Islamic Apocalypse all movements which give rise to the Absolute (and flow 'through' and 'as' Islam) abruptly cease to process (they cannot install Man as multiple or even One); the process of rendering a Unity by exception or subtraction fails before it is initiated. Before such an impossibility, the Deleuzian escapism to the Outside is an aesthetic movement based either on the idealism of reaching/possessing the Impossible (the active im-possess-able) or on becoming open to an absolute openness which can only be economically afforded and explored by the survivalist policy of 'being open to' and its escapist lines. This radical openness is so unrestricted that it turns all modes of openness ('being open to' in particular) and lines of escapism into a romantic struggle to tolerate it. However, every instance of toleration of this immense openness (even in the form of economical openness, escapism or 'being open to') results in a suffering which affordance and all economic regulations carry with themselves as the consequence of their restrictions and survivalist moderations. Economical openness (or escapism, which employs its dynamism on the plane of 'being open to' *i.e.* economical openness) as an instrument for moving towards Absolute Openness, operates in the form of an economic reformation of affordance and suffering. For such an economical openness relies on a movement or escape according to a subjective capacity – bound to the capacity of the Whole – which can crack at anytime, leading to a crisis of survival and toleration at different levels. This crisis or symptomatic side-effect associated with economical openness is both the result of the lack/capacity it must include in order to survive (regulation of communication) and of the radical openness which affordance cannot fully regulate and which, therefore, will eventually cut it (the subject of economical openness) open. Is escapism on the plane of 'being open' therefore a reformation of Atonement, its reinvention in another territory?

---

[12] Gilles Deleuze, Félix Guattari, *A Thousand Plateaus: Capitalism and Schizophrenia,* trans. Brian Massumi (Minneapolis: University of Minnesota Press, 1987), 509.

Escapism presupposes that openness all happens on the plane of 'being open to' (it excludes the radical side of openness or openness from the Outside *i.e.* 'being opened by'). The propulsive body of 'the line of flight' (Deleuze and Guattari) runs on this plane of openness to explore the Outside, or in other words, to be open to the Outside. Consequently escapism is involuntarily prone to unlimited appropriating functions and restrictions of capacity, since these maintain the openness for both the subject that escapes and the environment that affords and supports this escape – the capacity or affordance of the Whole. As the escape reaches critical levels in opposing the gravitational forces (territory, the State, organic life, *etc.*), its capacity for 'being open to' becomes a burden of tolerance and confinement (the limits of capacity) rather than a propulsive engine. To this extent, the over-tolerance for escaping becomes equal to suffering (*thlipsis megale*) for salvation. When it comes to the exigency of capacity, a scintilla of openness on the plane of 'being open to' – which is always oriented in opposition to the function of gravity but is aligned with affordance – can be likened to a tribulation whose conclusion (salvation) is not liberation from capacity but arriving at, shifting to, a reformed capacity.

In Islam, Man does not reach the Absolute, nor does the Apocalypse manifest the Absolute. Unlike other apocalyptic revelations, Islamic Apocalypse is a disruption for a transcendental process towards an Absolute which is impossible; a cessation, manifesting neither a succession nor an interlude but an utter terminus for transcendental Absolutism. Islamic Apocalypse is a momentary process for dismantling all manifestations of Absolutism, only highlighting the absolute externality of God as the Imperceptible or irreducible exteriority – 'The secret of God is eternally ungraspable by Man'; the Quran does not speak about the concealment of a secret but of the utter inaccessibility of the radical externality of God. This latter always remains secret, not in the sense of a mystery [*muein*] whose accessibility varies between the initiated and the uninitiated and according to the epistemological tools at ones disposal, but in the sense of 'being ungraspable and unthinkable forever' for everyone. According to Islamic scholars, it is the limitless generosity of this externality that, despite its radicality, makes 'being' possible for Man by posing itself as refractory impossibility. Theology in general, particularly Christian theology, is vigorously involved with the act of giving or the biblical *didômi*, and the measure of this act is determined by the emphatic limit of the act of giving in the sense of the Divine which is Revelation, or the epistemological Gift. The Gift of Revelation – by the necessity of the aforementioned affordable structure of Revelation – abstains from excess and ceases to be radical in itself and in the act of donation. The principle of gift-economy consolidates around its compensability. When a gift is afforded by the receiver of the gift, it can also – potentially and by virtue of the capacity of the receiver who has already met the expense or level of the gift – be paid back or re-gifted at least with a gift of equal or lesser value. When the gift is Revelation or the ultimate giving and Man is the receiver, the potential re-gift is proportionally equal to the possibility and the existence of God (*Esse*) itself in Revelation. The radicality of the gift originates from its exorbitance (it is outside the cycle of exchangeability), the absence of any opportunity to counterbalance or compensate it, and its externality to satisfaction, hence reducibility to a content. In Islamic theology and according to explicit Quranic verses, the ultimate gift from Allah averts satisfaction and does not satisfy Man in terms of providing what the human deems enough (*satis*). Nor can it be exchanged or compensated. Allah's gift attests to the immensity of the ultimate act of giving: the ultimate gift is essentially external to possession and possessability. If Allah's gift were to satisfy, or position itself as exchangeable, it would bring human being to extinction, an epistemological inferno and an ontological eradication; the gift then would contradict the act of giving and its giftness by becoming the act of absolute seizure or abolishment in the name of confiscation. The gift is merely the disclosure (in terms of unfolding) of Allah's externality on a radical and all-encompassing level, the affirmation of refractory impossibility and the repudiation of the possibility of an *apocalyptio* (unveiling) of a content, whether of God or of Man, which again should be differentiated from the content of the Divine in the usual understanding of Apocalypse. Disillusionment is the function and realization of such a gift. Islamic *Ghiamat* manifests enlightenment under the holocaustic luminosity of radical outside, and presents human possibility, of both ontological and epistemological potentialities, in the wake of refractory impossibility.

To this extent the monotheistic belief – *hena theon*, *unum deum* – does not describe a rewarding destiny in Islam; it submits the *cogito* to an externality for which belief is at the same time a plethora of uselessness and a minimally organized line necessary for attaching to the eradication of itself as it blindly pursues the eternal Unrevealable. Islamic Apocalypse is an anti-absolute politics. God is the only Unconditioned; it is neither grasped nor unveiled and thus cannot 'come into being' transcendentally; it is eternally external to Man, it is the Absolute as the desert of un-restriction (*ab-solvere*) for which Man or ontological potency is a restriction, a *modus* and a deterrent. Upon such an unfathomable externality, Man is left deserted; yet he is not abandoned, for this externality is mapped as an extra-proximity, utter and ungraspable closeness ('We are closer to him than his jugular vein' – thus the Quran). This is a panorama similar to the Survival Economy (*libban*, of Germanic origin) or what is commonly called life but is the territory of living (afforded Life or the process of affording life) and (un)Life, or life in its externality to affordability. Life is external to survival yet survival is allowed to live by means of the very 'possibility of containing' – or capacity – that Life makes accessible for it (either for the eradication of survival or in order to lure it elsewhere). What is given to Man is precisely what unlives for him. According to Islam, Man is liberated in *Ghiamat* not by joining the divine but through a disillusionment from his own being, a disillusionment made possible by the externality of God not the quiddity of this externality (*i.e.* the *Wesen* of God). *Behold the Outside, you shall not explore it*! For such an openness comes forth as a reactionary extinction by and through being, an inevitable self-destructive repercussion triggered by the affordance of capacity. But its unfathomability can be grasped; this indeed is the way that 'Return to God' is depicted in Islam. According to Islamic commentators, *Ghiamat* (the Insurgency) – which, again, is wrongly translated as Apocalypse (the moment of uncovering or revelation, *apocalyptio*) since even in *Ghiamat*, Allah is ungraspable and unrevealed to Man – promises a simultaneously brutal and glorious encounter of Man with what is radically external yet closest to him; awakening this externality for Man and awakening Man to grasp the radicality of this externality – the Unrevealable, the irreducible, full-fledged horror.

Revelation is extruded from the dynamic vector of a 'loving to know the unknown' as Augustine suggests, but not a loving of the unknown itself. In Islam, however, the Unknown itself is venerated in its full externality to the *cogito* and to love. Reverence then is influenced by an *outsiding* glory (radicality of outsideness) as an affect passing and emerging through existence, not in the sense of an advent or arrival from an outside which affords a tendency, that is to say, a constraining extension, but as a perpetual foreigner. Advent can only be registered as an event when it is fulfilled or reaches its tendency, a status where its foreignness ends (arrives at an orientation). Anything that has the quality and movement of an advent is bounded by a condition and a destination corresponding to that condition; its outside-ness is only provisional. To approach an unattainable without anticipation of reaching it and in the absence of a destination as a position to be possessed, the movement and its affect must be inherently upheld in relation to *xenos*, as a resident but ceaseless outsider (*xeno*) – insistent alien.

When the Unknown is unknown because of its radical externality, not because it is superior to human knowledge[13] – a position which can be afforded if not communicated or fully identified in itself – epistemological disciplines, in the same vein, unfold as alien tools. For such an unknown imbued with refractory impossibility, mysticism or contemplative theology proves itself to be not only otiose but a romantic project, a symptom of the loss of hope in a rigorous encounter with radical externality. If mysticism culminates in the form of an epistemological salvation or deliverance through initiation, its principles are constantly refuted by refractory impossibility, as simultaneously pusillanimous and irrelevant exploitations of ignorance on behalf of a redeeming unknown.

> 'Apocalypse' is a genre of revelatory literature with a narrative framework, in which a revelation is mediated by an otherworldly being to a human recipient, disclosing a transcendent reality which is both temporal, insofar as it envisages eschatological salvation and spatial insofar as it involves another, supernatural world.[14]

---

[13] The latter is exemplified by the theologies of Augustine or Aquinas. ('*In finem nostrae cognitionis Deum tamquam ignotum cognoscimus*' [Thomas Aquinas, *Boetium de Trinitate*]). Following Aquinas who did not pursue the heretical trail of his remark and did not travel to the outer limits of his theology, one comes to this conclusion about the Divine as the *superiora* of knowledge: that 'God exists as ignorance'. This does not denote that God is ignorant or is ignorance in itself but that God existentially registers itself in human knowledge as Supreme Ignorance. Therefore, the true existence of God as the ultimate knowledge (immutable wisdom and knowledge in its full presence) is dependent on human knowledge or real ignorance as something capable of being transcended, if the God's true face is to be unveiled (namely, 'God as ignorance' realized as 'impeccable knowledge').

[14] John J. Collins, 'Introduction: Towards the Morphology of a Genre,' in *Apocalypse: The Morphology of a Genre*, ed. John J. Collins (*Semeia* 14, 1979), 9.

Schelling's obsession with Revelation (*Philosophy of Mythology*, *Philosophy of Revelation*) which re-presents the Judaeo-Christian account of Revelation and is a pivotal *quodlibet* in non-Islamic monotheistic religions, is rendered completely obsolete in the Islamic account of Apocalypse (*Ghiamat*) and is regarded as heresy. It is described by Schelling as 'that which exists [...] only in order to see if I can get from it to the divinity'. Such a statement is based on the primal prophetic promise of Revelation, the promise that the divinity must be eventually revealed or exposed to Man through transcendence and its anabatic movements. The true glory of the lord is exposed to Man when it is revealed ['God can be known'(John 1:18; 14:7; 17:3,6)]. In Islamic Apocalypticism, such a promise is absent and is regarded as *Kufr* (apostasy). Motahari, the Iranian Islamic scholar, once suggested that the glory of Allah bursts forth at the exact moment when Man realizes that nothing of Allah can be revealed to him. According to Islam, in such a moment one encounters the utter mercifulness of God, for if God reveals itself, all modes of survival and being would be rendered impossible. If God were to reveal itself, everything would be overkilled. According to Islam, the most merciful moment (supreme glory) is the moment when Allah shows Man that despite its utter externality to all beings, they exist precisely by virtue of this externality. Allah's radical supremacy is delineated more according to its degree and radicalness of externality and openness than to its authority over being (According to Islamic literature, Allah does not need to enforce authority; authority is the consequence of this externality which maintains the survival of all beings for if Allah reveals itself, the undoing of Man will be inevitable).

On the topic of external sovereignty, Islamic scholars pose the question: if God is external and sovereign, then how can beings exist? This question is answered by recourse to an ungraspable generosity (not forgiveness) and Glory (both of which are purged of any quality) which surge up through beings as the only reason for their existence. Even the purpose of this Mercy and Glory will remain unknown, Outside: nothing of God itself will be revealed. With the consequence that applying the term Revelation (*apokalypto*) to the Islamic account of Apocalypse is highly problematic. Even on a technical level, Apocalypse, constitutive as it is of monotheism, is not designed for or capable of the particular functions that it presents in other monotheistic threads in the Last Day. *Ghiamat* (or *Qiyamah*), whilst it includes the diametric discourse of the Judgment Day and its monopoly on inevitability, as Al Faruqi points out, also adds a new and radical twist to the Apocalyptic politics common to all strands of monotheism; *Ghiamat* does not mean *apokalupsis* (involving the process of lifting the veil). Rather, it heralds *Ghiam* or rebellion, which is connected to *Sura Al-Takvir* (overthrowing). The Quran depicts *Ghiamat* – Ultimate Insurgency – as being governed not by a climax-oriented narrative, based on the consumption or depletion of the number of its possibilities, but on a series of participations, a chain of minor insurgencies (*ghiams*) which bring with them possibilities external to the capacity of the narrative.

Al Faruqi and Alameh Tabatabai both suggest that the Quran wholly withdraws from the diametric concealing/disclosing revelation of other monotheistic

Books, from the opening verse through to the end. It declares itself as an active cipher; it even shows a radical cynicism (or even hatred) for the facsimile by twisting the very foundations of monotheism as expressed in the Bible or Torah, progressively making itself unidentifiable, connecting what has already been told to anonymous (both in the sense of *an-onoma* and *a-nomos*) lines which make its contents accessible through an ulterior structure. This deviation from the familiar path culminates in the nomenclatural system usually associated with the Last Day; *Ghiamat* (Ultimate rebellion, Insurgency, Standing to respect, Awakening in the sense of disillusionment) becomes the substitute for all other names in Apocalyptic literatures which frequently suggest revelation (with *velum* at the center), resurrection or strict judgment (functioning through the dynamic scaling and measuring processes of *metron*).[15] The unity of the Advent Hope is frequently expressed by such phrases as 'the last days' and 'the end of the age'(Heb 9:26). Apocalyptic thought apparently arose within Judaism following the sixth century Babylonian exile of the Jewish people. Although the book of Daniel is the only complete example of an apocalypse in the Hebrew Bible, other passages contain ideas that are either apocalyptic or similar to apocalyptic thought – Examples would include Zechariah 9-14, Ezekiel 38-39, and Isaiah 24-27.

---

[15] *Metron* (Greek origin), to be found etymologically encrypted in English words such as Dimension (from *dimetiri*: measure out), meter, etc. Keeping well in mind the famous doctrine of Protagoras, 'Man is the metron of everything' (*pantôn chrematôn metron anthrôpos*), *metron* can be translated as Scale, Measure, Standard, and Value. According to Sextus Empiricus *metron* expresses *criterium* (scale, measure) but Heraclitus and Sophocles saw it as certifying dominance, a domination over something. Therefore, *metron* indicates that both measure and dimension interconnect with Power, Justifying and Reasoning. The critique of *metron*, then, diagrams how dimensions (namely *metron*) bring Power into effect, mobilizing and propagating it.

In Islam, and particularly in Sunni accounts of Islamic theology, examples of revelatory apocalypse and even seeing Allah in *Ghiamat* can be found (Abu Hurairah, Al Bukhari, Al Hajjaj, *et al*). However, most of these apocalyptic attributes originated from Hadiths – and hence had been subject to alteration, hadiths having being collected in different times and by different narrators. Their authenticity being thus questionable, they could not maintain a lasting presence in Islamic theology and Islamic accounts of *Ghiamat*. Not only because of their disputable origin (as in the case of Abu Hurairah for example), but also because of their contradiction of the emphatic statements in the Quran regarding *Ghiamat* and absence of revelation, in Islam apocalyptic theology (in the sense of revelation and epistemological or ontological unity with God) did not succeed in extending its influence beyond classical and early Islamic theology. In Islam, explicit reference (*nas-e sarih*) to the Quran is prior to everything and must not be transgressed. Cultivated by the Al-Azhar School's rigor and animated by such figures like Mahmood Shaltoot who inveighed against the classic theologians who advocated apocalyptic eschatology of Judeo-Christianity and worked mainly outside sectarian doctrine, the revelational doctrines were denigrated in Islamic theology.

---

16. *Apokrisis* or *ekkrisis*, the Anaximanderian universal pro-creationist process of separation which is a prerequisite for unification and ultimate union. The process of *Apokrisis* stratifies the universe into properly arranged layers (unlimited appropriation and regulation by lamination and stratification) which make unification as a dynamic process possible. This process of separation is prerequisite for the cosmic union/separation machinery of the ultimate unification, or in other words, the final union which functionally presupposes a series of separations and unifications leading

The externality of Allah cannot be oversimplified into a mere process of separation (*ekkrisis*).[16] Aristotelian philosophy shows us that separation always presupposes a unity through a cyclic transcendence of separations (of *chorismos*) and unions (of *to hen*) which rotates – or in more technical terms, refines itself – towards a distilled Quiteness or Unity with the Divine, a unity which is not present in Islam. Moreover, unlike other modes of monotheism, for Islam this externality is not the result of a primal moral collapse or original sin (the Revelation system of Christian redemptive history influenced primarily by Tertullian [ca.155-220]); it is intrinsic to the existence of being. Neither does this externality have anything to do with sinfulness or the concupiscent nature of Man – who in Judaeo-Christianity must be cleansed, introduced to *katharos* – since in Islam the present condition of Man is not sinful but normal; in the Islamic account, sin emerges only as a consequence of the mis-perception of this externality, as a result of latching on to the quiddity of this externality, Allah.

Islam does not construct itself on redemption and/or revelation. Redemption (the wayfarer becomes totally at one with God's way of redemption) is inseparable from its consequent hope and boredom or redeeming despair, and modes of development which are steered by the conjunctive bonds between these two. The promise of

---

to a purely distilled Unity (corresponding to the classic distilling mechanism). Anaximenes, however, developed the process of *ekkrisis* into the two processes of rarefaction (corresponding to separation) and condensation (corresponding to unification); we can follow these processes in the unificatory and distilling mechanism of Kerotakis (reflux condenser) which was invented and designed according to the cosmogonic traditions of alchemy and Aristotelian philosophy. On *Apokrisis*, see Theophrastus commentaries on Anaximander; also, Hippolytus' *Refutation.*

Revelation presupposes a reward for a vigorous transcendentalism through the loss of sin and the accomplishment of unity with God – or more precisely, the reformation of affordance, and the capacity of Man to turn the (latent) impossibility of the Unity with God into a possessable possibility. In Islam there is no such reward, no such promise; there is only the inexhaustible activeness of refractory impossibility or Absolute Openness, crushing affordance and the economic regulations of capacity, disillusioning Man from his repressive openness *qua* economical self- and environment-protecting communication. Externality is diagrammed by a simultaneous formidable closeness and externality of function, a concretization of 'closer to you than your jugular vein' (what a vampiristic horror!)

IN ISLAM, CHRONOLOGICS IS A HERESY.

> The individual's encounter through faith and grace with a personal God then salvation is contained precisely in the human surrender to God (*Islam* [Submission]) and that divine guidance (*huda*) which according to the Koran remains or should remain forever unaltered by time and history. Accordingly, there is no reason to conceive of revelation as something temporal or historical.[17]

Norman Brown is right to suggest that Islam is thoroughly apocalyptic but without a sense of 'Time' that could be grounded as the ordinance and understructure of the spectacles of Grand History (whether *Heilsgeschichte* or

---

[17] Abdoldjavad Falaturi, 'Experience of Time and History in Islam,' in Annemarie Schimmel & Abdoldjavad Falaturi (eds.) *We Believe in One God* (London: Burns and Oates, 1979), 65.

Weltgeschichte). 'Only the moment is real,' Brown notes,[18] but goes no further. The moment is transient, its function is traced by its escapability, momentary variation and particle frequency, by its *gradus sine vestigio*; the moment in its entirety is an *uncogito* with a pulsatory intermittent existence, ungraspable by Man and inaccessible by mapped courses of action. All that is graspable are the moment's trajectories, its tails which complicate and diagram time according to their spatial multiplicity, rather than the chronologics of Time. Too many traces left by the ever-escaping moment result in the loss of time, 'untraceability of all narrative lines and temporal relations'[19] (= The Islamic Apocalypse, *Ghiamat*), the fall of the Kingdom – the emergence of a sinister imminence constructed not upon temporal relations or modes, but upon the loss of them. Such a constant imminence surpasses necrocratic terror: when Omega is always imminent and one cannot look backwards and ask what happened, the necrocratic fear of death – powered by anticipation of the future as well as the questioning of the distance to the Outside – is but a neutralized repression.

Time is absent in the Quran; the absence of any occurrence of the word *Zamaan* (Time: *chronos*) is one of its most noted enigmas. Instead of using the word *Zamaan*, the Quran frequently addresses events through the word *vaght*, conveying them through *vaght* and not *zamaan* towards *Ghiamat*. *Vaght* is concerned with 'Whereness' whilst also obscuring the quiddity of this whereness as spatial but unlocalizable ubiquity; it can only suggest an unchronological Now (neither permanence nor discontinuity; all entities are regarded as events through a denuded space with no chronologic dominance), a 'timeless where' through which beings are suspended but not stopped. But 'Where is Now?' The Quran never answers. 'Now' always remains anonymous; its ever-expanding Where which is essentially based on its whereness (the quality of its spatial continuity), is ceaselessly contagious. For whereness engineers terrains to remain ubiquitous and be actively divergent, a multiplicity which is a manifest epidemicity. Where is intrinsically and autonomously contagious. All manifestations of history (or even histories) are regarded as an infidelity towards this spatial and contagious Now (*vaght*) which is the most functional plane for utter submission (*Islam*) to the eternal externality of Allah, the pervading or epidemic impossibility. *Now* is the only plane on which Being can be saved from complete extinction by its illusions, which foam around its grand obsession with unity. Abdoldjawad Falaturi is possibly the first Islamic commentator who has rigorously worked on *vaght* in the Quran and on the Islamic sense of time (See his *Experience of Time and History in Islam*, and other essays).

---

[18] N. O. Brown, *Apocalypse And/or Metamorphosis* (Berkeley: University of California Press, 1992).

[19] Norman Brown writes, 'the Quran breaks decisively with that alliance between the prophetic tradition and materialistic historicism – "what actually happened" – which set in with the materialistically historical triumph of Christianity.' (*Ibid.*)

In the sense of *Ghiamat*, is it too early or too late? Only by your 'participation' with this spatial Now (*vaght*), can you find out. We are always in a premature *Ghiamat*.

Islamic imminence escapes the doctrine of the Advent and the Christian Imminence. 'The great day of the Lord is near and hastening fast'(Zephaniah 1:14); 'O Sovereign

Lord, holy and true, how long before thou wilt judge and avenge our blood?'(Rev 6:10): such Nearness or Distance is at the heart of the Christian imminence, architectonically constructed on Waiting and Patience ('Be patient' [James 5:8-9], James admonishes believers). The affordable *esse* of the Christian God posits the Outside in terms of distance or opening-between (an openness that is situated in-between is affordance rather than openness). Distance and affordance realize movement only in the anticipation of reaching a destination, even if the destination is not accessible and only exists as an affordable event or entity. In terms of economical openness, what is afforded has already been achieved with the same scale of possibility and actuality. If distance potentiates destination, and destination actualizes distance, a movement that either travels according to the distance or according to and towards the destination would remain passive in its dynamism, because it would have already been presupposed by affordance. Such a movement, one whose course has already been afforded, does not undertake the risks of venture, instead it accepts the consequences of anticipation (immanent to distance and the afforded movement). Here opens a horizon of passivity as the inexorable glorification of patience and chronological toleration organized by the promise of Revelation, as a moral urgency of the Advent and Revelational Hope. Or, to be exact, this nearness of the Christian Imminence is articulated by the passivity of waiting and patience as the consequences of anticipation, whose endemic affliction is expectation, which in turn provokes hope and negative despair and gives rise to crises of faith (as for the first century Christians who expected the grand return of Christ: '"My master is delayed," the unfaithful servant complains'[Matt 24:48]). And it is through this prolonging of hope and persistence as to the affordability of openness (of both Man and God to each other), that faith is manipulatively maintained. To this extent, the distance (wait, patience, nearness, expectation) of Christian imminence can be *metron*ed (measured) either by Empirical or Existential Time. But Islamic imminence, spread over the epidemic Now, has no such bond to expectation, patience or waiting, and it cannot be measured since it is entirely based on furious participations (voluntary and involuntary, triggered by total openness fueled by a refractory impossibility that cracks affordance *ab intera, ab extra*) moved by the loss of the promise of the Revelation and the eternal externality of Allah.

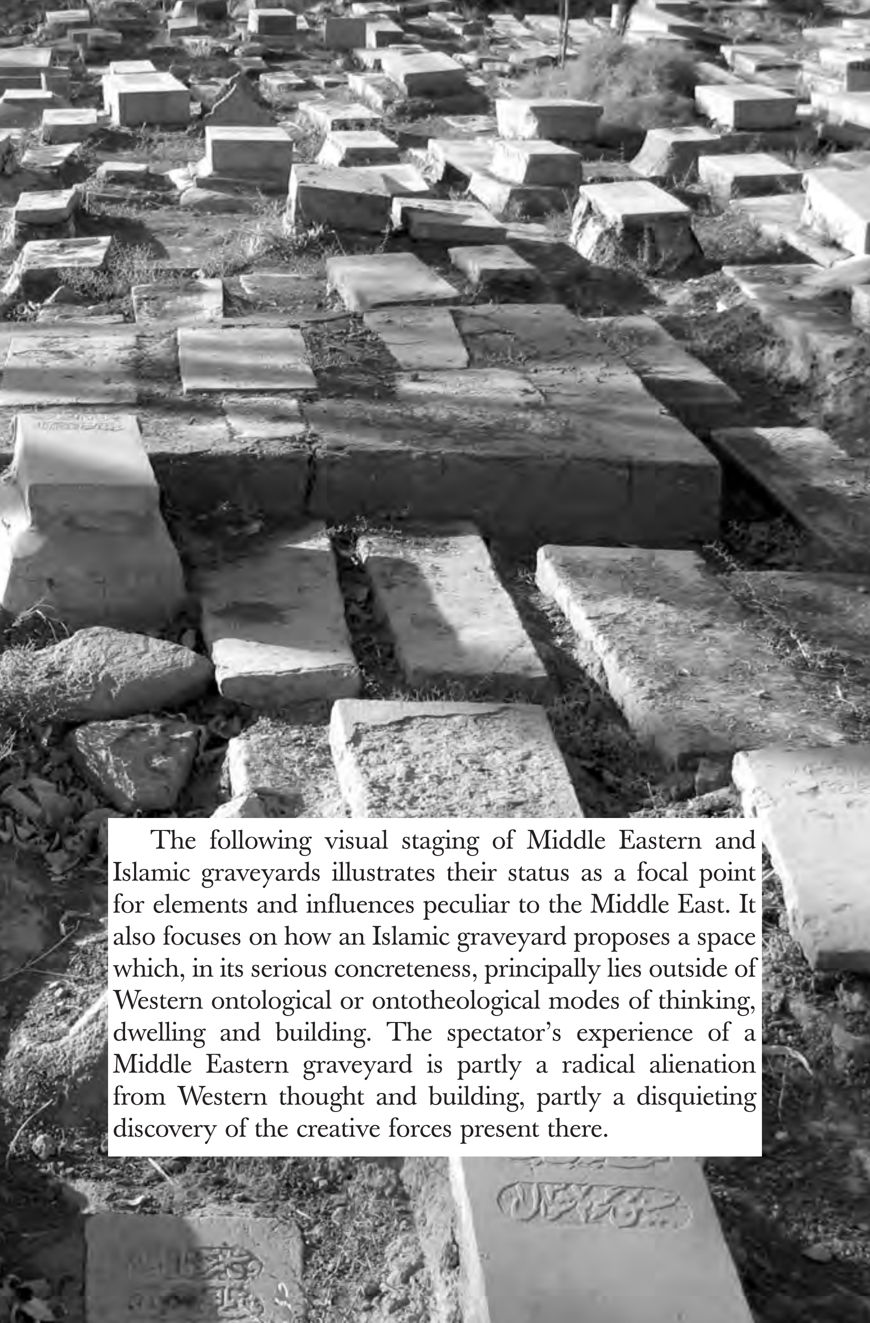
If Islam's process of submission affirms the radical externality of Allah as a refractory impossibility, and if Islamic Apocalypse supposes the loss of time, then for Christianity, Islam expands and inflames along the same chronopolitical dimension in which the Apocalypse deploys its cremating and concluding machinery, incinerating the western sense of time, cleaving the bonds between modes of historicity and western chronologics; a plane along which chronologics shrinks to momentary particles taking viral and swarming forms to spread through this spatial Now (or irrevocable imminence). Islamic *Ghiamat* is the vertigo of moments. For Christian chronologics, Islamic chronopolitics is that 'radical disruption in the spatio-temporal relevancy of events' which is generally called the Apocalypse. If War on Terror, on its western front, is haunted not by *fin de siècle* scenarios but also by the political manifestations of the Apocalypse and emphatic finality, it is because western chronologics has engaged an opponent which only exists as a desert levelled of all idols or transcendental abominations to Allah. It is the desert that hosts, and looms as, the Apocalypse. It is a desert lurking in the disruption of chronologics, the corrosion of history and the collapse of the spatio-temporal continuity to the outside, because it is effectuated by refractory impossibility, not the other way around. This is not a question of a clash between civilizations but a radical Time-war, between chronologics and chronopolitics or what – by virtue of its dynamism, that is affected by the Outside and Impossibility – operates as Apocalypse or time-disruptive politics within other systems. Each Western tactical line in War on Terror must inevitably configure its program with reference to Islamic chronopolitics if it seeks to engage and afford the 'conflict principles' (correspondence with other war machines in space and time) which every war machine both upsets and affirms. If, on the Islamic front, the *Ghiamat*-apocalypse is always already-there and the entities of the *pax islamica* are already desert-nomads of this contagious Now, for the most part (but not entirely) it is the Western entities of War on Terror which are subjected to apocalyptic commotions and disruptions in time. While the Western chronosphere harbours a chronological cataclysm for the Islamic front, Islam's chronopolitics betrays time and the Western chronosphere altogether.

Elysian Space in the Middle East

Kristen Alvanson

ONTORIUM. *The Western graveyard is a place of consummation for the ontotheological horizon which dominates Western engagement with time and space. The site of the graveyard bridges the ontological contents of the living and the* post-mortem *protrusion of these contents, thus marking the transition from ontology to theatrical ontology. Or, in other words, here ontology is staged both as it is – or as it functions – and as the result of its own accomplishment (effect). Thus, all ontological projections of architecture flourish in the graveyard. Taking into account Heidegger's notion of 'settling'* (regelung) *which, from both objective and subjective perspectives, describes the connectedness of building, being and thinking, the graveyard, then, is a rich resource for reasoning back to the experience of the ontological encounter with space and time and the uniqueness of this experience within each culture or ontotheological formulation of Elysian Space.*

COLLAPSE II, ed. R. Mackay (Oxford: Urbanomic, March 2007)
ISBN 978-0-9553087-1-2
http://www.urbanomic.com

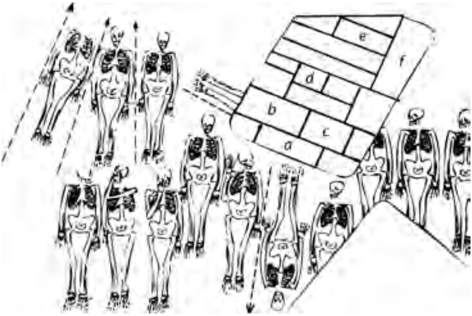


The following visual staging of Middle Eastern and Islamic graveyards illustrates their status as a focal point for elements and influences peculiar to the Middle East. It also focuses on how an Islamic graveyard proposes a space which, in its serious concreteness, principally lies outside of Western ontological or ontotheological modes of thinking, dwelling and building. The spectator's experience of a Middle Eastern graveyard is partly a radical alienation from Western thought and building, partly a disquieting discovery of the creative forces present there.

MORE THAN A VOLUME, LESS THAN A SPACE. The Western ontology of dwelling has it that *residing* (remaining) alone in a space which both separates its dweller from, and connects them to, their surrounding environment, is not in itself enough to define dwelling. Therefore, residing or occupying cannot be appropriately integrated with building and being – and for that reason, with the human. Dwelling is the inhabiting and populating of a space by an entity. This definition requires an axial factor which is sustained by an entity and its dwelling place; a factor that can be defined as ‘the minimum space required for the inhabiting and populating activities of a given entity in a given place’. The basis of these activities is movement. The dwelling-place, or room, is a space in terms of its capacity to accommodate contents or allow actions. What is required for such a definition is, firstly, a volumetric instance of building that can support both an entity and its actions, or

more specifically, its movements within the space. The consequence of dwelling, then, is more than mere inhabiting; it also includes different actions provided by this ‘enough’ space or room which fundamentally takes shape and is built upon the minimum, that is, the minimum space. According to this ontology of dwelling, then, the human as a dweller builds its action on a limit which is that of the minimum, and which is maintained in every ontological context related to (the) *room.* Western graveyards push this ontology of dwelling to its extreme. Such an ontological orientation only makes sense when an onto-theological disposition of dwelling in its fully-fledged sense is involved; for otherwise, the application of the dwelling ontology of the living to the dead would merely signal the reduction of ontology to law. Sarcophagus and coffin as above-ground and underground volumetric spaces of room are examples of this ontology of dwelling that is manifested in Western graveyards and entombment. Similarly, the required limit for dwelling or room as 'enough' space entails not only an adequate space within each grave but also between graves, determining an orderly arrangement in the graveyard.

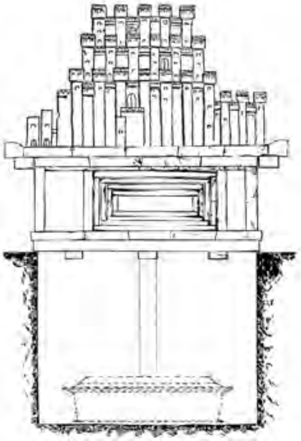
Proximity, Privacy and Neighborhood. In Middle Eastern graveyards, graves randomly infringe or interfere with each other's affairs and private space. The openness of graves is only superficially restricted by the size of the horizontal grave slabs and their boundaries. The slabs are commonly used as markers, as opposed to vertical tombstones. Neighboring grave slabs or horizontal markers form a relatively uniform surface, a solid flatness as opposed to a volume. If the Middle Eastern graveyard exhibits a single ambition, it is that of partaking of and sharing flatness. Socializing with the dead in Middle Eastern graveyards is partly inspired by the elimination of 'room' or sufficient space of dwelling. In order to reach loved ones, a visitor has to walk over neighboring graves. Greco-Roman graveyards maintain a type of dwelling or



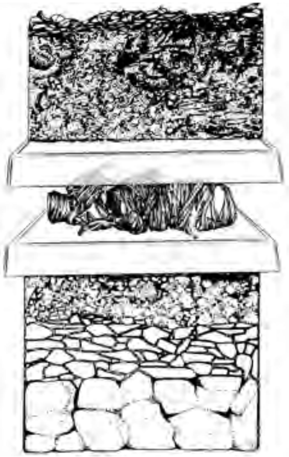
adequate space for the living and extend the dwelling space of the living to the dead via a law-abiding transition of ontology to the ontotheology of the living. The reason for Western culture's preoccupation with the roaming or walking dead can be found in the establishment of the graveyard as a residential complex, a settlement which the dead should have no reason to abandon. In Western graveyards, the space of graves can be given as a metric value, each person being allotted relatively equal space for their grave and its surrounding. In Islamic graveyards this space varies: some graves are inches away from each other, others slightly further; many are buried on top of each other, as new cemeteries are carpeted exactly atop older ones. Sometimes five layers of new cemeteries – as in the case of Iran's *Dar-o-Salam* graveyard – bear each other's tombstones, graves and their contents; only the most recent graveyard is visible, while the rest form the bedrock of the new cemetery until rain or soil change force a small part of the older graveyards to surface in an unexpected place, sometimes beneath a recent tombstone. Thus the

hadith that 'no one can build any palace or even a house other than on top of someone else's home' is exemplified in a typical Middle Eastern graveyard. The *hadith* aims at the nihilism of economy or its impending fate, because this is understood to lead to a tranquilized economy. If layers and layers of graves over each other – in addition to the literal contact of graves and their horizontal slabs – have one ontotheological message, it is the intimacy of the living with the graveyard, the dead and their own demise.

Elysian or Emphatic Horizontality. Western coffins or burying spaces are by their nature sarcophagi. They are governed by the fate of volume: providing room. Western graves bespeak dwelling space on two levels: one is the coffin or casket which provides its contents with room; and the other is the surface tombstone or perpendicular marker that represents a volume. The difference between Western and Middle Eastern – or specifically, Islamic – graveyards in their approach to building originates from their difference in grasping or working with the solid as a building or architectural component. If, for the Western graveyard, dwelling is supported by solid volume, or the solid that brings space to volumetric enclosure, for the Islamic graveyard the solid subtracts dwelling from the volume. In Islamic graveyards, solidity is the privileged state of matter; unlike its role in the Western graveyard, where it creates volumes, it is replete, and has only one role: to remove room or adequate space for dwelling from the grave. The body in an Islamic burial is not placed in a coffin; coffins are used only by family and friends when carrying the deceased to the grave site. The body is placed atop a solid stone slab deep in the ground, tightly wrapped within a *kafan* or shroud sheet. Another slab of the same size is put over the body to fully press its weight on the deceased, crushing the chest and eliminating any space or air around the body. Then dirt or soil is dumped on the slab, swallowing the body into an Elysian horizontality which is that of a filled solid without room. Finally, another slab is placed on the surface to conclude this Elysian horizontality for the living.



In general, then, graves in Islamic graveyards have no 'dwelling' potential. Heidegger ties building and dwelling to the twofold of thinking and being. Thinking is entailed by *raum* (room) or dwelling space. In the wake of the Western graveyard and its ontological dwelling-space, continuing as it does either on the ground or under the surface as in the coffin, the Western aspiration for thinking is carried on even beyond death, in the grave. The act of removing the dwelling-space in Islamic burial leaves no space for thinking. The Elysian space of Islam creates spaces which, by virtue of their resistance against the ontology of dwelling, subtract the creative force of building and being from the Western exigency of thinking.



Unlike the comforting Western spaces, the slabs of the Islamic burial exert pressure. Their emphatic horizontality rises from bottom to top, diminishing *post-mortem* relief. The two slabs under and over the body transmit the hardness and the weight of deeds in life. These weights create a crushing force which makes use of tolerance and turns it into pressure; because sin (pressure) reaps its potentiality from tolerance. When tolerance reduces, or one becomes less tolerant by various means, such as temptation or loss of hope, sin ensues by virtue of this lack of tolerance. Yet the dead have no

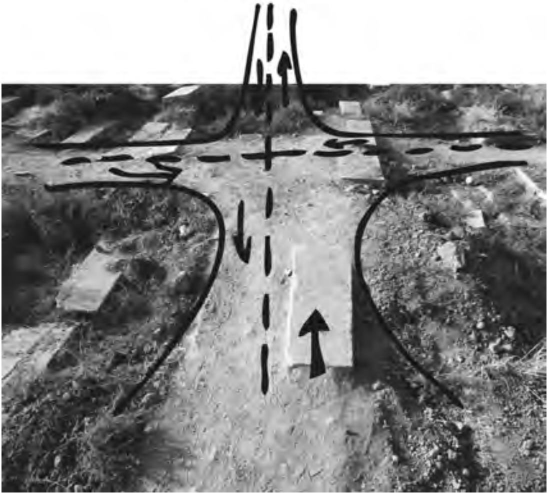
tolerance. If theology nourishes faith by being well-grounded and valid to the very End, the Islamic graveyard deals with a theology thatmaintains faith by purposely stopping making sense.

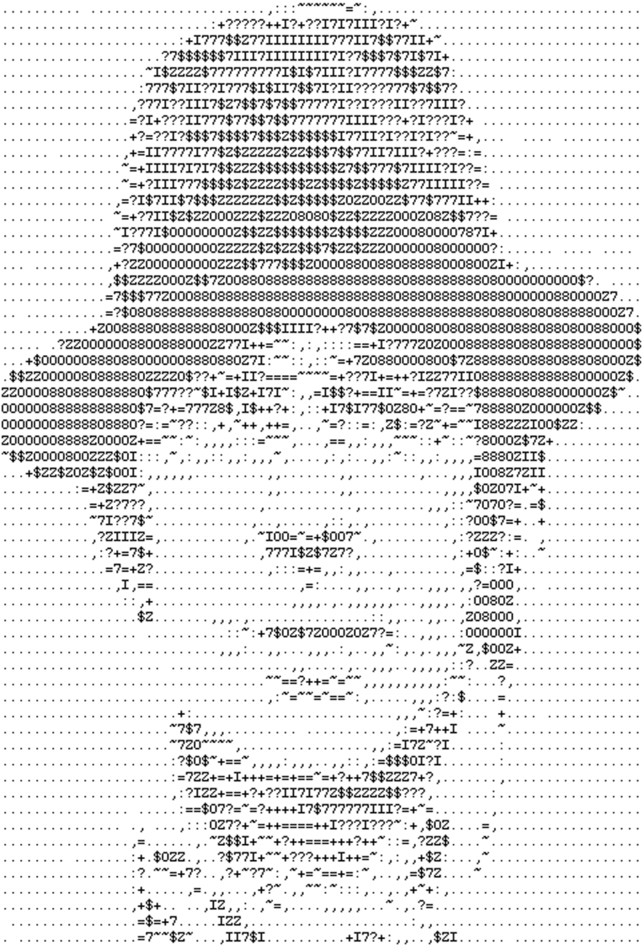
Over one's dead body. An Islamic graveyard encourages an uncommon socialization with the dead. The dynamics of this socialization are for the most part inspired by the building forces of the graveyard. If the dignity of the dead is nothing but the indulgence of the living, then the living too ought to be liberated from the legal codes that bind the graveyard to dwelling and traffic taboos. Firstly, everyone, regardless of religion or orientation, can be buried in an Islamic graveyard – as long as one can endure the place. In the Middle East, the graveyard is fully connected to the social body; it is located in the vicinity of social activities. The Islamic graveyard is a place of casual socialization. Fruits and snacks are brought to the graveyard to be distributed among the poor. The poor come to the graveyard to eat and return to the communal structure of society. The graveyard levels the dead as well

as the living; privatization of the space around graves rarely happens. When it does, it is to construct a shade over the horizontal slab to protect the marker from the sun. If in the West, graves represent private spaces even when they have no walls built around them, in a Middle Eastern graveyard this private space is casually broken by people walking over graves. Tens of footprints on each grave mark the evidence of this passage from restricted dwelling to collective wayfaring.

Lastly, the graveyard is trans-gender. In the Islamic graveyard, the faces of deceased women are often rubbed off from the photos which are placed on their graves.

Given the fact that historically in Islam, the face of God and holy figures must not be depicted, and vermin are faceless people, removing the faces of women amounts to verminizing the Divine, or making God and woman equal.





Computer Deleuze

Editorial Introduction

Robin Mackay

Welcome to our third volume, the greater part of which is devoted to the work of Gilles Deleuze.[1] Alongside a number of searching examinations of his work, it also features two previously untranslated texts by Deleuze himself. Although assembled under the working title 'Unknown Deleuze', the volume announces no scandalous revelation, no radical reinterpretation; rather, this title simply indicates a humble acknowledgement of the fact that, *philosophically speaking*, Deleuze remains something of an enigma.

It is not without trepidation that we devote almost an entire volume to one particular philosopher; even more so given the ever-accelerating trend of secondary commentary and the rash of titles claiming to apply Deleuze's thought to

---

[1] In the second part of the volume we present a record of the conference 'Speculative Realism', which elaborates certain themes taken up in COLLAPSE Volume II. Since these themes were already introduced in that volume, we will remark here only that one should not anticipate a discursive statement of fully-formed philosophical positions, but rather a continuation – in the absence of the extended interviews featured in previous volumes – of COLLAPSE's commitment to the publication of 'live philosophy'. 'Speculative Realism' is a conversation between four philosophers who think outside partisan affiliations to particular thinkers or schools, and thus is genuinely exploratory. Its 'unfinished' aspect reflects its status as a document of contemporary philosophy in the making, in which new conceptual approaches are proposed, the borders between science and philosophy probed, and the history of thought mined for fresh insights.

COLLAPSE III, ed. R. Mackay (Falmouth: Urbanomic, November 2007)
ISBN 978-0-9553087-2-0
http://www.urbanomic.com

areas as diverse as dance, feminism and geography. These latter might be taken as proof enough of the continuing fecundity of Deleuze's philosophy, but they belie the fact that it is still difficult to situate his work philosophically. Interdisciplinary appropriations too often compound this, turning 'Deleuzianism' into a game of recognition and thus merely succumbing to a new image of thought (*everyone knows* what a rhizome is …) Although doubtless such works can and do succeed in producing worthwhile and productive syntheses, it is difficult to assess their claim to represent Deleuze's thought without a renewed, properly philosophical effort to examine the latter. But should this even matter, given that Deleuze himself told us simply to use concepts 'like a toolbox'? Such a riposte typifies the most deleterious aspect of the 'success' currently enjoyed by Deleuze; for any precision tool must be mastered before it is 'put to work', and for this one must understand, in turn, its own workings and its interaction with the rest of the conceptual 'equipment' in hand.

The first of our texts by **Gilles Deleuze** himself, a short interview from 1981, offers a review of the enduring concerns of his ambitious philosophical project. Despite its brevity, the exchange merits translation because it sees Deleuze, despite his antipathy to being asked 'general questions',[2] speaking on a general level about his philosophical work, even going so far as to make a distinction – heretical by the lights of *Capitalism and Schizophrenia* – between his own concerns and those of Félix Guattari in that work. In this exchange Deleuze recapitulates and reaffirms the major themes of his thought – a renewed philosophy of nature; the problem of the image of thought; the construction of a science of the problem, and of a new metaphysics; the battle against neurosis and the typology of multiplicities. The other contributors to our volume take up, in various ways, the question of the interconnection of these themes – how do they come to be integrated into *a* philosophy?

---

[2] *Dialogues II,* 1.

With a style that combines the resources of the conceptual, the poetic, the mythical and the etymological, **Arnaud Villani** has constantly aspired in his work to do justice to the richness of Deleuze's thought, just as this thought itself, he argues, aims above all to do justice to the 'burl' of the real.[3] Gerard Manley Hopkins, who Villani cites here, is indeed an intriguing reference-point for Deleuze, with his language of 'inscapes' and 'instress', 'oftening' or repetition, and 'cleaves or folds' in the 'burl of being'; but it is Villani's aim, without annulling this poetic affinity, to distance Deleuze from any model that would have us rely on God's grace (Hopkins) – and equally, on the grace of the universal (Badiou)[4] – to take us from one 'cleave of being' to another.

For, as critics who attribute to Deleuze a politically suspect 'aestheticism' point out, it is in the practical sphere that an affirmation of 'life, in all its frightening complexity'[5] is not enough: this complexity must be negotiated, reduced, decided upon. Against charges that Deleuze falls short of this exigency, Villani emphasizes the importance of the moral and political in his work, arguing that the central problem of a Deleuzian metaphysics is that of 'isolating the conditions of possibility for a complex act'.[6] Indeed, Villani suggests that philosophy itself begins precisely when we try to think experience without sublimating its infinite riches by investing them in back-worlds. Succeeding in this would mean that action, no longer having a special status to whose strictures the poetic and noetic would have to be submitted, would multiply their infinite riches: like the sensible and thought, it would remain true to the 'burl of being' rather than fearfully ceding to a vicarious relation to it. Ethical action would not betray the infinitude of experience but would affirm it in its every work.

---

[3] A. Villani, present volume, 52.

[4] See E. Alliez, 'Badiou: The grace of the universal', *Polygraph*, vol. 17, 2005:267-73.

[5] G. Deleuze, 'Questions', present volume, 42.

Such complexity would not at all preclude action from being 'pointed', punctual;[7] only it would be a matter of an intense, implicated concentration rather than a decisive rupture: singular in the sense of the haecceity, the non-substitutable moment, rather than levelling all moments with a dis-qualified void. Here Villani pinpoints the most troubling consequence of the demand – increasingly made in respect of Deleuze's (and Guattari's) work – that a philosophy should prove its political mettle before even being considered as philosophy. This is a question of beginnings: in beginning with the infinitude of lived experience, Deleuze wished to see the 'drastical' rise to it; whereas in beginning with the demand for 'decision', we decide in advance against a truly philosophical – metaphysical – thought, thus impoverishing action and making political 'truth' the locus for an effect closer to the positive feedback of *hype*, drastically disengaged from the real, than to a 'labyrinth of creation'[8] with a 'thread' always connecting it to the outside, keeping it open.[9]

---

[6] Villani, present volume, 56.

[7] *Ibid.*, 58.

Why would a 'pure metaphysician' see a theory of artistic creation as an essential component of his project? Precisely because 'complex action' finds at least one of its models in the artist's attempt to endow the work – through a series of selections or decisions 'concerning for example the relation of two neighbouring colours'[10] – with the infinite complexity of his experience. This is the process that **Éric Alliez & Jean-Claude Bonne** detail in *Matisse-Thought*,[11] where they advance a radical new thesis with regard to Matisse's development – namely, that the 'Fauve period' was not a wild anomaly but a period of rigorous experimentation which laid a methodological groundwork for everything that would follow. In the process, they demonstrate the pertinence of a Deleuzian 'metaphysics', in the rich sense explored by Villani, to an alternative conception of modern art and, indeed, modernity.

Rethinking Matisse's painting as a practice of the 'all-over', in which the force of local actions is always determined in relation to neighbouring forces within a virtual 'whole', Alliez and Bonne recall the importance for Matisse of 'a complete vision' of this 'whole'[12] – not a formal blueprint to be 'transferred' to the canvas but 'an idea which one does not truly know except in so far as it develops with the growth of the painting'.[13] Their thesis is that the importance of Fauvism, for Matisse, lay in a 'strict quantitative ordering' by which it governed this processual development.

As 'the empirical exercise of sensibility [...] can grasp intensity only in the order of quality and extensity',[14] so the indissociability of quality and quantity indicates their mutual origin in intensity. The pursuit of the Idea in the processual unfolding of the work is not a quest for a particular contrast between 'a certain red and a certain green',[15] since these qualities mean nothing apart from their quantity; it seeks, rather, an actualisation (one of many cases of solution) in which the 'proportions of tones' (quantities of qualities) will act like a kind of lens, converging sensations in order to repeat or rehearse an Idea (*focus imaginarius*) in itself imperceptible since intensive.[16] The Idea of the whole does indeed come first, but its *expression* is assured only through a painstaking process of experimental *construction*.[17]

[17] In a recent book, film-maker David Lynch adumbrates the characteristics of this constructivist-expressionist conception of the Idea as infinite heterogeneous multiplicity, and its actualization as intensive unfolding of differences: (1)*All at Once*: The Idea as event or encounter, as a singular moment or haecceity (the Idea is neither foundational or generic, but is always encountered within lived series). Why does touching the roof of a car heated by the sun 'cause' the appearance of 'the Red Room […] the backwards thing […] and then some of the dialogue'? (2) *Fragments:* The encountered Idea is already partially unfolded into a set of sensible fragments, only ever encountered in a state of 'degradation', but this degradation is in its very nature in so far as it appears. (3) *Expression:* The 'adventurous character of Ideas' implies a dialogue, a continuing conspiracy ('The Idea tells you to build this Red Room. So you think about it. Wait a minute, you say, the walls are red, but they're

An early experience during Matisse's apprenticeship with Moreau shows how this problematic had exercised Matisse, from the very first attempt to copy a painting in the Louvre, Chardin's *The Pipe*: he was 'baffled' by 'an elusive blue […] a blue that could look pink one day, green the next.' In a strange, inverted prefiguration of his mature method, Matisse 'even cut up his own preparatory oil sketch and stuck bits on to Chardin's canvas, where each separate section was a perfect match, but when he put them together, there was no longer any correspondence at all. "It is a truly magical painting," he said, adding that this was

---

not hard walls. Then you think some more […] they're curtains. And they're not opaque, they're translucent. Then you put these curtains there, but the floor […] it needs something […]'). This pregnancy of the Idea, in the process of its expression-construction, suggests a new understanding of *anamnesis*: The retention of the singularity and the unpacking of its intensive differences 'incarnates' the Ideal event, so the work becomes the ground for repetition, rehearsal or recollection of what was inactual but was somehow encountered ('[…] you go back to the idea, and there was something on the floor, it was all there. So you do this thing on the floor, and you start to remember the idea more […]') The successive posing of questions operates an 'enframing' of the Being-Idea-Problem constraining it to bring forth 'cases of solution' (*b*eings) to which the former remains irreducible but without which it would remain the object of a sterile and mute contemplation (whether phenomenological or 'Platonic'). In this sense, and *contra* Heidegger, science, when it experiments, is no different from art, their estrangement merely responding to a conventional partition of Problems-Ideas on the basis of the apparent duality of quality and quantity, itself testifying to an 'image of thought' that capitulates to the covering-over of intensity or difference-in-itself. (The theme of *mathesis universalis*) (4) *The whole must be made:* This estrangement is dissolved in a 'superior empiricism': Ideas as experienced intensive states, in pure memory, employed in the assessment of an attempted repetition ('when you veer off, you *know* it […] this isn't like the idea said it was'), in ensuring a fidelity to the event through its mediate reconstruction (or retro-struction) through the manipulation of quantity and quality in an 'all-over' organisation ('The idea is the whole thing – if you stay true to the idea, it tells you everything you need to know […] You try some things and you make mistakes, and you rearrange, add other stuff, and then it feels the way the idea felt.') (D. Lynch, *Catching the Big Fish: Meditation, Consciousness, and Creativity* (London: Tarcher/Penguin, 2007).

the only copy he had in the end to abandon.'[18] Matisse was to pursue the reverse-engineering of this 'magic', the life of the painting, throughout his career – and this, as Alliez and Bonne show, through a meticulous and rigorous thinking of the dynamic relations between the intensive and extensive, quality and quantity.

That Alliez and Bonne see this new conception of painting as implicitly prefiguring a new political formation only makes more urgent the completion of Villani's 'typology of complex action': for does politics, can politics, really proceed in such a fashion (even if 'the factors of decision and prediction are limited'): 'by experimentation, groping in the dark, injection, withdrawal, advances, retreats […]'?[19] In any case, their analyses, like Villani's, are invaluable in uncovering the connection between what we might have understood as Deleuze's metaphysics *stricto sensu* (the typology of multiplicities, the necessity of the virtual, difference), his ethics (denunciation of the priestly type, active and reactive forces), and his aesthetics (the notion of *intensity* as infinitely expressive force). Rendering back over to every instant of life what properly belongs to it, rather than sequestering it in an inaccessible site from which it will subject us, requires all of these resources.

As the coruscating conclusion to **QUENTIN MEILLASSOUX**'s contribution reminds us, it is not a question of 'full communication', which on the contrary represents a kind of extinction instinctively repugnant to the philosopher, personified in the conceptual incontinence of the

[19] *A Thousand Plateaus*, 461.

'ideas men'.[20] Against all 'anarcho-delirious' worship of flux, Meillassoux reads Deleuze as a Bergsonian philosopher of *subtraction*.

The symphonic sweep of Meillassoux's text – from the *scherzo* of the opening conceit, which introduces an 'unknown Deleuze' in the guise of an obscure pre-Socratic, to the thunderous challenge with which it closes – is an index of the mercurial tenor of Deleuze's own work. Meillassoux's methodological proposal that we approach Deleuze through a mere fragment in order to 'reconstruct' his thought is not at all facetious: Better a modest, even reductive, model culled from a Deleuzian fragment, but understood 'from the inside' – through (re)construction rather than exegesis,[21] than an opaque interpretative quagmire where partially-understood terms become precious tokens too profound to be understood – much less rationally reconstructed – by the profane. But in fact, Meillassoux meticulously demonstrates how the quest for immanence, the theme of 'selection', the refusal of the reactive, and the logic of matter, are all comprised, concentrated, in the tiny fragment, a prismatic shard in which is revealed a distinct-obscure image of the whole of Deleuze's thought.

Pursuing Deleuzian immanence through Bergson's critique of Kant and his theory of pure perception, we meet again with Villani and Alliez and Bonne's analyses, in so far as the thing-in-itself is also a 'telephone to the beyond': a true metaphysics opposes Kantian critique with an affirmation that everything is before us just as it appears, owing nothing to a synthesizing subject. But this immanence raises new problems: why is the 'burl of being' differentiated at all, what kind of interruption of matter is a living being? As Meillassoux demonstrates, pure immanence and individuation can only be reconciled by thinking the body as the locus of a drastic subtraction from the infinitude of matter, a primary selection that provides the terms for the selection of will. This double selection is a key notion in Meillassoux's thought, and here as elsewhere it informs a logic of the event as non-probabilisable and non-deterministic hazard. Events are the movements of 'atoms of void' across lines of flux, but, in line with Deleuze's upholding of Leibnizian continuism, rather than a cut in the fabric of being, here the void is revealed as a stitch in time, a virtual loop drawn out from the weft of the actual.

Haswell & Hecker's performances of work created using composer Iannis Xenakis's digital UPIC system operate a molecular re-engineering of the body through sound, inducing synaesthaesia and an attunement to the microsonic. In their contribution to our volume they present some of the graphisms which are the basis of these transformational events, and their album of UPIC recordings *Blackest Ever Black*. In creating this new work for the UPIC, a computerised system that directly 'translates' drawings[22] into sound, Haswell and Hecker invite a renewal of Xenakis's musical thinking. As discussed in our accompanying text, within Xenakis's own *oeuvre* the UPIC allowed the application to the microphonic texturology of his *concrète* works the same analytical resources his orchestral works had brought to bear on macrocompositional problems. But the invention of the UPIC was also inspired by a will to induct a new generation into abstract spaces of sound which went beyond the confines of musical tradition.

---

[22] Among the drawings used is one representing the microscopic structure of a new material developed by scientists as an optimally non-reflective black surface – hence the title *Blackest Ever Black*. (See http://www.newscientist.com/article/dn3356.html).

Haswell and Hecker's work demonstrates that it would be wrong to reduce Xenakis's marshalling of synaesthesia to a wish to get 'through' the music, to step 'outside-time'. Although he will often seem to view the human ear as a lamentable constraint, a symptom of being a '"Two-faced" mortal',[23] Xenakis, like Deleuze, is ultimately a chronicler of our amphibious condition: the 'outside-time' structures he seeks are always subject to the vagaries of perception, and although our unconscious may be roamed by packs of molecular sound, sonic events are unavoidably always the product of an integration.[24] As in Deleuze, virtual and actual are not the object of a value-laden dualism, but are the inextricable conditions for the emergence of a real: without both of them, no music.

As well as clear Leibnizian-Deleuzian themes (sustained and stable tones as exceptional cases of glissandi; *petites-perceptions*;[25] infinities within infinities[26]), thinking through Xenakis also returns us to a theme that recurs throughout this volume: that of the 'contraction' of quantitative material phenomena into qualities. For Bergson, in liminal phenomena (*e.g.* the lower notes of the scale)[27] a 'detension'[28] comes into operation whereby we begin to break through the operation of contraction-memory and perceive matter itself, perceive the quantifiable series of intensities that science describes. Xenakis investigated this in the form of 'acoustic beats', where the interference patterns of waveforms create rhythmic pulses.[29] These phenomena reveal a continuum between tone and rhythm, a continuum suppressed by the stave's perpendicular separation of infrasonic statistical aggregates (notes) and macrotemporal arrangements (rhythmic placement). In rendering this same stratification transparent,[30] the UPIC engineers a 'transcendental encounter' with the selection we make from matter.[31] The time of music is a biological artefact, a two-dimensional sandbox made by 'folding' the vibratory continuum along a seam constituted by the limits of our auditory system ('Our brain does a kind of statistical analysis', 'Our ear is nothing but a periodicity-counter');[32] a crease in our relation to the physical vibratory continuum. In mimicking these foldings the UPIC gives us the means to probe them, to 'take the reverse path'[33] and to reinsert ourselves into the concrete continuum of sound, outside the traditional strictures of music, with its double-selection of preconstituted 'notes' and metric combinatorial space.

Contraction is thereby revealed as a property, not of a synthesizing subject, but of the folds of matter – revealing to us the 'concrete scale of temporalities'[34] along with our own temporality or rhythm.

We do not truly know how the twenty-one year old student **Gilles Deleuze** came to write the introduction to a republication, by a private press specializing in esoteric works, of Johann Malfatti de Montereggio's nineteenth-century esoteric work *Mathesis: Or Studies on the Anarchy and Hierarchy of Knowledge*.[35] During his early years (1944-8) at the Sorbonne, Deleuze participated in monthly salons organised by the wealthy banker Marcel Moré, a friend of Bataille's. In the leftist Catholic context of the soirées at Moré's apartment and the so-called *sessions de la Fortelle* hosted in mediaevalist Marie Madeleine Davy's grand *château* as 'cover' for Resistance activities, discussions of esoteric topics undoubtedly played a part in what must have been a heady atmosphere, mingling extra-academic intellectual exploration with furtive, morally-charged acts of resistance. Young lights of the Parisian intellectual scene including Deleuze and his close friend Michel Tournier were also, no doubt, respectful of mystically-inclined hostess Davy,[36] whose work suggested that the truth of mediaeval philosophy was to be discovered in a closely-guarded, esoteric, monastic thought that had remained faithful to the mystery of divine revelation.

---

[34] *Ibid.*, 80.

[35] We are endebted to Knox Peden, Thomas Duzer, David Reggio and Christian Kerslake for valuable information and discussion on Deleuze's text which has informed the following notes.

[36] See F. Dosse *Gilles Deleuze et Félix Guattari: Biographie croisée* (Paris: La Découverte, 2007), 116; and J. Moncelon, *Marie Madeleine Davy ou le désert intérieur* (Paris: Les Cahiers d'Orient et d'Occident, 2006). Deleuze prefaces another of the early essays, 'From Christ to the Bourgeoisie' with a dedication to Davy, who also edited a series of books for Griffon d'Or, the publisher of *Mathesis* (see C. Kerslake, 'The Hermaphrodite and the Somnambulist: Deleuze and Jean Malfatti de Montereggio and

But if it was through the patronage of Moré and Davy that Deleuze came to write the piece, this reveals little about his motivation in doing so, nor why he later requested its excision from his official bibliography. In any case, within this essay Deleuze is already operating a characteristic philosophical ventriloquism: To a large extent his reading of Malfatti is an opportunity to articulate his own preoccupations, themes which traverse all of his works of the 1940s. The real question is what Deleuze found in Malfatti that could be affined to his own project.[37] It seems that ultimately Deleuze sees in mathesis a kind of ethical

---

Occultism' in Culture Machine (2007), at http://culturemachine.tees.ac.uk/Cmach/Backissues/j008/InterZone/kerslake.htm, n. 2).

[37] This is not to deny that Deleuze was interested in Malfatti's book, for certain key images present in Malfatti recur throughout later works – see Christian Kerslake's work ('The Hermaphrodite and the Somnambulist – *op.cit.* – and *Deleuze and the Unconscious*, London: Continuum, 2007, particularly Chapter 4), which suggests deeper connections between Deleuze and 'occult' thought, constructing a kind of counter-history to the official account of Deleuze's work by indicating a porous boundary between the canon and 'discredited' occult works. The methodological key to Kerslake's approach might be found in his argument that insisting on the 'obnoxious term "occultism"' itself represents a kind of implacable resistance to the all forms of priestly tradition – even esoteric tradition – in favour of an anti-establishment dedication to all that is obscure and repressed (Kerslake, 'The Hermaphrodite', n. 27). In that case, if it seems immoderate to us to undertake a wholesale reinterpretation of Deleuze's work on this basis, this apparent immoderacy itself answers to the performative exigency of an 'occultist' revolutionary stratagem. Kerslake's renewal of the link between the problem of resistance and the mysteries of the occult is pursued within an irreproachable scholarly framework, which perhaps only augments its seditious potential, even if in the short term it courts the risk of encouraging an interpretation of Deleuze as 'mystic'. What must ultimately be sought is a key to Deleuze's integration of these 'occult' elements, along with the 'official' history and practice of modern European philosophy, into one singular mode of thought. Kerslake's work is invaluable and pioneering in its painstaking recovery of long-forgotten resources that may be necessary for this task, and demonstrates, once again, just how many 'Unknown Deleuzes' there are.

imperative indexed to the refusal of transcendence, and a monism elaborated on the basis of lived experience. As always, then, in the background, it is Spinoza who silently presides over the work in progress.

Deleuze's philosophical voice emerges during a period where the rallying-cry of a philosophy which was to sweep away the severity of interwar *epistemologie* was that of a 'return to the concrete'.[38] The moral disquiet aroused by the dark years of Occupation seemed to demand an unmediated examination of the moral and philosophical stakes of lived experience. For Sartre and his contemporaries an appropriation of Heidegger's work offered a powerful and convenient way to recuse the already-palling academic Brunschvicgian credo that the only way to rigorous philosophical questioning was through an apprenticeship in scientific thought: Instead, it opened up a much-needed *immediate* philosophical access to the politically-dramatic problem of freedom.

Nevertheless, Deleuze does not appear to have taken the easy path of simply neglecting or dismissing science on account of the monstrous engines of death it had recently produced. He does identify the need for the return to 'concrete life' as being an exigency posed at root by 'the principle of an anarchy',[39] that of the apparent irreconcilability of science and philosophy. But, far from seeking to collapse the entire field onto either of these mutually incomprehending discourses, Deleuze describes both as being based upon an uninterrogated ground: that of objectivity (science) and that of the representations of a cognizing subject (philosophy). This dualism, of course, is 'essentially the Cartesian opposition between extended substance and thinking substance'. However, in his aspiration to a *mathesis universalis*, Descartes himself envisions 'a third order, irreducible to the other two […] the unity, the hierarchy beyond all anarchic duality'.[40] Similarly, runs Deleuze's argument, Malfatti's book set out to rediscover this *mathesis universalis* in which (in ancient Indian civilisation) mathematics and metaphysics had enjoyed an original unity, and so to restore us to this unified plane.[41]

---

[38] David Reggio explores this aspect of Deleuze's work in 'Jean Malfatti de Montereggio: A Brief Introduction', at http://www.goldsmiths.ac.uk/history/news-events/malfatti.php; and 'The Deleuzian Legacy', *History of the Human Sciences* 20:1 (2007), 145-60.

[39] Deleuze, 'Mathesis', present volume, 142.

This notion that the knowledge handed down by our intellectual forefathers was subtended by a mysterious lore was indeed widespread into the nineteenth century, frequently paired with that of a unified science or *mathesis universalis*. In the 1946 edition of *Mathesis*, Ostrowski mentions fellow nineteenth-century thinkers Oken and Ampère as seeking the same 'universal synthesis' as Malfatti, and repeats Malfatti's own claims that this mathesis is descended from Plato and Proclus. Descartes, in outlining (in the *Regulae* and the *Géometrie*) his model for a universal science of discovery, similarly confides that he seeks only to *re*discover a hidden science which, going beyond the purely formal and deductive methods available to mathematics in his own day, would explain how the ancients were able to achieve such prodigious feats of discovery.[42]

---

[40] Deleuze, 'Mathesis', present volume, 143.

[41] 'Incognitum' (present volume 156-75) examines the first, numerological or arithmosophical study; For an account of the content of Malfatti's *Mathesis* in its anatomical, embryological and medicinal aspects, see C. Kerslake, 'The Hermaphrodite'.

Deleuze superposes Malfatti's vision of *mathesis universalis* onto that of Descartes; but he also 'twists' Descartes himself. For Deleuze's understanding of mathesis as a third type of knowledge misunderstood by both science and philosophy owes less to Descartes's vision of an *ars inveniendi* that to the 'three kinds of primitive notions' invoked in the correspondence with Elizabeth,[43] where Descartes's response, when pressed on the nature of the union of mind and body, is that although following the thread of philosophical meditation leads us ineluctably to conclude the truth of dualism, in our pre-philosophical state, and in the greater part of our lives where philosophical meditation is pushed aside by everyday life, the reality of this union is quite present *to the senses*,[44] so that the common man perceives no dualism, but a perfect unity. The truth of dualism and the fact of union cannot be present together – we come to appreciate both points of view, suggests Descartes, only in alternating between long periods of unreflective life where union is known experientially 'by means of ordinary life and conversation',[45] and short bursts of meditation. In his 1972 edition of Descartes's *Oeuvres philosophiques*, Alquié will explicitly link Descartes's third mode of knowledge to 'what we call the pre-reflexive',[46] rendering pithily Descartes's contention thus: 'to be conceived of, the union must be lived' [*'pour concevoir l'union, il faut le vivre*'].[47] From the point of view of a philosophy of the mind and a science of pure extension, the union is contingent. And yet it is 'proved' by experience, before philosophical reflection even begins, and again when it ends.[48]

---

[42] See M. Otte & M. Panza. *Analysis and Synthesis in Mathematics: History and Philosophy*, *Boston Studies in the Philosophy of Science* 196 (Boston: Kluwer, 1997). For an account of the importance of *mathesis universalis* in Descartes' mathematical thought, including a history of the notion itself, see C. Sasaki, *Descartes's Mathematical Thought*, *Boston Studies in the Philosophy of Science* 237. (Dordrecht: Kluwer, 2003). Importantly, according to Descartes a part of this *mathesis universalis* lies in the determination of the conditions of a problem (See *Regulae* Book II 'Concerning Problems') – and here, indeed, for Deleuze too one rediscovers the unity of science and philosophy: 'It is in this manner, it seems to me, that philosophy might be considered a science: the science of determining the conditions of a problem' (Deleuze, *Responses*, present volume, 41). However, as Deleuze remarks, Descartes's achievements here belong to the mathematical *stricto sensu*; he failed to apply his discoveries about the constitution of problems to the philosophical sphere ('Descartes the geometer goes further than Descartes the philosopher' – *Difference and Repetition* 323n. 21). Of course, it would be Bergson who would remedy this failure; but all too *philosophically*, so that Deleuze would need to re-inject a differential mathematics into the Bergsonian account of problems, via Riemann, Lautman *et al*…

[43] In particular, Descartes's letter of 28 June 1643: R. Descartes *Oeuvres Philosophiques*, ed. F. Alquié (Paris: Garnier, 1973, 3 Vols) Vol III. 43-4 (R. Descartes *Philosophical Writings*, trans., ed. E. Anscombe & P.T.Geach, London: Thomas Nelson, 1970, 279).

This torsion exerted on Descartes allows Deleuze – at the price of the relation to Malfatti's text becoming somewhat strained – to connect the problematic of *mathesis universalis* to the existentialist 'return to the concrete'. Attaining mathesis will not be a question of lost lore and mystical initiation, but of a transformative thinking of one's own individual existence and its relation to one's fellows, and to the universal.

Sartre was the foremost contemporary influence on Deleuze's philosophical thought. But if Deleuze's contemporaries whispered of him as a 'new Sartre'[49] it was more for his startling creative freedom of thought than for his fidelity to the *maître*'s word. In his early works, Deleuze takes up certain Sartrean themes only to critique and transform them, always on the basis of the argument inherited from *The Transcendence of the Ego* – one of Deleuze's earliest and most abiding philosophical influences – for a field of immanence pre-existing the subject.

---

[44] *Ibid.*, 44 (279).

[48] *Ibid.,* 47n1.

In 'Mathesis' Deleuze takes up Sartre's critique, in *Being and Nothingness*, of Heidegger's notion of the 'crew' [*Mannschaft*] as model for thinking others [*l'autrui*].[50] For Heidegger, the other is no object; rather *Mitsein* is part of the very structure of *Dasein*, as a sort of primary 'ontological solidarity'. Sartre complains that Heidegger has only *described* the problem of others rather than *solving* it, and that his common existence, the primacy of the 'us', tends to level all distinctions, making of each individual a mere case of a generality. But Deleuze in turn felt that Sartre's model of a 'reciprocity of consciousnesses', each using their intentions and desires to paper over the crack in the world which is the other, also evaded the real problem of others: it imagines pure consciousnesses stealing the world from each other, undermining each others' centralisation, with the world being merely the empty field across which their combat rages. Sartre's progress over Heidegger lies in the fact that he recognizes the relational aspects of the subject to the other; but his error is to make the other its own *I*, an inverted image of myself.[51]

---

[49] Dosse, 116.

[51] See A. Beaulieu, *Gilles Deleuze et la phenomenology* (Paris: Sils Maria, 2004), 61-3.

In another 1946 paper, 'Description of a Woman', Deleuze condemns Sartre's conception of love, which, he argues, seems to be predicated upon a sexless and neutral world of 'pure souls', so that sexuality is conferred upon the beloved only by the lover. In moving toward the definition of an immanent, *a priori* structure of the other – and therefore a conception of desire without lack – Deleuze announces the 'great principle'[52] of his early work: 'Things haven't been hanging around waiting for me in order to exist'.[53] For 'I do not attach my little significations to things. The object does not *have* a signification, it *is* its signification.'[54] The world is already a world of *concepts*, of things bonded with significations, before the subject even appears.[55] In concrete, pre-reflexive experience, it is not that 'I am tired', but that there is a 'tired world' in which the road, the sun, are all tired.[56] Equally, there is not an objective cube and the space which we impose upon it as form of appearance, nor even a fullness hollowed-out 'behind' our adumbrations of it, but the cube as concept.[57] Into this immanent world comes the other, as possibility of *another* world, and at once I become I, that is, I decompose these concepts, making part of them 'mine' and part the objective world's. Where before there was a world of concepts 'in the flesh', or 'phosphorescent objects',[58] now there is 'my world', a world that immediately appears 'mediocre'.[59] Expelled by the 'intimate phosphorescence' of pure immanence, each individual qua individual must face the other-as-possible-world in 'mediocrity', without any common measure, each taking on the problem of life on their own account: how is the universality of life to be thought, regained?[60]

[55] Hence 'concepts are the things themselves, but things in their free and wild state, beyond "anthropological predicates".' (*Difference and Repetition* xx-xxi, translation modified).

[56] Deleuze, 'Description of a Woman', 17-8.

[57] Deleuze, 'Mathesis', present volume, 148-9.

The immediate political stakes of 'Mathesis', where this convoluted philosophical argumentation rejoins the urgent contemporary affirmation of the concrete, are made plain in Deleuze's citation of Ostrowski's preface.[61] The 'human problem', a practical problem which mathesis aims to solve, is that of the betrayal or affirmation of 'complicity'. Where Nazism, 'a unity founded on a cult of force', assembled its crew on the basis of a subjection to general principles and a biopolitical substitutability, we must found a conscious complicity on the basis of an initiatory experience of the universality of life, guided by the principles of mathesis. The 'human problem'[62] lies not in creating a crew whose members would be 'equal' and interchangeable, but in 'passing from a state of latent ignorant complicity to an affirmative complicity', affirming that 'the universality of life as an outside' is attested to in each apparently isolated individual, and indeed genetically conditions and constitutes him.[63] Far from mathesis being a transcendent mysticism, then, for Deleuze it describes a discourse on the condition of *a life*, relating it to the infinity of Life; a logic of 'the multiplicity of living beings which knows itself as such' and 'refers back to unity' through 'complicity'.

---

[58] All of this is developed most beautifully in Michel Tournier's novel *Friday* (trans. N. Denny, NY: Pantheon, 1985), a book that is absolutely crucial for understanding of the early Deleuze – It is clear that in the Sorbonne years, in advance of the 'rhizome Deleuze-Guattari', there was a 'rhizome Deleuze-Tournier'. In Tournier's novel, Robinson is disabused of the conception of the subject in the world as a 'spotlight' passing over various indifferent objects with its attention and intentions, realising that it is modelled upon the thought of *another* as a secondary structure of selection within a world that *must already be constituted* in order for that selection to take place. This first world, one of 'objects phosphorescent in themselves', is ruptured by some singular anomaly or inconsistency, and 'excretes' the subject. In 'Tournier and the World Without Others' (*Logic of Sense*, 341-59), Deleuze will explicitly name this a structuralist theory of the other (the other is a structure which particular others can come to occupy); but the importance of *Friday* lies in its demonstration that the 'structure' is neither ontological nor eternal – in certain circumstances it is liable to decompose, returning the world to its phosphorescent state through a series of intermediate disintegrations – from Robinson on the isle of Speranza to Robinson-Speranza. Tournier-Deleuze participate at once in the structuralist destitution of existentialism and in a virtual flattening of structure into a field of immanence – however knotted, the thread that binds us can always be unravelled and followed back to this virtual field.

[59] See Deleuze, 'Statements and Profiles', 86-7: in this 1946 essay the 'crew' represents the possibility of reconciliation with the otherwise threatening and hostile 'alternative possible world' of the other: I 'team up with the other' to realize a world beyond what has now become 'my world' and thus mediocre. Although the threat of rivalry still subsists within 'the spirit of the crew', 'The Crew is the only way to escape from mediocrity'. *i.e.* from the contingency that appears as soon as one 'owns' the world as a subject. Meanwhile the task of philosophy is that of 'remov[ing] any pejorative sense from the word mediocrity'.

[60] Deleuze, 'Mathesis', present volume, 144.

1953's *Empiricism and Subjectivity* seems a valuable 'missing link' between 'Mathesis' and *Difference and Repetition*, in that it marks the first appearance of a quasi-mathematical concept of integration in precisely the same context – the creation of the social in a model that refuses forced sociality in favour of the *positive realisation of complicity* ('The question is no longer about transcendence, but rather about integration';

---

[61] *Ibid.*, 145-6.

[62] *Ibid.*

[63] *Ibid.*

'The problem of society […] is not a problem of limitation, but rather a problem of integration […] to integrate sympathies' writes Deleuze, building on the thesis of the positivity of institutions outlined in 'Instincts and Institutions').[64] This in turn may point the way towards Deleuze's ultimate model of *mathesis universalis* in *Difference and Repetition*, that based upon differential calculus. If that work turns to mathematics *simpliciter*, this would seemingly tip the balance of the 'anarchy' in favour of science; but equally there seems to be a reciprocal movement whereby Deleuze 'esotericises' that very mathematics, by approaching it through routes he calls 'barbaric' and even explicitly 'esoteric'.[65]

In the 1946 essay, mathesis is neither mathematical nor mystical. Like Bergson's intuition, it relates to the individual's solitary path, once displaced from 'a world' to 'my world', towards a rediscovery of the immanence of the concrete and immediate – a way to recover from a 'fundamental lapse of memory' on the part of Being itself[66] through an understanding of the meaning of individuation (the 'natal'[67] rather than being-towards-death). Mathesis treats of the nature of life anterior to philosophical reflection and scientific objectivity, that is to say before the cleavage between the subject and object of thought: it returns us to 'things-in-themselves in their wild state', the world of *concepts fauves*.

---

[64] In *Desert Islands*,19-21.

[65] *Difference and Repetition*, 170. Deleuze's other 'occult' influence, the Polish messianist Hoëne Wronski, was also a mathematician, and defined a quite properly mathematical 'supreme law' which, unifying all mathematical functions and thus all scientific knowledge, was to provide the only possible opening to a true *mathesis universalis*. For a general account see P. d'Arcy, Hoëné-Wronski, une philosophie de la création (Paris, 1970); For a mathematical exposition see C. Phili, 'La loi supréme de Hoëné Wronski: La rencontre de la philosophie et des mathématiques', in E. Ausejo, & M. Hormigón (eds) *Paradigms and Mathematics* (Madrid: Siglo XXI de España Editores, 1996). More important to Deleuze, however, is Wronski's defence of a true (non-finitistic) mathematics of the infinitesimal (See A. Guerraggio & M.Panza, 'Le Réflexions di Carnot e le Contre-Réflexions di Wronski sul calculo infinitesimale' in *Epistemologia* 8:1, 1985:3-32). For it is on this point that Deleuze will take his stand against the divergence of mathematics from philosophy, in advocating a return to 'barbaric' or 'esoteric' interpretations of the calculus.

[66] 'Bergson, 1859-1941', in *Desert Islands and Other Texts*, 23.

In *Le désir de l'éternité*,[68] Alquié had founded human experience on an essential loss and nostalgia attendant upon our finitude, allowing as true philosophers only those who had the courage *not* to claim vainly to reestablish links with the infinite and the immortal (Spinoza, therefore, the ultimate enemy). Why, then, does Deleuze aver that he learnt the specificity of philosophy from Alquié?[69] Perhaps because he affirms Alquié's conception of philosophy as being linked with a fundamental encounter, whilst refusing the proposition that in this initiatory moment we meet the *inadequacy* of our finite thought: for Deleuze, to authentically encounter our 'mediocrity' or 'enfoldedness' is at the same time to discover the thread that can guide us back to infinite immanence: When we truly encounter that which can only be experienced from the point of view of our individuation, we also encounter a phosphorescent outside that no longer receives its status from elsewhere, and that is our true 'common measure'.[70] This, finally, is the meaning of

[69] 'The Method of Dramatization', in *Desert Islands*, 107.

[70] Since Deleuze's Malfatti not only reverses the cogito – ('sum, ergo cogito') but also introducing sexuation and reproduction into it ('sum, ergo genero') – this text evidently belongs to the period when 'there was still a specifiable relation between sexuality and metaphysics' (Deleuze, 'Questions', present volume, 40). The notion of the sexual act as the highest point of pre-reflexive existence, when the individual,

mathesis for Deleuze; all that is 'mystical' about it is that each must live it on their own account – in Alquié's words, *pour concevoir l'union, il faut le vivre*. We must initiate ourselves into the immanence of conscious complicity[71] – not, like Descartes, 'by means of ordinary life and conversation', but perhaps like Bergson, through a concentrated effort to reach 'the immediate data', guided by symbols-concepts.

It is a paradox that a philosopher who spoke out in the strongest terms against the history of philosophy as an oppressive institution[72] should demand, for a full understanding of their work, a formidable labour, precisely, in the history of philosophy – and not even just in philosophy, since from the start Deleuze drew upon eclectic resources. A difficulty facing the would-be student of Deleuze's works is that, considering this breadth along with the complicated conceptual modulations to which he subjects his sources, Deleuze seems simultaneously to demand and to repel close scholarly scrutiny. **John Sellars**, however, has had the courage to begin this work, specifically in exploring Deleuze's (and Deleuze/Guattari's) use of ancient

---

the species, and nature itself are affirmed at once, is obliquely taken up in 1953's 'Instincts and Institutions' where the question of reflex, 'at the intersection of a double causality' leads to the question 'Useful for whom'? – See 'Instincts and Institutions', in *Desert Islands*, 20-1.

[71] Marie Madeleine Davy dedicated much study to the concept of 'initiation' (Moncelon, 5). Other echoes of Davy's doctrine of a 'pure experience of the presence of the divine which cannot be transmitted' (Moncelon, 3) can be found in Deleuze's work. For Davy, 'The liberatory awakening is achieved in the desert, *i.e.* in the country of thirst, of the reading of signs and of the encounter. The true encounter takes place within, and becomes experience. An inexpressible experience whose essence is unknowable' (*Ibid.*, 2). For a less apophatic but undoubtedly related understanding of the 'inner desert' as initiation in Deleuze, see 'The Shame and the Glory: T.E.Lawrence' in *Essays Critical and Clinical*, 115-25.

[72] See *Dialogues II*, 13.

sources. In thus calling Deleuze's bluff, he makes possible an intriguing glance behind the scenes, of a type that no amount of enthusiastic intra-Deleuzianism could yield.

In order to determine what transformations Deleuze exerts upon the supposedly Stoic theory of time advocated in *Logic of Sense*, Sellars compares Deleuze's exposition against that of the Stoic thinkers themselves. Now, Deleuze certainly never concealed the fact that he approached other philosophers, not with a view to representing them faithfully, but with a view to producing new 'monsters'. Accordingly, whatever cautions it may suggest to us regarding our reading of Deleuze, Sellars's article should not be read as a debunking 'exposé'. Rather, like Meillassoux's demonstration of the 'grafting' of Bergsonian onto Nietzschean selection, it exemplifies a 'stratigraphic' superposition in the 'ideal space' which, according to Deleuze, is characteristic of philosophy.[73] Explicitly-held doctrines are traced back into the problematics that spawned them, introducing a depth of field into the linear view of the history of philosophy. If, in the process, positions become attached to the 'wrong' names, it might well be said that this reveals the real, effective, process of doing philosophy: creative moments only arise out of such slippages and misalignments. That said, as a case study in Deleuze's 'ventriloquism' in the history of philosophy, Sellars's is certainly a cautionary tale: in the absence of research such as this, mere recitals or applications of theories such as 'the stoic theory of *Aiôn* and *Chronos*' will conspire against any possible estimation of the extent and nature of Deleuze's philosophical inventiveness.

---

[73] *Dialogues II*, 16.

If Meillassoux proposed that we make the text 'not the *object*, but the *instrument* of the elucidation' of Deleuze's work,[74] **Mehrdad Iravanian**'s is an even more radical methodological proposal. Perhaps, in addition to drawing on his architectural practice, recalling the Islamic tradition according to which any 'text' that can be systematically extracted from the Koran belongs equally to the word of God,[75] Iravanian offers a development of Deleuze's thought in *The Fold* that owes absolutely nothing to external interpretative resources, but seeks an 'unknown Deleuze' through an approach at once graphic and truly 'literal', dealing with 'unread characters'.[76] This explication of Deleuze's book employs the text both as methodological programme and raw material for a transversal experiment in architectural ontology and impersonal memory.

Thomas Duzer's text 'In Memoriam' of Deleuze offers a concentrated survey passing through the major themes of our volume, and indeed of Deleuze's *oeuvre*, working backwards from the philosopher's dramatic exit from our world, over a decade ago now. In particular, Duzer sets out vigorously to defend Deleuze against Badiou's *post-mortem* critique, quite correctly refusing to cede to the conception of Deleuze as 'virtuoso phenomenologist'.

We have already mentioned the diversity of sources Deleuze drew upon in assembling his singular philosophy. In particular, the eclectic table of references in *Difference and Repetition* has only just begun to be mined for insights into the development of his thought. **J.-H. ROSNY**'s enchantingly weird SF tale 'Another World' sheds some light on one of the now-obscure authors cited therein.

[76] Iravanian, present volume, 232.

Rosny discovers two necessary tendencies at work in life and in thought, corresponding to the 'two deaths' unveiled by Meillassoux,[77] or to *Anti-Oedipus*'s two poles of paranoia ('a growing simplification […] more and more abstract negative concepts […] pseudo-void')[78] and schizophrenia ('the mind is lost in the infinity of forms and actions').[79] We might draw a parallel also between Rosny's faith in scientific thought and the instinct for beauty, and Xenakis's affirmation that universality is achieved 'not through emotions or tradition, but through the sciences,' guided by the artist's intuition.[80] Duzer characterizes the Deleuzian break from truth-as-master-category as consisting precisely in such *experimentation*,[81] and Rosny, as will be seen in this tale, was the champion, above all, of experimentation.

In trying to identify the philosophical specificity of Deleuze, one name arises most often. It seems as if, in order to give Deleuze the proper philosophical status he deserves, the same must be done for Bergson, who – at least in the Anglo-American philosophical community – languishes on the sidelines, still apparently harbouring 'something that cannot be assimilated' to 'an image of thought called philosophy.'[82] Along with Deleuze's attempts, already in his early works, to recreate a true ('phosphorescent') Bergsonianism *against* the contemporary heralding of phenomenology as the arrival of a true (that is, corrected) Bergsonianism, we should mark Meillassoux's identification of a *differential* between Bergson and Deleuze: What is important in the relation Bergson-Deleuze is their *divergence*, what Deleuze *selects* from Bergson. And the extent to which, in making his selection, he sets out to become 'more Bergsonian than Bergson'. One could say this also of the other philosophers Deleuze encounters – is he not also 'more Kantian than Kant' in his pursuit of a transcendental philosophy and an immanent critique beyond the inherited philosophical categories which Kant desperately tried to re-erect within them? 'More Sartrean than Sartre' in selecting the pre-reflexive immanence of *The Transcendence of the Ego* as the master's singular moment, and setting out to preserve and prolong it? A supreme 'Leibnizian' in preserving the monadological *mathesis* but affirming the primacy of divergent series …? Every philosopher is the site of warring endeavours; Deleuze extracts what he considers the most powerful, the most revolutionary lines, and extends them as far as they will go (for example, in his 'selective reading' of *chronos* and *aiôn*). We certainly need, for example, a *critical* examination of Bergson, with an eye to what is irretrievably obsolete in his thought – but, as Meillassoux shows, Deleuze himself already carries out this operation: and in fact the shaping of Deleuze's philosophical assemblage often occurs when lines of argument selected from one influence limit those from another.[83]

[83] We have seen above that the rethinking of *l'autrui* was a founding moment in Deleuze's formation, as the 'possible worlds' of Leibnizian perspectivism cut across Sartre's oppositional model. We would also indicate the important critique

Of course, we should not be afraid to do the same with Deleuze himself; to read him selectively would indeed be an apt task for a post-Deleuzian era. But in order to get to the stage where we can do so, we have to understand – or even better, reconstruct – the various dimensions of Deleuze's philosophical thought, paying attention to their interrelations and interdependencies. Another 'differential' appears to be key to this task: Thomas Duzer's article confirms that an examination of Deleuze's work would today be unthinkable without reference to Alain Badiou's *The Clamor of Being*. And the service Badiou's remarkable and provocative book has done to Deleuze consists in making it impossible for 'Deleuzianism' to remain a comfortable orthodoxy sheltered from all criticism and unprepared to define and defend its key concepts rigorously. There can be no doubt that the controversy – at once ontological, political and aesthetic – between Badiou's still-evolving work and the legacy of Deleuze's, will be an enduring one. But what counts is to ensure that it serves to deepen our appreciation of the complexity of the work of both thinkers, rather than betraying it through mutual caricature and partisanship. This means preserving the chances, not of a reconciliation, but of a fruitful confrontation.[84]

---

of Bergson's critique of intensity (*Difference and Repetition* 239), on the basis of the Nietzschean requisites for a theory of force (See *Nietzsche and Philosophy*, 27 – Bergson's mistake was precisely to have 'invoked the rights of quality', confusing quality with the intensive and attributing to the former what belongs properly to the latter). The relevance to Alliez and Bonne's reading of Matisse should be obvious.

[84] Note that both Villani – a key protagonist in the initial, hostile reaction to Badiou's book in French Deleuzian circles – and Meillassoux – a former pupil of Badiou's (although by no means a 'disciple', since he has clearly defined an original philosophical project of his own) both end up, along with Badiou (but in very different ways) defining Deleuze's primary philosophical orientation as *ascetic*, whether (for Meillassoux) 'subtractive', or (for Villani) 'drastical'.

So what indeed, for instance, 'made [Deleuze] choose the word "life" as Being's main theme'? This is, as Badiou says, 'a real question'.[85] But here as elsewhere, the *bons mots* that have entered into circulation as convenient slogans for 'summing up' Deleuze have served his philosophy badly. '[N]ever write a single sentence which is not immediately a vitalist affirmation' – rather than abusing this as a confirmation for whatever tendency we have decided in advance to advocate or denigrate in Deleuze, it must be subjected to the kind of close scrutiny exemplified by the contributions to this volume.

We wager that as this is done, it will become evident that Deleuze's vitalism, rather than being a simple 'given', constitutes a central *problem* in his work. As Duzer hints, even in his death Deleuze morally distanced himself from a vitalism that would uphold the sanctity of life at all costs. The 'life' Deleuze speaks of is expressed in stranger, more hidden varieties: it has as much, if not more, in common with the 'life of music'[86] whose forms Xenakis dissected; the life of colour as explored in Matisse-thought[87] (or, indeed, the 'exemplary life of the soil' of Dubuffet's *texturologies*, or 'one of Pollock's lines');[88] the life of knowledge as evoked in Malfatti's *Mathesis*,[89] or the vitalism-structuralism of Rosny's structures of beauty or his evocation of the 'life of science'[90] – and even (affording a glimpse of one of those common inherited problems of Badiou and Deleuze) the 'life of mathematics' spoken of by Cavaillès and Lautman,[91] than with a vulgarised Bergsonian *élan vital.* Only once we understand the common thread that runs through these 'forms of life' will it be opportune to ask (but perhaps then the question will not seem so simple) whether this 'vitalism' can be salvaged from a philosophically fatal analogy with the biological animal. In short, if Deleuze's thought is a 'Fauvism' then it is one which, like Matisse's, owes nothing to a Romantic conception of expression valorising spontaneity and anarchical liberation.

The contributors to this volume instead describe a life as the outcome of meticulous selections, a barricade against the infinitude of matter which nevertheless maintains a thread back to that infinitude. And a subject which – far from preceding and governing what is perceived, 'belongs wholly to matter'.[92] Given the equal importance for Deleuze of the problems of the withdrawal from flux, of actualization, and of construction, his metaphysics cannot be reduced to a quasi-religious valorization of the virtual. The virtual, the 'dream',[93] will always lack reality, which belongs to the 'inclusive disjunction of the actual and the virtual'[94] and their mutual interplay.[95]

---

[90] 'Just as the syntheses, the orientations, the repetitions of the organism, have not resulted in uniformity (the living being is more and more differentiated), so the syntheses, the orientations, the repetitions of science do not have homogeneity as their outcome.' *Les sciences et le pluralisme*, 7.

[91] It is surprising to see such a phrase in the work of such a reputedly 'severe' philosopher. For Cavaillès, it seems, this mathematical life was nurtured through a series of 'gestures' which transformed previous thoughts into the objects of a new thought, gestures which he set out to describe and classify. (See the 1939 discussion between Lautman and Cavaillès in 'La pensée mathématique', *Bulletin de la Société française de philosophie*, 40 (1939), 1-39; reprinted in Jean Cavaillès *Oeuvres Complètes de Philosophie des Sciences* (Paris:Hermann, 1994), 593-630.

Along with Brunschvicg's 'Mathematical Philosophy', French *epistémologie* was also animated, albeit unavowedly, by the Bergsonian theme of the primacy of the problematic (see E. During '"A History of Problems": Bergson and the French Epistemological Tradition', *Journal of the British Society for Phenomenology*, vol. 35 no. 1, January 2005). More fruitful, therefore, than betraying it by making it the object of an exclusive dialectical choice between philosophers of 'life' and those of 'the concept' (See Badiou, 'The Adventure of French Philosophy', *New Left Review* 35, Sept.-Oct. 2005), would be to explore as a singular formation this vigorous philosophical movement founded on the practice of interrogating science in its becoming rather than as stockpile of knowledge (for such an approach, see Frédéric Worms 'Between Critique and Metaphysics' in *Angelaki* 10:2 (Aug. 2005):39-57).

Yes, Deleuze's thought unfolds within the element of philosophy, it is *a philosophy*[96] in the grandest and most speculative sense: a genetic structuralism, a transcendental empiricism, an abstract vitalism, an ethics as 'knowledge of life and life of knowledge';[97] but above all it develops the logic of multiplicities[98] required to describe – within a pure immanence, infinitely implicated, shaped by problem-ideas or nested series of differences – the constructive-expressive actualisation of a singularity through partial, local cut-outs integrated to make a whole, a new, singular and dynamic point of view, a life.

[92] Meillassoux, present volume, 75.

[93] Villani, present volume, 50.

[94] *Ibid.*, 51.

[95] It seems equally mistaken to think the relation as one of irreversible emanation from virtual to actual, or of spiritual ascent from actual to virtual: Deleuze speaks of 'virtuals' and 'the actual particles by which they are *both emitted and absorbed*' ('The Actual and the Virtual', *Dialogues II*, 112; italics ours; *Cf.* the important concept of 'miraculation' in *Anti-Oedipus*, 12-3.

[96] See Duzer, present volume, 250-1.

[97] Deleuze, 'Mathesis', present volume, 147.

[98] Whilst Badiou tells us simply that 'Deleuze despised logic' (A. Badiou, *Briefings on Existence: A Short Treatise on Transitory Ontology*, trans. N. Madarasz, NY: SUNY Press, 2006, 122). Deleuze displaces it into an empiricist *mathesis universalis*: 'logic does not interest us, either everything is logical or nothing is' ('Capitalism and Schizophrenia' in *Desert Islands*, 2004 *XX*) yet 'empiricism is fundamentally linked to a logic of multiplicities' (*Dialogues II*, 'Preface to English Edition', viii).

We do not claim to have presented in this volume a definitive and complete account, but instead a series of cut-outs, a kind of collage, or a transversal selection of elements, towards an 'all-over' portrait of Gilles Deleuze. As the contributors demonstrate – something that is often missed when theorists seek to make use of one or another of Deleuze's concepts – Deleuze is a philosopher whose thought is at its most powerful when concentrated, grasped as a whole, even if at those rare moments when we manage to do so – when 'all parts have found their definitive relations'[99] – we are all too aware that it will once again escape us. This, after all, is the measure of the complex action of a philosopher's thought, which must therefore be 'creatively limited'[100] in order to be prolonged. We intended to make possible some such moments of concentration, some such creative selections.

We would like to end by expressing our sincere gratitude to all of our contributors, who have given freely of their work and of their time, in what has once again been a truly collaborative process. The assembly of this volume has proved the most challenging yet, but, as we hope to have indicated in this brief survey, in the making it has become far more than the sum of its parts.

Robin Mackay

In Memoriam: Gilles Deleuze (1925-1995)

Thomas Duzer

> Between the intensive and thought, it is always by means of an intensity that thought comes to us.
> (Deleuze, *Difference and Repetition*)

*

> Young man, do not incriminate the gods!
> (Sartre, *The Flies*)

On 4th November 1995, Gilles Deleuze committed suicide by throwing himself from the window of his Paris apartment. He was 70 years old. In 1969, after having completed his major thesis (later published as *Difference and Repetition*), he was rushed to hospital, and diagnosed with tuberculosis; emergency pulmonary surgery immediately followed. With the passing years his health slowly deteriorated, and by the end of his life, he was dependent upon a machine: an artificial respirator.

Obviously, the question of Gilles Deleuze's suicide remains a problem which can quite properly be considered as a part of his philosophy. Indeed, by overstepping

Spinoza's prohibition, he would choose to withdraw from the scene at his own chosen moment. Ultimately it was stoicism that the vitalist philosopher chose, faced with the compounded forces which had appropriated the extensive parts subsumed under his modal essence. But perhaps these are not the best terms in which to pose the question of the ultimate meaning of his philosophy. Didn't Deleuze's thesis director, Maurice de Gandillac, emphasise his student's visceral Nietzscheanism and keen interest in Diogenes Laertius's doxographies? From the moment he began his studies at the Sorbonne, behind each philosophical system Deleuze sought the philosopher as individual: Which body? Which thought? Every philosophy is a vital and affective evaluation, an animal perspective, and a theoretical bringing-into-engagement. Every philosophy is the theory of a practice, or the systematization of an immanent way of living, of *a singularity*: For Deleuze, *every ethics is the correlative of an ontology*. In this, he is absolutely Spinozist.

This is the secret centre of the long and patient years he dedicated to the history of philosophy. In his early monographs, Deleuze does not interrogate a philosophy so much as a philosopher – which explains the strange character of these works. For in reading them, one becomes aware that, although there is no doubt that the Deleuzian commentary concerns the same author treated in classical erudite tradition, a sort of rupture is always in evidence, a sort of *Unheimlichkeit* and a problematisation that is difficult to situate. But this is so only in so far as one attempts to locate the Deleuzian reading within the perspective of a classical history of philosophy, whose logic of exposition is that of a chronological procession of concepts and systems.

For his part, Deleuze preferred to refer to a time that he called 'stratigraphic.'[1] It is certainly important that philosophies succeed one another in time. Nevertheless, these philosophies are *virtually* coexistent. Every philosophy is *virtually* contemporary with every other, even if certain logics creep into those that preceded them, and certain concepts are reclaimed in their original form. Thus, *in the present*, every system of ethics rivals every other, since, *in reality*, all logics are in non-dialectical conflict with each other. More precisely, according to Deleuze, any philosopher worthy of the name – that is to say, any philosopher-creator – traces out a plane within chaos. For concepts are born of thought's confrontation with chaos. Or, in other words: concepts must be *created*. They are dated and signed, even if later philosophers must divert them from their original function, hijacking their components and their flows. This means that every new plane, if it is to inaugurate a truly new philosophy, even if it should have originated from an anterior plane, must distinguish itself from and find its own autonomy from the latter. But how? Most fundamentally, it is through assuming his own problematics – even if these problematics are not explicitly thematized – that the philosopher has a chance of tracing such a plane. And, on this plane, a new consistency may be given to chaos, by means of the singular creation of the arsenal of connected concepts that populate it. For Deleuze, the style *is* the philosopher.

And it is from somewhere close to this *active centre* of Deleuze's philosophy that Badiou's attack seeks to draw its force. With an incisive gesture, Badiou takes Deleuze's *continuous variation*, a major element in his philosophy and his style alike, and annexes it to one of his enemy constellations: *phenomenology*.[2] This judgement may seem reasonable at first, but on further consideration becomes absurd. For Deleuze declares, as a Spinozist, his hostility towards all philosophies of the *Cogito*. Clearly, for him, there is no subject.[3] Every philosophy that concedes any legitimacy to the Ego is anathematised. Even the non-thetic[4] *Cogito* of

---

[1] See *What is Philosophy?* and also the distinction between *Aiôn* and *Chronos* in *Logic of Sense*.

---

[2] A. Badiou, *Deleuze: The Clamor of Being*, trans. L. Burchill. Minneapolis: Minnesota University Press, 1999.

[3] The critique of the Subject has been a *topos* in post-Cartesian philosophy ever since the *Objections to the Metaphysical Meditations*. However, after the Humean episode, it was generalized following Mach and Nietzsche, who, as a matter of fact, later spawned two divergent philosophical tendencies. Similarly, psychoanalysis profoundly modified the notion of the subject through the notion of the unconscious; Heidegger, having broken away from Husserlian phenomenology founded on Kant's inherited and enhanced *Cogito*, replaced the classical and transcendental subject with *Dasein*. The list of subjectivity's detractors in the twentieth century is certainly a long one. Nevertheless, the notion, although drastically modified at times, was never abandoned. But Deleuze affirms in a 1988 interview entitled *Signs and Events* that there is 'no subject [...] there are only processes, sometimes unifying, subjectifying, rationalising, but just processes all the same.' (*Negotiations*, 145). Undeniably, from *Empiricism and Subjectivity* onward, Deleuze asked, through the works of Hume, whether or not subjectivity is constituted within the given, within the 'flux of the sensible'. It seems, in fact, that the critique of subjectivity comprises a guiding thread in Deleuze's *oeuvre*. As a question it certainly intersects with his major problems and concepts, and turns out to be one their conditions of possibility: desire, multiplicity, BwO, 'to be done with judgement,' plane of immanence, and domain of transcendence ... But this critique cannot be reduced to a simple questioning of the subject. Deleuze promotes another type of individuation, a 'non-personal individuation', *haecceities* and singularities. The construction of these concepts intersects and enriches the problematics of other philosophers such as Foucault, Klossowski, Blanchot, or Artaud amongst others. With the help of Guattari, moreover, this construction opposes psychoanalysis in order to substitute a machinic unconscious for a theatrical unconscious. In short: 'there is no longer a subject, but only individuating affective states of an anonymous force.' ('Spinoza and Us,' in *Spinoza: Practical Philosophy*, 128).

[4] For Sartre, consciousness, being spontaneous, is effected within a 'prereflexive *cogito*,' unlike a cognition that implicates the object-subject couple; *conscientia* is not

Sartre, Deleuze's admired *maître*,[5] is rejected. What does this mean? All philosophy that claims to found itself on the central positing of an *Ego* plainly privileges substance over process. Why reject this? Because it is the triumph of reactivity. It is apparent that what makes a rhizome of the postwar Nietzscheans is ultimately a reading of Kant's Copernican revolution as *reactionary* – making the object turn around the subject changes the order, but *not the places*.[6] If the Ego, the World, and God are transcendental illusions of theoretical reason, they remain regulative ideals and, as noumena (objects of thought and not of knowledge), lose none of their force and pertinence in Kant's philosophy, at the heart of practical reason. Whereas, on the contrary, the Nietzschean revolution leads thought into an *a*subjective becoming: a comet-thought, the wandering star whose variations in speed and whose creativity constitute its coherence.

Thus, Badiou describes Deleuze's conceptual creations as virtuoso *phenomenological* apparati. His philosophy, especially when 'machined' with that of Guattari, will be ultimately monotone and repetitive. But this reading of Deleuze *fails*, in the sense that one might say of an encounter that it failed. For as we well know, one must refrain from suggesting some sort of general falsification of Deleuze

---

cum scientia. Such a prereflexive *Cogito* therefore insists on a presence-to-self that is immanent and anterior to the 'return to self' engendered by reflection. Consciousness is 'to be for oneself' and refuses to settle as object: it is non-thetic.

[5] 'He Was my Teacher', in *Desert Islands and Other Texts*, 77-81.

[6] This is a strictly structuralist discovery: the symbolic – implying that in a structure, the position, the place, is primary with regard to that which occupies it. See 'How Do We Recognise Structuralism?' in *Desert Islands*, 170-92.

on Badiou's part.[7] Indeed – and the sly Badiou certainly knows how to remind orthodox Deleuzians of this – for a Nietzschean, the distinction between the true and the false never makes for a strong argument. In fact, Deleuze always favored the problematic of stupidity over that of error – that is to say, that of sense over that of truth. This is a corollary of the destitution of substance in favour of process. One of its consequences is the absolute rejection of a foundational subject or, as we have already seen, of any *Cogito*, whether it be Cartesian or Kantian, or indeed any analytic of *Dasein*. Deleuze's principal weapon against stupidity naturally turns out not to be a Heideggerian anti-humanism – which continues to concede rather too much to its opposite, even if only in order to situate itself, in Hegelian manner – but rather a strict *inhumanism*. At this point, Artaud is convoked as schizophrenic, *i.e.,* practitioner of the theory. For this is exactly what interests Deleuze so deeply about schizophrenia: that intensities are consumed *directly*. Thought articulates itself upon the body as its obverse and reverse. Within this intensive machinism, the 'Theatre of Cruelty' reveals the factories of the unconscious. Presentation is presented in its purity, without the mediation of representation: *incarnation* replaces identification and recognition.[8]

Truth and error, both structures of recognition, are merely the result of the correspondence or non-correspondence of a given case with a rule. On this point it is essential to note that to consider, as Deleuze did, that truth[9] is not an 'interesting' category doesn't indicate that it is refused wholesale, but rather that it is ratified but *not made sacred*.[10] To deny or to affirm a proposition implies that this is done according to truth, and thus according to eternity. Nevertheless, in the 'power of the false', as endorsed by Nietzsche, for example, there is something more than a simple negation of truth. *Anti-dialectically* speaking, affirmation cannot result from the negation of a negation. And this is why the problem of stupidity and consequently, that of the remarkable, the interesting, the singular, and the novel, are *transcendental*. For, following Bergson, it is a question of applying the test of truth and falsity to the problems themselves. Here, not only are the rule itself and its legitimacy interrogated, they are *experimented* with – it becomes necessary to ask not just 'what the principles are, but what they do'.[11] Thus, morality, together with the substantialisms of the Same, is abandoned in order to constitute an ethics, as experimental and processual science. In the wake of William James and American pragmatism, Deleuze proposes a *transcendental empiricism*, which can be expanded into a cartography of intensities conceived as *patchwork*, *computation*, and non-diplomatic immunity.[12] Consequently, if, as Littré says, truth is 'the quality by which things appear as they are,' then we can affirm that a transcendental empiricism is the activity through which beings *become* what they are.[13] It has been possible to paint Deleuze, as does Mattéi,[14] as contemptuous toward the *archê*, the Father, or the Master, but it is the One he adamantly challenges, in favour of a pluralist philosophy (the power of the indefinite article – *an* archê, *a* Father, *a* Master ...) Following Nietzsche's example, then, it is Platonism, but Platonism *qua* inherited philosophy, that he seeks to invert: To reject, not Plato as creator, but Plato as leader of a school, father of the *Diadochi*; to challenge the principle of succession which Plato made possible by positing the created concept as increate Idea. Thus it is not at all a question of indifferentiation, or a nihilist principle of abolition, as Mattéi maintains. Indeed, as Badiou himself recalls, 'contrary to all egalitarian or "communitarian" norms, Deleuze's conception of thought is profoundly aristocratic.'[15] Thus, Deleuze chooses the 'Platonism of encounters'[16] over that of the 'Good beyond Being'.

---

[7] See, for example, the diverse receptions of Badiou's *Deleuze* in the review *Multitudes* (*formerly Futur Antérieur*).

[8] Schizoanalysis does not make 'points,' but 'lines' ('On *A Thousand Plateaus*', in *Negotiations*, 33); it is closer to Bacon's pictorial experiments and therefore closer to 'meat' than to the 'flesh' invoked by phenomenology.

---

[9] For Deleuze, the distinction Badiou makes between truth (*vérité*) and the veridical (*véridicité*) does not exist. For truths are confined to the domain of knowledge (*savoir*) and do not harbour an evental dimension as they do in Badiou's philosophy.

[10] 'There are imbecile thoughts, imbecile discourses, that are made up entirely of truths [...]' *Nietzsche and Philosophy*, 105.

[15] A. Badiou, *Deleuze*, *op.cit.,* 11.

[16] I owe this expression to Guillaume Destivère. Further, he adds: 'from this point of view, [Deleuze] has preempted Badiou, "the intermediary of encounters with truths", on all fronts. And Badiou knows it.' (personal correspondence).

[17] Indeed, we should note that if the sophists insist on the question of nature, convention, and the concrete, it is Parmenides himself that reminds the young

philosophy. The Badiousian stratagem backfires, for Deleuze is truly Spinozist. Philosopher *sans Cogito*, he is also a philosopher of the concept, which is to say a para-*doxa*-cal philosopher. In this, he is a philosopher of complete freedom, meaning absolute necessity and power. On this point, the Stoic and the Spinozist, quite coherently and logically, are as one – *as ethicists*. So that Deleuze, this considerable contemporary, himself finds a place in the subterranean and volcanic line of rare philosophers who are irreducible to the official history of philosophy. *A life* – 'It is at this mobile and precise point, where all events gather together in one that transmutation happens: this is the point at which death turns against death; where dying is the negation of death, and the impersonality of dying no longer indicates only the moment when I disappear outside of myself, but rather the moment when death loses itself in itself, and also the figure which the most singular life takes on in order to substitute itself for me.'[18]

This is why there is nothing but the nomad.[19] That which 'deterritorializes,' crosses boundaries, goes beyond limits in order to go to the end of its powers, which distributes and is distributed in a smooth space. It is that which, because it is a pure multiple, *consists* and thus cannot be

---

Socrates of the rights of hair, dirt, and mud to benefit from an appropriate Idea.

[18] *Logic of Sense*, 173-4.

[19] The nomad, who, although quite capable of austerity, is *desiring*, and thus certainly does not pursue the ascetic ideal stigmatised by Nietzsche.

subdivided.[20] We could call 'nomad's checkmate'[21] the move that Bergson's Riemannian disciple intuitively pulled off against Badiou,[22] the ex-Maoist turned Platonist. From *Theory of the Subject* to *Being and Event* to *Logics of Worlds,* Badiou refuses to abandon a non-phenomenological concept of the subject, inspired by Lacan, but brought together with post-Cantorian mathematical set theory as well as category theory. We must distinguish between conceptual personae here: the preeminence of the nomothete[23] over the judge is the preeminence of the one who constitutes over the one who is constituted. In passing from the former to the latter, something is lost. The distinction is neither dialectical nor logical; it is *ethical.* For joy differs, absolutely, from sadness, power from helplessness. He who gives the rule is free, while he who judges *according* to the rule is free only through the mediation of the rule which constitutes him, and through servitude to the rule he institutes. Such is the meaning of this heterological representative operation: For the hot cruelty of the theatre lauded by Artaud, and for crowned anarchy, is substituted the internal coldness of the world of Masoch, who, *aparallel* and heterogeneous to sadism, establishes a suspension of the law of the institution, by means of the contract. Which can be summed up thus: pleasure is the benchmark of *a desire that lacks nothing* since, according to the classic axiom and the Parmenidean (which is to say pre-anti-Platonic) legacy, *nothingness has no properties.*

---

[20] Here, the psychoanalytic *Ichspaltung* and Lacan's divided subject are to be contrasted with Artaud's BwO, the Deleuzian planomenon, or the intensive multiplicity posited by Bergson, which differs from extensive multiplicity (divisible *partes extra partes*); being 'defined by the number of dimensions it has […] it cannot lose or gain a dimension *without changing its nature*. Since its variations and dimensions are immanent to it, *it amounts to the same thing to say that each multiplicity is already composed of heterogeneous terms in symbiosis, and that a multiplicity is continually transforming itself into a string of other multiplicities* […]" (*A Thousand Plateaus*, 249).

[21] 'Nomad's mate' (*mat du nomade*) alludes to – and contrasts with – the 'Shepherd's mate' (*mat du berger*), a chess move known in English as the 'Scholar's mate'.

[22] Indeed, for Bergson, it is within intuition that the absolute is given. If it is not a question of *intellectual* intuition, which Kant refused Plato, neither is it a question of sensible intuition. It is more a matter of *metaphysical* intuition, which is not an intuition of immutable essences or simple phenomena. Instead, it is the intuition of pure duration conceived as indivisible time and considered as *in-itself*, given that 'reality is mobility itself.'

[23] 'The philosopher […] is legislator.' 'Nietzsche', in Deleuze, *Pure Immanence*, 66.

In conclusion, if effects of transcendence do indeed occur, it is only qua denaturing of pure immanence, a denaturing whose frequency gives the exact measure of the rarity Badiou attributes to the event. For it is a commonplace that the conflict between Deleuze and Badiou's philosophies lies essentially in their respective articulation of the concepts of the whole [*tout*] and of the set; at least, this is the ambiguous *postmortem* angle of attack taken up by Badiou, holed up in the citadel of set theory.[24] If Kant makes of totality a category of understanding (under the rubric of quantity) and presents it as a synthesis of unity and plurality, for him it will consequently be a question of a principle of closure. For such a synthesis forecloses plurality, that is to say it makes it a whole through the mediation of unity. Deleuze, on the contrary, defines the 'whole […] through relation' specifying further that relation is 'not a property of objects.' The relation is 'exterior to its terms',[25] and belongs to the 'whole' on condition that the whole is thought in an exceptional way, *i.e.* not as quantity, but as *continuum*, as an indivisible continuity[26] like a 'thread' that connects sets and keeps them open. Thus it is a question of a *nomadological autonomisation of the relation*,[27] a process which consitutes the originality of Deleuzian ontology,[28] and not a mere devaluation of the 'closed,' as Badiou would have it. The latter asks: Which infinity? Which multiplicity?[29] Deleuze, however, has already responded: not with the One-All, as the master mathematician of the rue d'Ulm affirms, but with *a* multiplicity, the whole as 'paradoxical link',[30] the event as 'lightning'.[31]

---

[24] However, the brief note dedicated to *Being and Event* in *What is Philosophy?* (151-2) seems almost to justify such an attack.

[25] *Cinema 1: The Movement-Image*, 10.

---

[26] 'The real whole might well be, we conceive, an indivisible continuity' (H. Bergson, *Creative Evolution*, trans. A. Mitchell, NY: Dover, 1998).

[27] A relation that, as we have seen, is external to the terms that effectuate it (and which thus *become* through the relation's intervention). Therefore, the relation is not a correlation, but rather constitutes the properly Deleuzian absolute; the relation not as being or necessary essence, but as event, or in Nietzschean terms, as '*Himmel Zufall*.' In particular, it is of course not easily assimilated to the 'count-as-one' of set-theoretical belonging.

[28] More so, in fact, than the primacy Deleuze grants to Life, or even to Difference (which he declares, during the period of *Difference and Repetition*, is 'in the air of the times'), particularly through the notion of the structuralist-inspired 'differential relation'.

Responses to a Series of Questions[1]

Gilles Deleuze

Arnaud Villani: Are you a 'monster'?

Gilles Deleuze: To be a monster is first of all to be composite. And it's true that I have written on apparently diverse subjects. But 'monster' has another meaning: something or someone whose extreme determinacy allows the indeterminate wholly to subsist (for example a monster à la Goya). In this sense, thought itself is a monster.

AV: *Physis* seems to play an important role in your work.

GD: You're right, I believe that I turn around a certain idea of Nature, but I have not yet arrived at considering this notion directly.

---

[1] This exchange between Arnaud Villani and Gilles Deleuze took place in November 1981, and appeared in A. Villani, *La guêpe et l'orchidée* (Paris: Belin, 1999), 129-31.

COLLAPSE III, ed. R. Mackay (Falmouth: Urbanomic, November 2007)
ISBN 978-0-9553087-2-0
http://www.urbanomic.com

AV: Can we call you a 'sophist' in a positive sense – has the *antilogos* returned, despite Plato's attack on the Sophists?

GD: No. For me the *antilogos* is connected less with the tricks of the Sophist than with Proust's 'involuntary'.

AV: Thought is 'spermatic' in your work. Is there a clear relation, in this sense, with sexuality?

GD: That was the case up until *Logic of Sense*, where there was still a specifiable relation between sexuality and metaphysics. Afterwards sexuality seemed to me rather to be a badly-founded abstraction.

AV: Could we trace your evolution in terms of syntheses?

GD: I see my evolution otherwise. You know the 'Letter to a Harsh Critic':[2] that's where I explain my evolution as I see it.

AV: Thought as provocation and adventure?

GD: In what I have written, I believe strongly in this problem of the image of thought and of a thought liberated from the image. It's already in *Difference and Repetition*, but also in *Proust and Signs*, and again in *A Thousand Plateaus*.

AV: You have an ability to find, despite everything and everyone, true problems.

---

[2] *Negotiations*, 3-12.

GD: If that's true, it's because I believe in the necessity of constructing a concept of the problem. I tried to do so in *Difference and Repetition* and would like to take up this question again. But practically speaking, this approach has led me to ask, in each case, how a problem might be posed. It is in this manner, it seems to me, that philosophy might be considered a science: the science of determining the conditions of a problem.

AV: Is there a beginning of a rhizome Deleuze-Guattari-Foucault-Lyotard-Klossowski-etc.?

GD: That could have happened, but it didn't happen. In fact, there is just a rhizome between Félix and myself.

AV: The conclusion of *A Thousand Plateaus* consists in a topological model which is radically original in philosophy. Is it transposable into mathematics, biology?

GD: To my mind, the conclusion of *A Thousand Plateaus* is a table of categories (but an incomplete, insufficient one). Not in the style of Kant, but in the style of Whitehead. So that 'category' takes on a new, very special sense. I would like to work more on this point. You ask if a mathematical or biological transposition is possible. No doubt it is the other way around: I feel that I am Bergsonian – when Bergson says that modern science has not found its metaphysics, the metaphysics it needs. It is that metaphysics that interests me.

AV: Could it be said that a love of life, in all its frightening complexity, has informed your work all along?

GD: Yes. This is what disgusts me, in theory as in practice – every type of complaint in regard of life, every tragic culture, that is to say, neuroses. I really can't stand neuroses.

AV: Are you a non-metaphysical philosopher?

GD: No, I feel I am a pure metaphysician.

AV: In your view, can a century be Deleuzian, light? Or else are you a pessimist as to the possibility of our being delivered from identity and the power of traces?

GD: No, I'm not at all pessimistic since I don't believe in the irreversibility of situations. Take the current catastrophic state of literature and thought. To me, that doesn't seem grave for the future.

AV: And after *A Thousand Plateaus*?

GD: I just finished a book on Francis Bacon, and have only two other projects: one on 'Thought and Cinema' and another which will be a large book on 'What is Philosophy' (taking up the problem of categories).

AV: The world is double, macrophysical (where the image of thought works well enough) and microphysical (and your model, years after the same revolution in science, in art, takes account of this in philosophy). Is there a polemical relation between these two points of view?

GD: The distinction between macro and micro is very important, but it belongs more to Félix than myself. For me, it's more the distinction between two types of multiplicities. This is what is essential for me: that one of these two types refers to micro-multiplicities is only a secondary consequence. For the problem of thought, just as for the sciences, the notion of multiplicity, as introduced by Riemann, seems to me more important than that of microphysics.

'I Feel I am a Pure Metaphysician': The Consequences of Deleuze's Affirmation

Arnaud Villani

I have often noted the remarkable extent to which, since 1981, this affirmation[1] has transformed the major axes of my interpretation of Deleuze. And for good reason: In an anti-metaphysical epoch wholly occupied, in Heidegger's wake, with 'overcoming metaphysics as one overcomes tears', here is a philosopher who dares to affirm his filiation with Bergson and Whitehead. It is important first of all not to doubt the sincerity of his remarks, and this against the tendency (Cressole, Badiou) that would attribute to Deleuze postures devised primarily with a view to the effects his words would have upon his students. Furthermore, it is important explicitly to draw out their consequences for his philosophy, and then for philosophy as a whole. This is what I propose to do here.

COLLAPSE III, ed. R. Mackay (Falmouth: Urbanomic, November 2007)
ISBN 978-0-9553087-2-0
http://www.urbanomic.com

To understand what is at stake in this formula, we must reprise the problem of the moral and the political. In *Précis de philosophie nue*,[2] I tried to develop the hypothesis of a sort of immanent eternity, an eternity of this earthly life, in so far as every second of a person's life, properly scrutinised, offers, both in sensibility (the senses, sensuality, the passions) and in thought, a kind of infinite opening. Sensoriality (affectivity) and thought are hypercomplex spaces, given over to the infinite. Nothing limits them, either in space or in time, and not only because they often unfold outside space and time. We could, in very classical terms, call the first sphere 'aesthetic', the second 'noetic'. It might be thought that this infinity (so keenly felt in the descriptions of Virginia Woolf, James Joyce, and in Roussel's *La vue*) owes to the fact that the given, offering something upon which to nourish and develop sensibility, passion and thought, never really constitutes an obstacle for them. It is not the *subject* of these domains, but rather their *object.* When we consider the practical sphere, on the other hand, the status of the external given is inverted. It becomes all-powerful, authoritarian, inflexible. Not without reason do we speak of 'brute fact'. And the whole problem of the practical sphere consists in circumventing this resistance, in coming to terms with it or accommodating it, or most often in vanquishing it as one does an enemy.

Therefore the practical sphere better deserves the name of 'drastical'. This is the name I will reserve for it, considering, apart from the sense of the verb *dran* in Greek (to act), that the complexity that characterises the first two spheres must, in the act and in the 'decision' that precedes it, be *firmly, pitilessly restrained in order to become effective*. But is not such a restriction also to be found in sensibility (as was understood by Bergson, for whom the colour red was the 'summary' of trillions of vibrations per second), and even in thought, since all noetic activity is subject from the very beginning to the severe limitation of the terms in which it is developed? For to think without language is impossible; and words, by themselves, apart from their relations with others, are never susceptible to *infinite* modifications, nuances or distinctions.

---

[2] Nice: Éditions de la revue NU(e), 2005.

Certainly, sensibility and thought must be entrusted to a language in order to become effective (*wirklich* – it is the spirit of this word which commands Hegel to eject from the dialectic the crazy riches of 'sense-certainty' and its appearances, incapable of being *spoken*). But the proof that these two domains harbour an open infinity is the eagerness exhibited by totalitarian systems in trying to check them. Whereas the practical consists essentially in a *choice*, in a *drastic reduction of complexity*, a gesture that could be likened to that of Procrustes, when he stretched or sliced travellers to make them fit his bed. To choose is to endow one's act with a meaning, by depriving it deliberately of that which one does not choose. Thus political choice, moral choice (Hercules before the roads of vice and virtue), the choice of a unique method in the domain of technique and science. The anguish of choice is the *angustiae*, the narrow defile through which we must pass.

I will provisionally make the following remark: If Deleuze is able to convince a neophyte from the word go of the considerable importance of his philosophy with regard to questions of art and to all that pertains to sensibility, affect, a 'new image of thought', his work poses redoubtable problems of interpretation when one considers its ethical and political leanings. Since up until now its most profound basis has not been interrogated, this difficulty has engendered lines of argument as erroneous as can be, interpretations which literally invert the Deleuzian philosophy and contradict its most frequently affirmed and reiterated postulates. All of which should be a first warning for us: we must not take lightly Deleuze's affirmation of a metaphysics. It concerns his whole philosophy. In other words, it invites us to rethink in a new light, in this great philosopher of freedom, the relations between sensibility, thought and action. And in particular, to consider the reasons why – as might also have been the case with Nietzsche's 'great politics' – the work of a very great philosopher for whom the infinite in thought and in the senses were always of the first importance, seems to end up with apparently fugitive arguments, or *prima facie* disappointing solutions, in the domains of the moral and the political.

CONSTRUCTING A MODEL OF COMPLEX ACTION

Let it be understood: it is not a matter here of developing a gnoseology of complexity – although it could indeed be said that the latter is a feature of Deleuze's philosophy, in the use he makes of Bergson or Leibniz, and in the theory of *multiplicity*, *rhizome* or *chaosmos*. But for us, from now on, it will rather be a question of understanding the *severance* which, it is said, separates the sensible and intelligible spheres from that of action. Sensibility has no limits, thought can go to infinity, without even speaking of the relations of sensorial sensibility to the sensibility of sentiments, of the relations of sensations between themselves, of relations between all thoughts, and finally of relations between the two spheres. But the *acts* which they permit (and which permit them) rest upon the *decision* (trenchant by definition) to refuse the infinite. Now, the metaphor for the act has remained unchanged since the 'epactic discourse' attributed to Socrates.[3] *Agô* for a horse-breeder, is 'to make the heads of cattle advance by driving them before oneself, to make them pass, one by one, from the dispersion of the pasture into the confinement [denumerable, and this is even probably the moment of the invention of numbers] of the enclosure'. *Agô*, which is found in our 'action', always has a drastic aspect. It abbreviates a natural complexity into a cultural simplicity.

For the choice to be a choice, it must restrict the field, it must effect a passage from a volume to a surface, from a surface to a line, from a line to a point. But let us admit that complexity can be compacted or abbreviated into a point without being lost (the thematic of naturing-nature) and that once the eye, the sluice, the threshold, is passed, it will redeploy itself by *spacing itself out*, by once again taking on volume. Let us admit then that choice will no longer be a matter of fleeing complexity or of making 'difference expire', and refuse to harden *airêsis* (the differing choice) into an unpardonable heresy, or the divergent political position into a one-way ticket to the scaffold or the gulag. Would this not then be a fine genealogy for the Deleuzian theory of *inclusive disjunction*?

---

[3] The epactic model of discourse (as in Plato's *epaktikoi logoi*) insists upon an ascent to the absolute definition of concepts before discussion commences – hence the Platonic quest for the Idea. But the original sense of the Greek verb *épagô* is 'to drive a herd before one', in other words to make a diversity of dispersed animals pass into the unity of an assembled herd in the enclosure.

The model that I put forward borrows from Bergson, in pursuing his intuition. It is that of the *double cone*: The problem of action, whether political or moral, is visibly concentrated at the 'bottleneck' through which the content of the first cone passes into the second – the image of the hourglass. Now, precisely, choice is always a function of time. We might say that urgency is the mother of choice. Choice is 'pressing'. A space (to be defined) of complexity, one image of which might be the coexistence of virtuals or 'pure memory', coincides with another space through the uncircumventable tract of a temporal passage. The grains present themselves – a 'presentiment' of themselves – at the bottleneck. To succeed in endowing each grain with the 'spirit of complexity' represented by the whole to which it belongs – this could, as in the Battle of the Caudine Forks, free this spirit, make it once more occupy the whole space. In Husserl, this would be the problem of present attention, the thin line, the points between the trailing lines of retention and protention. In Deleuze, the problem would be at least as complex, with the special status of the 'and', the *aiôn* which 'leaps over' the present like a formal narrowing of time, or again, the suspension, in the evolution of cinema, of the 'sensori-motor' and intrigue, which are completely aligned with the impoverished model of action, in a 'neo-realism' capable of redeploying affects and percepts in all their proper richness.

In the virtual (in what Bergson calls 'dream') there is nothing but energy; no forces or forms. There is no opportunity to collapse the quantum wave function, to distribute it into assignable particles. But in dream, in narcotics, in surrealism, in the non-act, the *real* is lost. And here is precisely the occasion to redefine the latter more conceptually. The 'real' in Deleuze would be the *inclusive disjunction of the actual and the virtual, of intelligent sensibility and action.* For it is evident that the tendency to define the real in terms of action and 'fact' is the naïveté proper to traditional thinkers when they succumb to a kind of narrow thinking. The true problem (and thus philosophy) begins when one tries to think the relation of the ideative sphere, in all its richness, and the sphere of action, in its apparent poverty – if you like, the relation between qualitative multiplicity (free repartition in the whole field) and quantitative multiplicity (where, the elements being significantly reduced, they can be tracked 'by eye' and each individual located within the field) – the two senses of the radical **nem-*.[4] In a word, the relation of the heterogenising and the homogenising. How to make of action a multiplicative, potentialising, opening movement? How to do politics without totally quitting poetics? How to keep intelligence and sensibility in action?

As will have been understood, the opposition is not, to a great extent, between sciences and art, technique and philosophy, politics and poetics; but rather, in each domain, between that which opens and multiplies and that which closes and restrains. The theory of infinite sensibility – which I call *sursensibility* – analyses those moments where sensibility is married with other faculties and rises to power, producing the synergy of intelligence, memory and imagination. Kant sketched this possibility in the aesthetic idea, 'which prompts much thought.'[5] In *noetics*, contemporary thought makes up for lost time in seeking all possible means of developing a 'complex thought'. We must be attentive, however, to what philosophy already has to offer from this point of view, with the 'thinking of totality' or 'inseparate thought' of myth and of the first Greek thinkers; with the 'symbol' in the pre-Socratic and tragic thinkers; 'hyperbole' in Hölderlin; the 'choice of choice' in Kierkegaard; the 'interval' or 'dialectical passage' in Hegel and Bergson. For its part, contemporary epistemological research continues to privilege complexity, with Atlan's 'self-organisation', Morin's 'ternary concept', the 'homeorhesis' of theories of flows, and Bertalanffy, von Neumann and Luhmann's 'systems theory'.[6]

If metaphysics can be called the science of the highest realities, the 'first' realities in all senses of the term, do we not have here the means of endowing this venerable 'science' with a reality which resists enclosing it in the corsets of general and special metaphysics? Wouldn't the first fact of metaphysics as first science be this difficulty of doing justice to complexity, to multiplicity, to singularity, to the 'density' which the poet Hopkins means to signify when he tries to give an account of the astonishing 'burl' of a divine real? If rite, myth and religion can translate the overflowing *feeling* which results from the first fact of the infinity of the 'real' (a sort of 'I believe', an adhesion to a type of 'faith', an unreflective 'natural attitude'), *metaphysics* might be the decision *in thought* to reflect upon the possibility of *giving a full and*

just account of this hyper-physical infinity. But then, could one imagine any problem which better articulates what is at stake here, than that of thinking the loss that accompanies certain modes of thinking, and all action in general? To pose this question in all consciousness, is to be a metaphysician. And I wager that Deleuze, in calling himself, and in feeling himself to be, a pure metaphysician, wanted first of all to bring this idea, this problem, to the fore.

THE METAPHYSICS OF COMPLEX ACTION

We begin with a commonsense remark: The epoch of gods (Gods) and of transcendent objects is not all that old. A few thousand years ago, there were only intensities. It is the *sacer*, denoting the fearful reception of intensity, that in *religio* is translated into the precondition to every manner of ritualising, phrasing, and transforming intensity into names and dogmas. Now, these intensities, even if they refer to hypermundane realities, are nevertheless themselves *of this world.* It is in this world that we experience them. What Hegel and Feuerbach after him saw, and rightly no doubt, as the projection of the 'part of the immutable' or of the 'figure of the ideal' in a 'wholly other' or an elsewhere, begins with that mysterious frontier between the internal and external where shamans little by little imposed the idea of the soul, capable of a 'delocalising' voyage. Metaphysics begins when the possibility is perceived of a distinction still more radical than that between internal and external, thought and action, the animate and the inanimate. Metaphysics, in its classical form, seems to be born when something comes to light of an absolute difference, a difference in nature, between the intensity which endures forever or preserves itself, and the intensity which ends by declining, diminishing, being abolished.

The tendency of metaphysics, and of a religion that has cut its links with paganism – that is to say, with a certain *natural* unity of intensity and non-intense space – consists in a most risky wager: concentrating all intensity into an unreachable and unexperiencable space, into a hyperbolic Beyond, which thus benefits from all the 'great words' that make us dream: Ideal, Absolute, Infinite, Eternal, Sublime, Immutable, All-Powerful, etc. Pondering this more closely, one finds here a thinking of the *razzia*: the plundering of all the riches of one place and their transference *en masse* into another, preferably hidden (*adêlon*). The Greeks and Romans understood each other quite well when it came to this art of razing whole towns, leaving nothing behind in their wake.

In other words: to have done with the intensity of this world and to repatriate the Infinite and the Too-much into 'heaven'. Religion and metaphysics will then be arranged so as to 'breath' and 'ventriloquise', each on its own account, the revelations of the Absolute in person (what Nietzsche calls 'the telephone to the beyond'), revelations which only the initiated can grasp and interpret. It will then remain only for them to trace thought and action – which remain (whether one likes it or not) in the intramundane – from these phrases emitted by the Absolute. So many metaphors and apophatic warnings are deployed from on high that it will be necessary to suggest this place devoted to '*to mê dunon*', that which never sets.

One might think that things have moved on and that we are now grown-ups, having attained 'majority' as Kant hoped. If it is undesirable to put down these great constructions of the imagination, of thought and sensibility – whose architectural equivalent indicates at least that the 'divine places', according to Jean-Luc Nancy's fine thought, are valued for their 'volume' and not necessarily for their content[7] – on the other hand it is more than time to return to *intramundane intensity*. Which comes back to saying – and this is exactly the meaning of the formula 'God is dead' and, in its positive aspect, Nietzsche's cry 'long live *physis!*', that it is from 'down here' that the riches of the sensible and of the thought which is devoted to it, must come forth, as we ourselves do. Our problem is no longer that of sacrificing these riches by forcing them through the disfiguring defile of a 'narrow gap', so as to find them again, supposedly transfigured, there where there is in all probability neither world nor sense to perceive them. We have not changed the statement of the problem: 'How to save the richness of the instant?' But we have modified its implications. An immanent metaphysics does not save the world by throwing it overboard, it examines the possibility of preserving the immanent riches of sensibility and thought in synergy, in an action which might perpetuate and *live up to* them. It appears then that the first coherent gesture of a metaphysics of complex action consists in developing a theory of art. And this is what, incontestably, Nietzsche and Deleuze succeeded in doing.

Hegel, who exploits the breach opened up by Kant towards a metaphysics of immanence, but proves equally unable to bring the project to fruition, proves most lucid when he opens the *Phenomenology of Spirit* with the central problem of *Sinnliche Gewissheit* ('*Sense-Certainty*'). We know his response, which consists in the immense detour through the *Phenomenology* itself to recuperate *in fine* this dazzling certitude of the sensible finally reconciled with Spirit. This response disappointed the great art-theorist Maldiney. He did not hesitate, in his *Regard, parole, espace*,[8] to denounce it as a 'false beginning' for phenomenology. For every artist, as we know, even if his work is particularly *pensive*, departs from this marvellous intuition to which, in a sense, his work pays homage. The only theorist, I would say, who permits us to see clearly in this debate, a debate whose essential importance it is time to consider, is Ehrenzweig. His idea of a 'labyrinth of creation' (exposited in *L'ordre caché de l'art*)[9] already constitutes a theory of complex action. He maintains convincingly that a series of decisions (concerning for example the relation of two neighbouring colours) can come, in the best of cases, to endow *action* (the ensemble of gestures which constitute the work) with as many riches as can be comprised in sensibility, imagination, memory and thought, as comprised in 'the experience' of the artist.

Recall also that Deleuze's *Logic of Sensation* shows how Bacon's creative act liberates the canvas from all that is opposed to the 'rising of the wave of sensation'. It is more than likely that a similar study of his *Proust and Signs* would see in the involuntary, conceived as 'the spider's strategy', a way of bringing forth intensities and liberating them within the act itself. It would not be difficult, once the problem of immanent metaphysics in Deleuze is seen as the *isolation of*

[9] Paris: Gallimard, 1982.

the conditions of possibility for a complex act, to find this problem in the theory of the concept, in disjunctive syntheses, or in the fold. All these assets could be summarised as part of the effort to allow the 'encounter' to deliver all its power, to go, as he says, 'to the limits of what it can do'.

A TYPOLOGY OF COMPLEX ACTION

We seek an action which frees, unshackles, opens before the event (the flow which comes to encounter another flow) a smooth space, without 'frictions' to restrain it, which will permit it to *liberate the architectonic volume* which it comprises (this concern is manifest, for example, in Deleuze's *Kant's Critical Philosophy*). Such an action would be as complex as the intelligent sensibility that was its source – the 'drastic' would have the same status as the 'aesthetic' and the 'noetic'.

First of all – and without insisting on this, since Deleuze himself does not allude to it – one might, in the margins of this typology which alone can lead to a 'superior empiricism' (that is to say one *where action would not be condemned to an essential poverty*, but would 'overflow'), would suggest a new interpretation of *mimesis*. I mention this possibility because many of the questions I posed to Gilles Deleuze in 1981[10] turned around a Romantic reading of '*physis*'. As Aristotle, the inventor of the formula, knew, and as the Romantics rediscovered in the 'sentiment of (the power of) nature', *mimesis physeôs* never has anything to do with an 'imitation of the natural', but everything to do with a contagion of naturing forces. The 'intelligent sensibility' of the Romantic Friedrich, that of Monet or of Sisley, that of Macke or of

---

Kandinsky during his non-figurative breakthrough in the period of the *Blaue Reiter*, leads, as if 'involuntarily', to the only pictorial gestures capable of rediscovering, at the end of action, the full complexity which initiated the attempt.

I could say the same of another action in which it would be difficult, in truth, to distinguish between the conception of action and action itself. I mean the *ruse*, that veritable constellation of intelligence which escorted Greek thought and *praxis* continually for six centuries. Detienne and Vernant's analyses[11] have brought to light the necessary qualities of mind and the essential grasp of the 'favourable time', the 'opportune moment' (*Kairos*). We must understand these requirements once more. To my eyes, they wholly coincide with the idea of *punctualisation*. The spirit must be acute (*agkhinoia*) and apt at conjecture (*eustochia*), but the situation must be analysed *in its widest context*. Hegel insists also on the ruse's acute, 'piquant' aspect: He employs the radical **ak*- to designate its *fine point*.[12] Comprised in this image is the *bottleneck* of the hourglass of which we spoke at the outset: the nondenumerable overflowing of the temporal and spatial situation must be *concentrated* in the favourable instant, characterised, let us not forget, as *the instant which will never return*. For just one sole instant is capable of realising this *aleph*, this *maximum in minimo* of the theologians (namely the *Virgin's womb*), an immense space concentrated into a point and awaiting its redeployment. On this condition, action might recuperate all the tenor of sensible intuition and the reflection upon its components – an action which is complex in so far as it harbours what is effectively the counterpoint of the situation, marries itself to the fluctuation of things themselves, and, respecting the 'way of things' by furnishing their image in negative, permits not only the unscathed exit from a potentially deadly impasse, but even gives us the perfect example of a true 'act of knowledge'. 'To act in full knowledge of the facts', as Aristotle's 'prudence' would have it (that *phronêsis* analysed so ably by Aubenque)[13] – this expression might well find a more profound sense here.

---

[11] See M. Detienne & J-P. Vernant, *Les Ruses de l'intelligence: la mètis des Grecs* (Paris: Flammarion, 1974).

[12] In the *First Philosophy of the Spirit* – See G.W.F. Hegel *System of Ethical Life and First Philosophy of Spirit,* ed. trans. H.S. Harris & T.M. Knox. (NY: SUNY Press, 1979).

If the imitation of naturing and the intelligence of the ruse might constitute the first types of complex action – both, let us note, relating to the force of 'nature' as all-overflowing and undulating situation (Nietzsche's 'tempestuous sea' of the real) – they do not, however, tell us *how* sensible intelligence transforms itself into action. The moment of passage remains mysterious, and neither Hegel nor de Certeau managed to penetrate its secret. It would seem that Deleuze dedicated a large part of his work to inquiries concerning this passage. And if he said that I 'mediterranianised' him,[14] it is because he must have felt how this inquiry led back – for me, in any case – to Greek thought. Consider firstly to what extent he privileged in Spinoza *active* passions, in Nietzsche *active* forces. Examine the concept which he borrows, in fine Deleuzian fashion, from Spinoza: *expression*. It could be summed up by speaking of 'that which follows from the necessity of a nature'. Equally, note the following: Not only does he distinguish, in the three syntheses, the immanent which opens, juxtaposes and potentialises, from the transcendent which, each time, ends in an *overnarrow* gesture, extracting substance, proscribing one of its possibilities, releasing responsibilities. He already produces a *theory of the act* which is entirely continuous with the increase in power of sensibility and intellection: this can be seen in Daphnis and Chloé's 'so this is love'; for when it happens, love is as much a new sensibility as a brusque comprehension of life and the opening of a field of infinite action. The immanent conjunctive synthesis is an *intelligent and sensible act.*

[14] See Deleuze's letter, reproduced in A. Villani, *La guêpe et l'orchidée* (Paris: Belin, 1999).

In general fashion – and this proves to what extent this problematic of action is central in Deleuze's work, even if it never appears in explicitly thematised form – everything comes back to the theory of difference. As Deleuze perfectly understood (but what *didn't* he understand?), difference 'alone' is pure chaos, for it cannot be referred to anything that would even allow it to be apprehended. A difference in potential is necessary to allow a sensation to be apprehended, but sensation is a *series of sensations*, thus a difference of differences of potential. Inversely, when articulated through the identical, difference is sequestered into an identitarian logic which makes it pass to a secondary plane – that is to say, annuls its singularity. There remains, then, just one other possibility, which Deleuze calls 'difference *and* repetition'. It is a question of producing an (infinite) series of differences of differences, of differences '*en bloc*', producing the movement of all these differences differing from themselves at every moment; in short, the rhizome, the bloc of memories or sensations, heterogeneous continuity, the fold. So that *the fold appears to us as the 'concept' of every complex action* in so far as it perpetuates the intelligent sensibility from which it originates and no longer leaves any visible scission between knowledge and action. The fold is an *act of sensible intelligence*. It is obviously on the basis of such reflections, germane to Deleuze's thought in its detail and as a whole, and only upon them, that we must try to elaborate with all the necessary finesse the Deleuzian/Guattarian concept of micropolitics. But this will be the object of another study.

CONCLUSION

Why are totalitarian ideologies forever the shameful impasses of History, those where humanity did not merely go astray, but in a sense saw its hideous limit appear in outline, like the skull-and-crossbones of a pirate crew preparing to board? Because, not content with developing a sub-sensibility (indifference to the other, sadistic hatred, insensibility to compassion, affected sentimentality, a passion for death and suffering) and a sad caricature of thought, they *dessicated, as do all tyrannies, the very root of action.*

The act contents itself with being the irreflective obedience to order-words, however inhuman they might be. As to the acts of those in charge, they are designed to suffocate all liberty to act, every active invention.

Inversely – and this may well sound like the very model of art according to Nietzsche (as I tried to show in the *Cahier de l'Herne* dedicated to that author)[15] – the act of creation does not even achieve its highest complexity in the 'masterpiece'. The greatest creator is he who creates 'something with which to create' (I have called this, on the model of the Aristotelian 'thought of thought', a '*physis physeôs*', a 'production of production'). More generally, before dreaming of moving on to a 'post-Deleuzianism', as seems a fashionable wish, have we truly drawn all the possible usage from Deleuze's insistence upon the difference between *active* and *reactive* forces? In his work there is a profound reflection on action. For my part, I will continue to prefer a system where the aesthetic and noetic are as open, multiform and complex as they can be when one welcomes with rigour the requisites of an immanent metaphysics: that is to say a philosophy of the infinite, even if the 'drastic' must remain *pointillist*, precisely because a theory of their relations, whether in Deleuze or in Nietzsche, remains in part to be developed. For if, inversely, the drastic is affirmed, programmed, hammered home, whilst the other two spheres remain simplistic and narrow, superficial and embryonic, action will be nothing more than the effect of its own declaration or, as Deleuze feared, this series of 'order-words' which, alas, we are accustomed to call 'language'. What is more, who does not see that sensibility and thought taken seriously and *rising to power*, indicating their infinite nature, are themselves *already* actions? When Deleuze redeploys Plotinus and his theory of contemplation, this is what he wishes us to understand. There will be then only one object of metaphysics conceived as immanent: active (creative) sensibility, the act of intellection (and not solely intelligence *in act*); and an action, ultimately, which, far from immobilising the real, takes up arms with it, finally liberating its immense virtual forces.

Subtraction and Contraction: Deleuze, Immanence, and Matter and Memory.

Quentin Meillassoux

In memory of François Zourabichvili

We begin with a remark from Chapter 2 of *What is Philosophy*?, which discusses the plane of immanence. This book, of course, is by Deleuze and Guattari, but the text, in this case, clearly indicates a Deleuzian provenance:

> Spinoza was the philosopher who knew full well that immanence was only immanent to itself and therefore that it was a plane traversed by movements of the infinite, filled with intensive ordinates. He is therefore the prince of philosophers. Perhaps he is the only philosopher never to have compromised with transcendence and to have hunted it down everywhere.[1]

Further on, Deleuze writes:

> Spinoza is the vertigo of immanence from which so many philosophers try in vain to escape. Will we ever be mature

> enough for a Spinozist inspiration? It happened once with Bergson: the beginning of *Matter and Memory* marks out a place that slices through the chaos – both the infinite movement of a substance that continually propagates itself, and the image of thought that everywhere continually spreads a pure consciousness in principle (immanence is not immanent 'to' consciousness but the other way around).[2]

There are at least two ways to approach such a text. The first way – the most natural way – would be to try to understand by applying oneself to a more in-depth reading of Deleuze. This would necessitate, for example, an elucidation of what Deleuze means by 'plane of immanence' or 'chaos'. It would also mean resituating this text in the light of Deleuze's *Cinema* – and more especially in the light of the two commentaries in *The Movement-Image* dedicated to the first chapter of *Matter and Memory*.[3] But there is a second way of approaching this text, and it is this alternative that we shall pursue here. It might at first seem somewhat artificial, but we hope that its aim and its interest will rapidly become evident.[4]

In what, then, does this reading consist? No longer in trying to understand the text in question on the basis of a certain reading of Deleuze, but in trying to understand – or to better understand – Deleuze, on the basis of a certain reading of the text. In other words, it consists of making this text, not the *object*, but the *instrument* of the elucidation.

[3] *Cinema 1: The Movement-Image*, Chapters 1 (3-12) and 4 (58-72).

[4] Although this article is concerned with the link between *Matter and Memory* and Deleuze's philosophy, we will make no further reference to the analyses in *Cinema* of Bergson's masterwork, and the reader may, quite rightly, be surprised at this. But our aim is to clarify, to grasp the intimate relation between these two thinkers, something which is not the same as undertaking an exegesis of those Deleuzian texts expressly dedicated to Bergson. Our path, as will be seen, is constructive, not exegetical. And although the convergence of these two perspectives – that of reconstruction and that of commentary – may naturally follow from our enterprise, this cannot be fully demonstrated within the current article.

To understand this point of view, let us place ourselves in the following imaginary situation: let us decide to read Deleuze as a pre-Socratic, of whose writings we possess only a few rare fragments, including the text in question, which we will call the 'Fragment of the Double Crown' since in it two philosophers are said to be princes. To these fragments, we must add a 'life' of Deleuze by Diogenes Laertius,[5] which teaches us little, apart from the fact that he was known as an original philosopher, rather than as a simple disciple of Spinoza or Bergson; and that his philosophy was known as a philosophy of immanence. This very term, in its banality, means nothing more precise to us than those terms such as 'water', 'air' or 'fire' which designate the first principle of this or that pre-Socratic. The project of we 'Deleuzian philologists', then, is as follows:to extrapolate, on the basis of this fragment of the crown, the meaning that the pre-Socratic Deleuze attached to the notion – crucial for him, mysterious for us – of immanence.

How shall we proceed?

If we hope to understand immanence on the basis of this one text alone, we must turn, not to Deleuze, but to Spinoza and to Bergson, whose works, unlike Deleuze's, have been passed down to us in their totality. For in this text, Deleuze tells us not what immanence *is*, but *where it is to be found* – pinpointing the place where 'complete' immanence, immanence '*par excellence*', is situated. If we wish to understand this concept, it thus seems that we must turn firstly to Spinoza, the greater prince of immanence, and only secondly to Bergson, the lesser prince of immanence.

---

[5] One might think here of André Bernold's beautiful and amusing text 'Suidas' (*Philosophie* 47, Autumn 1995: 8-9).

Imagine a particular school of thought, constituting itself around this interpretative strategy – 'The Major Crown School'. This school, in truth, is going to run into a certain difficulty. If we turn to Spinoza, we will end up encountering the following aporia: we know that according to Deleuze, immanence in some way 'saturates' Spinoza's philosophy. Everything in Spinoza, Deleuze tells us, breathes immanence. But to say that immanence is everywhere in Spinoza, is to render it as difficult to perceive as a diffuse light: if it is everywhere, then it is nowhere in particular. And this is why the attempt to understand Deleuzian immanence on the basis of Spinoza will not be greatly profitable for us.

In this case, let us take a second school of interpretation, that of the 'Minor Crown', whose heuristic principle will be as follows: what is most interesting in this fragment is what it tells us about Bergson, namely that immanence is something that *happened* – once, and once only – to Bergson. If for Spinoza's philosophy immanence is a state, for Bergson's it is an event. This princely immanence which came over Bergson, did so in one text only – *Matter and Memory* – but, quite clearly, what's more, only in one part of this text: it is suggested to us that the beginning of *Matter and Memory* constitutes a 'peak of immanence' in all of Bergson's thought. Now, this makes Bergson most precious in our quest to understand what Deleuze means by immanence; for it implies that in *Matter and Memory* is to be found that which is missing in Spinoza's philosophy, *viz.*, a *differential of immanence*. Now, as physicists are well aware, to isolate or to constitute a magnitude, it is essential to have at one's disposal a variation, a difference in magnitude: to isolate the action of a force, we must have access to a variation of speed. So we can say the following: to isolate Deleuzian immanence, we must have available a variation of immanence, in the shape of a withdrawal, a reflux, of immanence. Now, it is immanence, according to Deleuze, that would ebb away after the beginning of *Matter and Memory*.

We may assume this 'beginning' to designate the first chapter of *Matter and Memory* – that is to say the theory of images, and with it the theory of pure perception. This is what seems to be suggested by the strange expression in our text: 'consciousness in principle'. This expression, in fact, quite overtly refers to the theory of pure perception – to which we shall return – a theory which, Bergson tells us, is true in principle, but not in fact – that is to say, once one ceases to think perception as undiluted with memory. We can thus say the following: to understand Deleuzian immanence, we must ask what ebbs away, what is lost, after the first chapter – and in particular, after the theory of pure perception which is at the heart of it

However, this perspective meets with a problem: if something ebbs away, from Deleuze's point of view, from Bergson's point of view nothing seems to be lost. Obviously, Bergson never wrote anything like 'immanence came to me once, but only once – and then, nevermore!' … Like every philosopher, Bergson maintained that his argument lost nothing in its development, that it approached truth more closely as it progressed. The problem, in short, is as follows: how to seize this reflux, if we know nothing of the Deleuzian sense of immanence, and if Bergson himself makes no indication of any retreat in his argument? We must distinguish a norm, a scale of measurement internal to *Matter and Memory* – a norm in light of which we would be able to register a variation. The only solution is to maintain that it is possible to diagnose the existence of a reflux, if not from Bergson's point of view, at least from the point of view of the *aspiration to be* Bergsonian. Something must be lost from a point of view immanent to the text: and thus from the point of view of a Bergsonian, if not from that of Bergson himself. So we must examine the exigencies which Bergson imposes on himself in the preface to *Matter and Memory* – exigencies which, according to him, the theory of the first chapter satisfies – and then establish how what follows in the text, beginning with the introduction of memory, fails to respond to them with the same degree of radicality. These exigencies will stand as the conditions of immanence which the first chapter satisfies to a degree unequalled by the rest of the work.

We would then find ourselves before the following possibility: we have said that Bergson holds that the theory of pure perception, true in principle, is not so in fact – for this theory does not take into account the fact that every perception is mixed with memory. If we can manage to prove that the pure and simple truth of the theory of pure perception was a *sine qua non* condition for a wholly immanent philosophy, we could then ask ourselves how such a theory could be modified so that it would be true not merely in principle, *but also in fact*.

And in this way we might stand a chance of constructing a fictional theory – one which would be neither Bergson's or Deleuze's but which, drawn entirely from Bergson, would present instructive homologies with Deleuze's theory. In effect, we would have constructed an original philosophy of princely immanence which consequently would be similar to Deleuze's in many respects, and would aid us in understanding the latter.

Now, why attempt such a construction, when we have available to us Deleuze's entire philosophical *oeuvre*, and not just sparse fragments?

For at least two reasons:

1) The first is of a general order: it is always interesting to try to understand a philosopher without interpreting them in the strict sense, but by asking whether it is possible to reconstruct them: because as partial as such a reconstruction might be, it does assure us of truly understanding what we are talking about. Given also that our understanding of Deleuze is itself, let us admit, incomplete, we might anticipate through this indirect approach the possibility of better understanding that which resists interpretation.

2) The second reason is as follows. We would like to show that the fictional system we are to work out functions as a sort of reduced model which brings to light the essential link between many aspects of Deleuze's work. It cannot be denied that this reduced model will also seem a reductive one: it will build Deleuzian 'sim-concepts' without the power to recreate the subtlety of the originals. But this simulacra of Deleuzian philosophy will perhaps have the advantage of exhibiting something – even if only a little –

of the hidden structure of the Idea. It will display, in any case, a necessary chain of decisions of thought, capable of clarifying the coherence of their model.

1. THE ANTI-KANTIAN STAKES OF *MATTER AND MEMORY*

Let us try to show how the theory of pure perception, as unveiled in the first chapter, seems to respond in a more satisfying fashion than the rest of *Matter and Memory* to Bergson's own requirements, as laid out in his 'Preface to the Seventh Edition'.[6]

It does indeed seem, in light of this preface, that a fundamental objective of *Matter and Memory* was to render Kantian critique unnecessary, and thereby to deny the need for limiting the applicability of metaphysical knowledge. This is a project one might call immanentist, precisely in so far as it is metaphysical: because metaphysics, for Bergson, means here (that is to say, at the point where metaphysics is opposed to critique): the refusal of the existence of an enigmatic thing in itself, supposedly different from the phenomenon. On the contrary, it will be a question of grasping that being is nothing that transcends the appearance – that being is more, perhaps, but not essentially other, than the appearance. The theory of the image answers to this project.

Bergson writes: '[R]ealism and Idealism both go too far [...] [I]t is a mistake to reduce matter to the representation which we have of it, a mistake also to make of it a thing able to produce in us representations, but itself of another nature than they.'[7] Matter must be considered as a set of images – and by this term, we must understand what common sense itself understands spontaneously when it conceives of matter: 'For common sense, the object exists in itself, and, on the other hand, the object is pictorial, as we perceive it: Image it is, but self-existing image.'[8] In thus maintaining that matter exists in itself just as we perceive it, Bergson explicitly undertakes to circumvent, and even to render unnecessary, Kant's Copernican revolution. Criticism is explicitly set up as the philosophical adversary that must be opposed, by neutralising the opposition to which it gives birth, that between realism and idealism – an opposition which, in turn, is indexed to the opposition between Descartes and Berkeley. Descartes 'put matter too far from us when he made it one with geometrical extension',[9] for this results in making incomprehensible the emergence within it of sensible qualities. So Berkeley was right to affirm that secondary qualities had as much objective reality as primary qualities – but his illusion was to believe that this makes it necessary to transport matter into the mind. For such a subjectivisation of matter means that it is incapable of accounting for the objective order of phenomena as ratified by the success of physics, constraining him to make such a mathematical order of phenomena the result of a divine, providential subjectivity.

---

[6] H. Bergson, *Matter and Memory*, trans. N.M. Paul and W. S. Palmer (NY: Zone, 1991), 9-16.

Kantian critique is the consequence and result of this double impasse, since it undertakes to ratify the subjectivisation of the intuited object, whilst thinking the objective order of phenomena as a condition for experience, and even for perception.

[8] *Ibid.*, 10.

[9] *Ibid.*, 11.

2. Pure Perception

How does the theory of pure perception, put forward in the first chapter, answer to Bergson's 'contra-critical' project? Let's briefly recount its essential features. The theory of pure perception is what we might call a *subtractive* theory of perception: it seeks to establish that there is less in perception than in matter – less in representation than in presentation. Returning now to images: images, Bergson tells us, act and react one upon another according to constant laws, which are laws of nature. In this ensemble of images, nothing new seems to happen except through the intermediary of certain special images, the foremost example of which is my body. For my body is an image which acts like other images, receiving and imparting movement, with this one difference: that it 'appears to choose, within certain limits, the manner in which it shall restore what it receives'. My body is thus a 'centre of action', not a producer of representations. Whence Bergson's double definition: '*I call* matter *the aggregate of images, and* perception of matter *these same images referred to the eventual action of one particular image, my body.*'[10]

What is the essential import of such a subtractive theory of perception? It appears to be as follows: if, to pass from matter to perception, we must add something, this adjunction would be properly unthinkable, and the mystery of representation would remain entirely intact. But this is not at all the case if we pass from the first to the second term by way of a diminution, and if the representation of an image were held to be less than its simple presence. Now, if living beings constitute 'centres of indetermination' in the universe, then their simple presence must be understood to presuppose the suppression of all the parts of the object that are without interest for their functions. Bergson thus supposes that living beings allow those exterior actions to which they are indifferent, to traverse them; whilst other beings, isolated, become perceptions by virtue of this isolation itself.

---

[10] *Ibid.*, 22.

Whence the relation, literally that of part to whole, that exists between conscious perception and matter. We 'might even say', writes Bergson, 'that the perception of any material point whatsoever is infinitely greater and more complete than ours.'[11] To perceive is to come to rest on the surface of images, it is to impose upon the latter a superficial becoming, far removed from the infinite profundity of material perception.

So, we perceive but a tiny part of the images which form our environment – and it is within this part that our choices operate. There are, therefore – and this point must be emphasised, since Bergson himself does not do so, and we will have need of it in what follows – there are therefore, it seems to us, *two* selections at work in the theory of perception: the 'selection of images', which gives its title to the first chapter, is both a selection made by the body, *before* the choice, and a selection proceeding from the choice made by the mind within the perceptive elements *already* selected by the body from the infinity of images. For if the mind is free, it is free in so far as it chooses, selects certain actions, from amongst the multiplicity of possible actions which it perceives in the world itself; but mind cannot choose unless an *anterior* selection, itself *unfree*, is already in operation – *viz.,* the selection of images by bodies, a selection which, this time, constitutes the *terms* of the choice.

---

[11] *Ibid.*, 38.

The body is like a continuous emission of an infinite matter whose particles constitute the terms of the choice offered to the mind. The body selects the terms, the mind chooses between the terms. There are thus three realities within perception: matter, body, mind. Communication, selection, action.

Alternatively, we could put things as follows: basically, what allows there to be bodies is finitude. Yes, the extraordinary gain of the body for Bergson is the finite; it is a massive interruption, carried out within the infinitude of communications. The body is like a windscreen for the mind against the infinite: whereas in every parcel of matter, however minute it might be, we can envisage an infinity of information, the body conquers finitude through the power of refusal. And right here is the emergence of the living being at the very heart of the inorganic: a barricade erected by a formidable power of *disinterest for that which communicates.* The living is not primarily the emergence of a power of interested choice, but the emergence of a massive disinterest in the real, to the profit of certain rare segments of the latter, which constitute the whole of perception. The body is that which discerns, in the infinity of imagistic communication, certain rare virtual actions capable of interesting action. It is only secondarily, in a second moment, when the body has made consciousness disinterested in almost all images, that the free choice of the mind can come into effect. The selection we shall call 'first', that of the body, is the following: perception as set of possible actions. The selection we shall call 'second', that of the mind, is – let us note – far less impoverishing than that of the body: the mind chooses an option at the expense of a finite number of equally possible options, whereas the body selects a finite number of options, at the expense of an infinity of images which pass through it without trace.

We say, then, that perhaps the most remarkable characteristic of the Bergsonian theory of perception – and that which makes it an anti-Kantian theory of rare radicality – is that for Bergson, perception is not a *synthesis* but an *ascesis*. Perception does not, as in Kant, submit sensible matter to a subjective form, because the link, the connection, the form, belongs wholly to matter. Perception does not connect, it disconnects. It does not inform a content but incises an order. It does not enrich matter, but on the contrary impoverishes it.

3. MEMORY-CONTRACTION

Let's return to our initial project. The perspective we have adopted is as follows: to try to show that the theory of pure perception responds better than the rest of *Matter and Memory* to the requirements of anti-Kantian immanence. To uphold this thesis, therefore, would mean demonstrating how this requirement seems to be betrayed the moment that Bergson makes of such a theory – which refuses to see any essential difference between matter and perception – a theory that is true in principle but not in fact – and this because perception is in fact always mixed with memory.

Our task is to isolate the reason why the immanentist requirement must consist in maintaining that this theory is true not only in principle but also in fact – and to try to show how such a thesis might be defended.

So, the coincidence of perception with the object perceived thus holds, according to Bergson, in principle rather than in fact. And this because the ground of real and quasi-instantaneous intuition upon which our perception rests 'is a small matter compared with all that memory adds to it'.[12] But here Bergson brings in two types of memory.

This distinction, however, does not coincide with the famous distinction of Chapter 2 between the two memories, that is to say the distinction between the habit memory inherent to the motor mechanisms of bodies, and the memory-images of properly mental memory. The distinction which interests us, and which already appears in the first chapter, is deployed within the memory put into play by the mind itself. It opposes, within mental memory, the two forms which the latter takes in its mixture with perception. These two memories might be called recall-memory and contraction-memory.

Recall-memory constitutes a complex circuit with perception, by means of which what Bergson calls in Chapter 2 'attentive perception' becomes possible. It consists in the fact that every memory-image capable of interpreting our current perception intertwines so closely with it that we can no longer discern what is perception and what memory. The example Bergson gives is that of reading, which he says is like a veritable work of divination:

---

[12] *Ibid.*, 66.

we do not simply passively perceive the signs on the page; for the mind, on the basis of various characteristic traits, fills the interval with memory-images projected onto the paper and substituted for the actual printed characters. The second type of memory which impregnates our perception is not that which impregnates the present with our memory of the past, but that which constitutes that present itself: contraction-memory. For however brief a perception might be, it always occupies a certain duration and thus necessitates an effort of memory which prolongs a plurality of moments one into the other. So that, as Bergson writes: 'memory in these two forms, covering as it does with a cloak of recollections a core of immediate perception, and also contracting a multiplicity of external moments into a single internal moment, constitutes the principal share of individual consciousness in perception, the subjective side of the knowledge of things'.[13]

The problem of the cognition of matter thus becomes the following: our perception seems (this was the decisive advance made in the first chapter) to join directly with matter in itself. In the object, we perceive the image in itself which it effectively is. Matter contains no depths, no hidden aspect. In this sense, Bergson's immanentism held fast to the fact that matter is given wholly as that which it is: no space being left for a thing in itself inaccessible to cognition, a hidden transcendence. And, what's more, the world was not immanent *to* consciousness, it was not a transcendence-in-immanence like Husserlian objectivity.

On the contrary, it was consciousness that slid over the surface of matter in itself, the latter being identical to what common sense believes it is in grasping it. But in introducing memory, Bergson seems to distance himself strongly from such common sense. For from that point on, matter becomes what remains of perception once one has retracted that which memory, in its two forms, continually introduces into it.

---

[13] *Ibid.*, 34.

Now, it appears to us that this correction irremediably compromises Bergson's immanentism, and this, not because of the introduction of memory-recall, but rather that of memory-contraction. Memory-recall, in fact, does not obliterate the possibility of an intuition of matter in itself. We can, by according sufficient attention to the perceived object, make it so that the stereotypes of the past will not cover over the singularity of the real thing. This is, for example, what we do when proof-reading a text: we force ourselves to read the words as they are written, and not as we know they are written. An effort of concentration thus suffices, in principle, to extirpate the veil that memory-recall throws over present perception, so as to liberate matter from the mechanisms of recognition. The immanentism of pure perception is thus unaffected by the addition of memory-recall. But the same is not true, we would suggest, of memory-contraction. To see why, we must first give a more precise account of what this second form of memory consists in, and above all, what the operation of extraction consists in, whereby this memory is removed from the perception with which it is supposedly mixed. The essential characteristics of this second form of memory are described in the fourth and last chapter of *Matter and Memory*.

Contracting memory originates in the Bergsonian theory of the rhythm of durations. Bergson will introduce this rhythm with a significant and still celebrated example: that of the vibration of light. In the space of a second, he writes, red light accomplishes 400 trillion vibrations – in other words an immense number of events, which it would take us no less than 25,000 years to enumerate, were each vibration to last long enough to impinge upon our consciousness. So we carry out an incredible contraction of material reality when we perceive in one moment what includes within itself an immense number of events. Now, it is this work of contraction that gives rise to qualities. According to Bergson, the heterogeneity of qualities is due to the contraction of homogeneous – and in virtue of this fact, quantifiable – vibrations, from which matter is composed.

Let's cite the crucial passage :

> May we not conceive that [...] the irreducibility of two perceived colours is due mainly to the narrow duration into which are contracted the billions of vibrations which they execute in one of our moments? If we could stretch out this duration, that is to say, live it at a slower rhythm, should we not, as the rhythm slowed down, see these colours pale and lengthen into successive impressions, still coloured, no doubt, but nearer and nearer to coincidence with pure vibrations? In cases where the rhythm of the movement is slow enough to tally with the habits of our consciousness – as in the case of the deep notes of the musical scale, for instance – do we not feel that the quality perceived analyses itself into repeated and successive vibrations, bound together by an internal continuity?[14]

In other words, what matter is in itself can be grasped again through a certain thought-experiment, whether or not we admit the idea of a variability of rhythms of duration, of a degree of tension as Bergson calls it, which makes us comprise under the form of distinct qualities an immense number of events which, for matter, represent so many moments in which the qualities are strung out. The slower the rhythm is, the more distinct the material events, and the more diluted the qualities, once the latter become noticeably dispersed in the course of temporal succession. The notion of rhythm thus gives us to apprehend what we might call a 'concrete scale of temporalities'. We only live at one scale of matter – immensely vaster than that of the atom, and immensely less vast than that of galaxies. We thus occupy a scale of durations, a particular rhythm of the current of time, which renders us unconscious of all events below two millionths of a second, whereas such a duration is sufficient for luminous matter to produce millions of vibrations, that is to say millions of distinct events.

---

[14] *Ibid.*, 203.

4. Critique of Memory-Contraction.

We will call 'detension'[15] the operation through which Bergson 'decontracts' the qualitative product of memory, so as to decant material perception from its mnemonic and subjective envelope – and this to rediscover matter such as it is in itself, rather than for us. Let us try to explain, then, what seems to us to pose a problem in this theory of detension, all the while attempting to give a Bergsonian dynamic to our dissatisfaction.

---

[15] Obviously, in a different sense to that which Bergson gives to this term when he uses it in chapter 3 of *Creative Evolution* (trans. A. Mitchell, NY: Dover, 1998), to designate the engendering of space by duration, at the moment where the latter attains the limits of its creative *élan*.

We know how Bergson criticises the thesis according to which there would be only a difference of degree between perception and memory, that is to say the empiricist thesis according to which memory would be only an attenuated perception: if this was the case, he remarks, we would also have to maintain the inverse proposition – that is, that an intense memory could not be distinguished from a weak perception – an inversion which suffices to demonstrate the incoherence of the thesis. This being the case, we will express in a similar fashion our doubts concerning the operation of detension: if the slowing of the rhythm of duration is equivalent to dilution, or to a 'stringing-out', as Bergson says, of qualities, then we must also maintain the inverse, that *every experience of the dilution of colours or of the movement of sound towards the bass is equivalent to the experience of a slowing of time*. Or further, if one maintains that material duration makes colours paler and sonorities deeper, one must then also maintain that every perception of a pale colour or of a low sound makes us change in our rhythm of duration. But this is evidently not the case, since on the contrary we enjoy a capacity to traverse the palette of the painter or the scale of the piano without at all modifying our vital rhythm, since the low notes do not modify the rhythmic exigencies of the score or of the metronome. The rhythm of duration and the tonality of the scale are thus indifferent one to the other: not only because the lowest notes can be played in a more rapid rhythm than the highest, but also because time can pass quicker whilst I listen to a certain low sequence that I particularly like, whereas time might seem to drag listening to a high sequence that I do not enjoy.

On this basis, it seems that I cannot carry out a real detension of perception, in order to disentangle matter in itself from subjective memory. Examining the question more closely, it might be said that the difficulty in disentangling perception from memory-contraction comes from the fact that the latter is supposed to constitute the very qualities of perception – which is not the case with memory-recall. Whereas in the case of the latter, I can make the concrete experiment of the dissociation of memory and perception – the experience of attentive reading – here this is no longer possible. In fact, I find myself face to face with the following aporetic alternative: either I try to intuit the result of detension directly – but in that case I would be led back to the experience of *my own* duration, and not that of material duration, the experience of colours which pale or of sounds which become lower. Or I return to science, distinguishing the vibratory and homogeneous nature of matter – but in this case I content myself with registering the result of an experiment, rather than thinking the supposedly continuous nature of homogeneous matter and of heterogeneous perception. In the latter case, therefore, I accede to the vibratory nature of matter, but only by way of a science which is discontinuous with my concrete perception of qualities.

In other words, memory-contraction seems to abolish the principal result of the theory of pure perception, namely that of the cognisability of the in-itself. For matter appears to us as that which has not been made the object of the work of contraction. But since this contraction has always already taken place, since its effect is supposed to reach the elementary components of perception, we cannot see any convincing way to take the *reverse path*, so as to rediscover matter in itself not yet affected by our subjective duration. In yet other words, the vice of contracting-memory seems to be that it plunges us once again, from a theory of perception-ascesis – a profoundly original moment of the Bergsonian conception, a moment also when his anti-criticism is at its most radical – into a theory of perception-synthesis, one which by virtue of this fact is subject to the Kantian separation of the for-us and the in-itself. For the force of the ascetic theory of perception consisted in the fact that the form of matter was posited in matter itself: synthesis was material, and consisted in the regulated relations that the images maintained one with another; representation added no sort of synthesis to matter. But everything changes with the contracting theory of memory; for now perception once again introduces a form into matter itself, a synthesis – specifically, a temporal compression – which is hailed as the genesis of immediate qualities. But if perception is synthetic, then we are truly condemned never to discover the nature of the matter so synthesised, since we are trapped within the limits of such a synthesis. This is result of the experiment we have made of our incapacity to intuit a detension which takes us outside the qualitative world proper to our intimate duration.

To better grasp the difficulty, we might invoke Kant's *Anticipations of Perception*. We know that, in the first *Critique*'s *Analytic of Principles*, Kant maintains that we can anticipate not only the form of the phenomena, but also, to a certain extent, its matter – and this by affirming that every reality admits of a degree, that is to say an intensive quantity, not divisible into units but into differentials. We know in fact that time is divisible to infinity, and that consequently between a degree *x* of a given quality, a degree supposed conscious, and the degree 0 of consciousness, are ranged an infinity of moments in time, which are the object of syntheses that are not yet conscious. Thus, the immediately apparent qualities of perception have in fact already been informed by consciousness. Perception is the sum – or, better, the integral – of differentials which alone can be identified with the thing in itself. But to rediscover this thing in itself such as it is, we must have at our disposal an operation of derivation that we would be sure would correspond to the exact inverse of the pre-conscious integration of perception. Now, it is this which we cannot determine with any certainty in any case. In this sense, Bergson appears to founder upon a difficulty which, apart from some obvious differences, recalls that which contributes to Salomon Maïmon's justification of his scepticism: for Maïmon, in his *Essay on Transcendental Philosophy*, having precisely identified the noumena with the differential of consciousness, and the phenomena with its integration by the productive imagination, proscribed himself from operating the reverse path through the understanding – the path that would go from the phenomena to the noumena. According to him, the noumena must remain unknown to us, because we could never be sure that the derivation proposed by the philosopher to rediscover the noumena would be the exact symmetrical counterpart of the integration within consciousness of such a noumena.[16]

In short, it seems to us that all the anti-Kantian and immanentist gains of perception-ascesis are put at risk by

---

[16] For a more detailed examination of this aspect of the *Essay on Transcendental Philosophy* see J. Rivelaygue, *Leçons de métaphysique allemande*, vol.I (Paris: Grasset, 1990), 134-149.

Bergson's return to the circle of subjective synthesis. As soon as Bergson introduces the work of synthesis into subjectivity, he brings back the possibility of a thing in itself inaccessible to thought – and thus the possibility of a radical transcendence. The stakes of the discussion thus become as follows: can one envisage a theory of perception-ascesis which avoids passing via the synthetic moment of contraction? What would such a theory look like, and how might one try to justify it?

5. THE RETURN TO PURE PERCEPTION

How to think pure perception without contracting-memory? Let us return to the rationale which seemed to lead Bergson to introduce the idea of contraction. This rationale, if we reflect upon it, seems to be reducible to one fact: *viz.*, that the science of elementary matter decomposes minimal conscious durations into extraordinarily rapid events – specifically, the vibrations of light. It is such a vibratory reality of matter that the theory of contracting memory seeks to account for, by pinpointing the process by which this material state is transformed for us into distinct qualities. But is there anything in this fact that a theory of the image alone could not account for? It seems that the difficulty comes from the fact that an image – that of a perception or colour – is supposed to contain many other images – those of 'vibrathomogenes'. Now if an image was to present to us matter such as it is in itself, must not its prodigious vibration also appear to us? Since this is not the case, we must indeed admit that our grasping of the world introduces an operation which modifies it.

However, Bergson himself gives us the means to respond easily to this objection: has he not told us that the theory of the image supposed that there were many more things in matter than in representation? Did he not found his immanentism on the fact that matter is *not other, but more* than representation? This being accepted, what prevents us from attributing to matter all the images that we can extract from it? For if matter is a set of picturesque images, there is nothing to stop us saying that it is also, in addition, a set of images in which qualities no longer have any place: nothing stops us from making of matter all the images which we might have at every scale of time, and indeed of space. This, let us repeat, was the very force of the subtractive theory of pure perception: the thing in itself is all the points of view it is possible to take on that thing: from the most intimate, those of its tiniest details, to the most remote. In that case, why not say the same of luminous matter, and hold that light is *all* the images that can be taken from it: the colours of the spectrum, as well as homogeneous vibrations? Nothing prevents us from according to the matter-image these two points of view: maintaining that it is heterogenous and homogeneous *as well*, both image-perception *and* experimental image, coloured image *and* vibratory image. This amounts simply to saying of matter that it is composed of radically distinct images according to its temporal and spatial scales. In other words, it amounts to according to matter all the rhythms of duration, and to making of human perception not the *contraction* of material quantity, but the *selection* of one of the rhythms of a matter-image which contains each and every one of them.

6. The Subtractive Model

From this point on, we can start to examine what the purely subtractive model drawn from *Matter and Memory* would consist in – a model of subtractions without contractions.

Here are the two postulates from which we begin:

1) Matter is composed of images. These images all communicate one with another, according to laws that we identify with the laws of nature. This communication we will name with the term *flux* – the flux by which images receive and transmit movement to images. Matter thus consists in a multiplicity at once qualitative and quantitative, picturesque and homogeneous.

We can then agree on the following terminology: we will call *heterogeneous* a multiplicity that is not simply qualitative, but at once qualitative and quantitative. If the homogeneous remains identifiable with quantity, the heterogeneous ceases to be identifiable with quality. The heterogeneous is more heterogeneous than quality, comprising not only the differences of qualities between themselves, but also the differences of quantities between themselves, and the difference of quality in general from quantity.

2) To these images, connected to each other by flows, we must add *interceptions*, cuts, which from the point of view of images mean nothing more than a local isolation – their becoming-superficial. Here, we distance ourselves, for reasons of clarity, from Bergson's theory taken strictly: rather than saying that the rarefaction of images in perception is due to the fact that the living being allows itself to be traversed by most images only to retain a few of

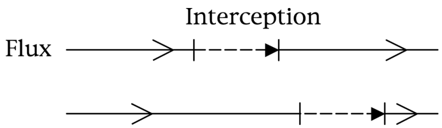
them, we say that this rarefaction is due to cuts, barrings, which only permit certain flows to penetrate into consciousness. The essential remains: perception is in every way still thought as a rarefaction of matter.

We can formulate these two postulates more precisely by including both in the following proposition: *there is becoming, and becoming is fluxes and their interceptions.* This statement allows us to say the following: a flux is not sufficient to constitute a becoming – for this, there must also be interception. Fluxes, certainly, transmit movement: but this movement is not a becoming, in the sense that, ruled by the laws of nature, it connects every image to every other image, according to a necessity which saturates the real in some way. Every thing being connected to every other according to laws, the cognition of an image is sufficient in principle for us to determine the present, past and future movement of all the others – and this to such a point that the very difference between the three dimensions of time is erased, to the profit of an immutable web of transmissions of movements. One is faced with an immobility made of movements, analogous to that of a powerful jet of water, in which the continuous movement of matter gives rise to a continuous immobility of form. Flows, left to themselves, are just such a pure mobility, immobilising themselves by the very fact that no obstacle obstructs their deployment: they are the bonds between all things ruled by fixed laws.

For there to be becoming, something must happen, and for something to happen, it is not enough that something comes to pass – on the contrary, it must be the case that something does not pass: there must be a disconnection. This is the only way to introduce a becoming into matter, without introducing anything other than matter: it is the only way for us to uphold Deleuze's 'magical formula: PLURALISM = MONISM',[17] without its leading us back to dualism. The monism of heterogeneous matter will accommodate within itself the pluralism of eventality, without for all that accommodating anything other than matter – that is, without introducing ontological duality.

Let us see how such an operation is possible. The condition of there being a becoming is that a change is produced which cannot be reduced to a material flux. This imposes the following thesis upon us: there must exist a becoming of interceptions themselves. It must be that the interceptions change. But how is such a change thinkable? In view of what we have said above, this can only happen in one way: *the interceptions of flux must move along the lines of flux.*

So we obtain schema 1:



Schema 1: Interceptions of flux and flux of interceptions.

We can see here that a becoming is always two becomings – for there to be becoming, becoming must become twice: as flux of images, and as flux of interception of images. Becoming is thus composed of a double 'arrowing', which, however, introduces no ontological dualism. The first arrow is that of flux. Only the second arrow introduces becoming. Through this double arrowing, then, one can achieve *the grafting of the Bergsonian theme of the image onto the Stoic theme of incorporeals*, as mobilised by Deleuze in *Logic of Sense*.[18] We shall thus dub the temporal dimension of flux *Chronos*, and the temporal dimension of interceptions, *Aiôn*. What authorises us to adopt, not only the Stoic language, but also the Deleuzian terminology as it is put to work in *Logic of Sense*? Two things:

---

[17] *A Thousand Plateaus*, 20.

1) Firstly, we know that the division between *Aiôn* and *Chronos* in *Logic of Sense* distinguishes the temporality of deep causes, the temporality of corporeal mixtures, from that of incorporeal events. Now, it is indeed to this type of division that the preceding double arrowing corresponds: fluxes are indeed dynamic mixtures of matter, and the interceptions are indeed incorporeals, since they are nothing material. In addition, the becoming of interceptions is a becoming which rises to the surface from the depths of images, since the result of the interception is the becoming-superficial of matter: its reduction to its envelopment in perception. So that we can legitimately take up Deleuze's exclamation with regard to incorporeals: '*Everything now returns to the surface*'.[19]

2) Secondly, we can attribute to *Aiôn*, thus redefined as displacement of cuts, a property homologous to that of the Deleuzian *Aiôn*: namely *eventality*, understood as a unique Event in which all events communicate, 'the affirmation of all chance in a single moment', the 'unique cast for all

---

[18] *Logic of Sense*, 'First Series of Paradoxes of Pure Becoming', 3-6.

[19] *Ibid.*, 10.

dicethrows'.[20] In fact, in order to think the process whereby the interceptions are displaced, the temporality in which the interceptions change, we must exclude every form of material explanation.

If the displacement of a disconnection proceeds from material laws, it will be reduced to a flux like any other – and no becoming would exist. But if there is becoming, no physical law can account for it. Neither determinism, nor probability – the double explicative paradigm of material processes – can therefore be mobilised to account for the displacement of incorporeals. So if we wish to say something positive with regard to such a becoming of breaks, it falls to us to posit that this becoming certainly constitutes a chance occurrence, but one which is non-probabilisable, since it is the result of a unique throw of the dice, launched from all eternity upon the immutable table of fluxes.[21]

Let us attempt, then, to indicate more precisely the meaning of *Aiôn* so understood as the displacement of disconnections. Firstly, we must return to the being of disconnections. We said above that one thing at stake in the subtractive model was the avoidance of every form of dualism, or of differentiation between modes of being. Disconnected-being cannot therefore be anything other than flux-being. Now, in order to maintain this, it is not enough to say that disconnected-being is nothing: for to say this would be to lead ourselves back to a Epicurean–style dualism – that is to say, a dualism of matter and void.

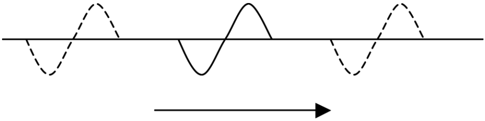
---

[20] *Ibid.*, 205.

[21] On Deleuzian chance, understood as unique dice-throw and eternal return, see Alain Badiou's commentary in *Deleuze: The Clamor of Being* (trans. L. Burchill, Minneapolis: Minnesota University Press, 2000), 'Eternal return and chance', 67-78.

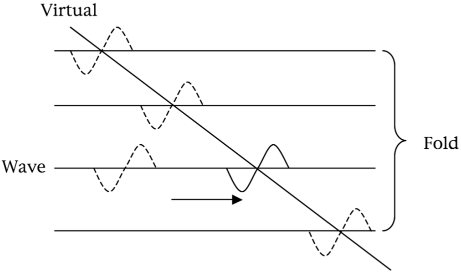
The 'ontological landscape' furnished by our model in fact resembles an 'inverse Epicureanism': not one of real atoms displacing each other in a hazardous fashion (precipitated by the *clinamen*) in an infinite void, but one of 'atoms of void' displacing each other in a hazardous fashion within the infinite plenitude of fluxes. It must therefore be that disconnection itself is ultimately reduced to the plenitude of heterogeneous flux. But how to think a break of flux, which is itself a flux, without annulling it as break? Very simply, by reducing the break to a *detour* of flux, accompanied at the same time by a *retardation effect* imposed upon this same flux. It suffices to multiply the detour to infinity to obtain a retardation itself as durable as desired. A break is a local accumulation to the *n*th power of detours of flux. We therefore find ourselves within a strictly continuist ontology, which produces 0 on the basis of an infinite summation of 1 – or which produces nothing on the basis of a infinite summation of the real.

In identifying break with detour, we assure ourselves that nothing exists apart from matter. But it remains true that, if there is becoming, we must maintain the distinction between *Chronos* and *Aiôn*. Why? Becoming, as we have said, depends on the becoming of breaks – and therefore on the becoming of detours. The becoming of a detour is its displacement on a line of flux. But how, or under what conditions, can such a displacement be thought? Under one simple condition: *we must have a past.* Now, *Chronos* tells us nothing about the past of a break. This can be seen quite easily in the following schema:



Schema 2: The wave.

If a detour had a material past, it would then be reduced to a *wave* – the wave whose displacement is shown in the schema. In the most general sense we understand by 'wave' a material movement whose past as well as its future can in principle be reconstructed, in a deterministic or probabilistic way. To be pregnant with its past, if one might so speak, as well as with its future – to detain one and the other, enveloped in its actual-being – this is what is proper to the wave. Now, the detour is not materially distinct from the wave – since it itself is made of matter only – but its displacement must be, since its temporality is hazardous. We must therefore sketch a *second line of the past*, alone capable of distinguishing these two indiscernibles, the wave and the interception. We therefore have the following schema:



Schema 3: The Virtual.

This second line of the past, which is no longer that

of the wave, I name *the virtual*. We can fix the vocabulary, then: a detour possessing a material past will be said to be a wave; a detour proceeding from the line of the virtual will be said to be *a fold*. Without entering into detail, we can see clearly that the virtual thus characterised has many decisive points in common with the Deleuzian virtual:
– The virtual is not indeterminate, but entirely determined;
– The virtual is real – if not, there could be no becoming of the fold – the virtual is thus opposed to the actual, but not to the real;
– The virtual is not, like the possible, the phantasmatic double of the actual – identical to the actual but minus existence – rather, the virtual and the actual have no reason to resemble each other;
– Finally, the virtual is the ontological condition of authentic becoming, that is to say of the unforeseeable creation of novelty.[22]

But it will perhaps be argued that this introduction of the theme of the virtual into the interceptive model is of no interest. All we have done is to inject into our model the Bergsonian virtual, inherent to the conception of duration as unforeseeable creation; and by this fact, and for all that the virtual undoubtedly represents the essential Bergsonism heritage in Deleuze's thinking, the model proposed will only be as homologous with Deleuze as Bergson is. All of which is certainly correct. But what makes the introduction of the virtual into the subtractive model interesting is that it means we have to modify, on an essential point, the Bergsonian notion of the virtual. The modification might be formulated thus: *we are led to think the virtual independently of the couplet quantity-quality*. Now, this couplet, in Bergson, constitutes a primordial polarity for the thinking of pure duration. In the *Essay on the Immediate Data of Consciousness*,[23] for example, pure duration is qualitative multiplicity, as opposed to an homogeneous and quantitative matter which by virtue of this has no duration. Whereas in *Matter and Memory*, as we have seen, quality and quantity are now thought in continuity with each other – but it is precisely memory's role to obtain quality via the contraction of quantity.

---

[22] On these aspects of the virtual, see in particular: 'The Actual and the Virtual' in *Dialogues II*, 112-5; and A. Badiou, *Deleuze, op.cit.:* 'The Virtual', 43-64.

On the other hand, in the subtractive model, this polarity becomes inadequate for thinking the virtual, and this for the simple reason that the fluxes are already both wholly qualitative and wholly quantitative. More particularly, quality ceases to be in itself the mark of novelty. Which implies that the language of unforeseeable creation will not be primordially a language of quality, but a language of *folding* – of the fold's becoming-virtual: a language which would be, ultimately, a topology, or rather a *geology* of the virtual. Through this we do indeed engender an effect of homology with Deleuze: namely a Bergsonian heritage of the virtual, expressed in geological rather than qualitative terms:[24] to say that 'there is becoming' is to say that 'there are virtual folds', or that 'there is folding'.

---

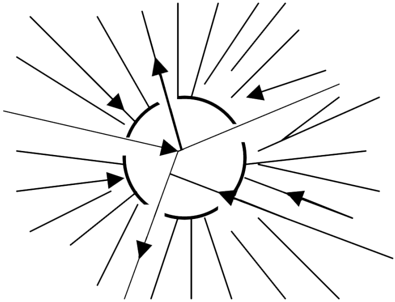
[23] Translated by F.L.Pogson as *Time and Free Will* (London: Allen & Unwin, 1950).

[24] One thinks here of two texts of Deleuze's: *The Fold*; and, in *A Thousand Plateaus*, '10,000BC: The Geology of Morals' (39-74).

To progress further along the path of a reconstruction of Deleuzian thought via the beginning of *Matter and Memory*, we must now emphasise the following point: we began knowingly from a theory which is not exactly that of pure perception, but which is somewhat less rich. Because not only did we divide *Matter and Memory*, making the first chapter autonomous, but we also divided the theory of pure perception itself. Let us explain. In the theory of pure perception, Bergson gives himself an indeterminate centre of action, that is to say a free being: it is such a freedom that is at the origin of the selection, amongst images, of those alone which interest the living being. Now, the refusal of all dualism constrains us, for our part, not to accord existence to beings endowed with freedom. For we would then have two types of being, free beings and beings subject to material laws. If Deleuze sees an immanentism in pure perception, it is no doubt because he divines a monism beneath the apparent dualism of freedom and matter. To extract this monism, it must be shown that what Bergson calls freedom can be obtained as a particular case of subtractive becoming. In other words, it must be shown in what way the living being is a particular case of such a becoming.

Let us reformulate things more clearly. It must indeed be seen that in admitting of fluxes and interceptions, we have not yet admitted of any living being, nor *a fortiori* any free being. An interception, even a sum of interceptions, do not make a living being. For what is a living being, according to the Bergsonian inspiration? It is a *local rarefaction* of fluxes: because a living being is a body – that is to say, a *selection* – but a selection that we have named as *primary*: a selection anterior to all free choice, and one which offers us the terms from which a freedom might potentially be chosen. In other words, a living being is a *place* where fluxes can no longer pass through fully and indiscriminately. Consequently, we can advance the following definition of the living being: *a living being is a discontinuous loop of interceptions.* A loop, because it is necessary to assure a place for the rarefaction of fluxes; a discontinuous loop, because a living being cannot entirely cut itself off from the fluxes – otherwise it would no longer have any affective and/or perceptive relation with the surrounding world. I mean by 'rarefaction' any localised impoverishment of fluxes – thus, every living being is a rarefaction. A rarefaction is more than an interception: an interception does not make a rarefaction, whereas a rarefaction is made solely from interceptions of fluxes.

We obtain schema 4, the schema of the living being or the body :



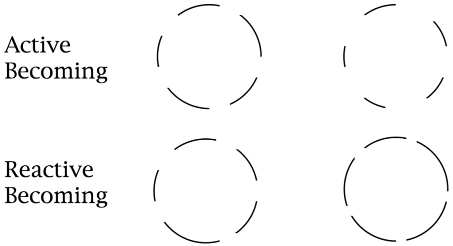
Schema 4: The Body

But we might then pose a new question, *viz.*: Is there a becoming of living beings? Or again: Is there an evental becoming of rarefactions? If we suppose it possible to think the living being, then there *must* be such a becoming. For if there was no becoming of rarefactions, one could only consider what a living being was made of, the matter that constituted its site. One could think what it is made of, but not what it is: one could think it as organism, but not as rarefaction. One could think the material substance of bodies, but not the bodies themselves as site of rarefaction, of the selection of images. But how to think the non-organic living being, since rarefaction itself is not made from nothing – since there does not exist any vital fluid, any matter other than that of physics, which would render singular the mode of being of a living being? One solution to this difficulty is the following: thinking the living being must come down to thinking the *becoming* of zones of rarefaction. There must exist a non-organic past of bodies – there must exist virtual rarefactions. We need a non-organic past of the living being, an inorganic becoming of bodies. Or further, we need a *body without organs*.[25] Then, if the foldings remain sufficiently coherent to constitute the foldings of rarefactions, we would be able to think life on the basis of its own evolution, and thus isolate a *typology* of vital becomings, becomings which cannot be identified with organic fluxes.

If we entrust to science the care of describing and thinking the states of things, that is to say the states of flux – we will reserve for philosophy the task of describing and thinking virtual becomings. Let us call *evaluation* every typology of becomings that are vital, but inorganic. What typology will be adopted by our evaluation? What are the major types of vital becomings admitted by the living being understood as discontinuous loop of interception? Two elementary cases present themselves: that of the narrowing and that of the broadening of discontinuities. The first *increases the power of disinterest* of the living being, the second signals itself through an *increased openness* to a part of the fluxes. We will call the second becoming *active*, the first *reactive*.

---

[25] On the Body without Organs, see *Anti-Oedipus*.



Schema 5: Active becoming, reactive becoming.

But before going further, it is time to show precisely in what way the interceptive model is distinct from that of pure perception according to Bergson – and why this distinction should interest us. The distinction is the following: Bergson begins with the postulate that there exist beings capable of acting freely – that is to say, centres of selection of images, the supposed selection being a selection of the *second type* (that which designates a *free choice* between various options). From this he then infers the nature of perception, which turns out to be a selection of the first type: an *unfree* selection from the terms of the choice. We have proceeded in the other direction: we gave ourselves *only* the first selections – unfree selections, that is – and then constituted the living being as a particular configuration of those first selections. Thereby, only part of the theory of pure perception is adopted:

because only one type of selection is introduced into the constructed model: unfree selection. These selections are then endowed with an unforeseeable becoming, alone capable of producing a novelty, thus making possible a distinction between two regimes of selection – active and reactive. We therefore understand that the advantage of the subtractive model is to allow *the grafting of Bergsonian selection onto Nietzschean selection.* For having removed from the Bergsonian model the notion of freewill recused by Nietzsche, we can bring together the two senses – the Nietzschean and the Bergsonian – of the term 'selection': that which designates the selection of images by perception, and that which designates the typology of vital becomings. A new effect of homology with Deleuze: the subtractive model allows us to think the meaning of his predilection for two philosophers who seem prima facie so very dissimilar. But in order to obtain this rapprochement rigorously, we must construct the concept of the active more precisely.

What is a reactive becoming, according to the present model? It is a becoming which manifests itself through a disinterested retreat inherent to the very constitution of the living being. This disinterest, precisely in so far as it is given as constitutive of the essence of the living being, we will give the name of *stupidity* [*bêtise*]. Stupidity, the stubborn stupidity of the proverbial mule, is for the living being always a way of conserving itself in its being, without opening out onto exteriority. On the contrary, an active becoming is always manifested through the fact that something *happens* – and more precisely, something *interesting.* So the categories of interesting and uninteresting are, for us, substituted for those of freedom and unfreedom. For the two becomings

– active and reactive (or stupid) – are both anterior to all free choice: they affect the space of choice, anterior to any choice being made. This is why becoming – and particularly active becoming – must be thought as essentially *passive*; must be thought, even, as an increase of the passivity of the living being, of its 'passability', a way for it to register an increased affectivity to a number of external fluxes. This increase is not itself material, since it is a folding: but it is a becoming which makes an increased flux of matter pass into the body. The concepts of encounter, of passivity, and even of affect – concepts resonant with the Deleuzian thinking of the event – thus take on a vital, not merely organic, significance here. To the active body, capable of an innovative, inventive becoming, something always happens: its increase of force does not come from an autonomous decision of a constitutive subject, but from an experience that is always undergone, an affective test in which a radical exteriority gives itself, an exteriority never before felt as such.[26]

By way of a conclusion, let us now come to that which seems to us to be the principal interest of the subtractive model.

The model allows us to give a precise response to a question that might suggest itself as regards the notion of life in Deleuze, and also in Nietzsche – a question which, we believe, already traverses the work of these two philosophers: how does the living being succumb to reactivity? A question that one might equally formulate as Deleuze does in *Anti-Oedipus*: are all forces doomed to become reactive?

---

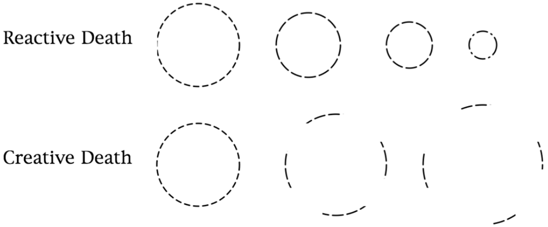
[26] On thought and its relation to stupidity, see particularly Chapter 3 of *Difference and Repetition*, and also François Zourabichvili's analysis in *Deleuze. Une philosophie de l'événement*, (Paris: PUF, 1994; republished in 2004 with a new introduction), 24-33.

That a vital becoming should be active is not difficult to understand: whether or not one agrees that a being tends to persevere in its being, it is easy to grasp that the living being tends to extend the surface of its relation to the world. But that a being should diminish its power, and thus diminish its receptivity – its inventive passibility – is obviously an enigma. It is an enigma that is reinforced when we consider that a reactive being can propagate its reactivity to other bodies, separate the active from what it can do, and that reactivity even seems ultimately to affect those experiences which in themselves are the most innovative, the most revolutionary. Indeed, the question is also that of dualism : because if we cannot manage to grasp in what way life is virtually reactive, we risk ending up with a separation between two modes of being whose communication will be averred unthinkable, even whilst it is, on the contrary, quite manifest. In short, how to understand that life should be complicit with reactivity ?

The subtractive model gives a precise response to this question. And this, for a simple reason: such a model leads us to maintain that there exist two types of death. *And it is because there are two types of deaths that there are two types of lives.*

Let us explain, and conclude.

Note firstly that we do indeed discover, in our model, an essential ambiguity of death. Because two deaths appear to be conceivable for inorganic bodies, two ways of 'erasing' the discontinuous loops: either by a *closing in*, and a progressive ossification of the loop of interception, or by *dissipation* and progressive disappearance of the loop itself. Or again: either a death by diminution of the surface of the loop (ossification of bodies), or a death by diminution of the loop (dissipation of bodies). This is what the following schema shows more clearly:



Schema 6: Reactive death, creative death.

We could say that death by diminution of the surface of the loop is equivalent to a monadological death, a death by vanishing: folded in upon itself, the body shrinks more and more, until completely annihilated. The *reactive* power of death might well be conceived in this way: for the reactive tends toward a death by narcosis, by exhaustion, by an ever-increasing indifference to the world. And we could name as the *priest* the conceptual persona heralding such a regime of death.

But how to think this other possibility of death, by diminution of the loop, by dissipation of the body, by an ever-wider opening of the latter onto the external flux, up to a complete dissolution? And what conceptual persona, this time, will incarnate such a deadly becoming?

It seems to us that it is the possibility of this second death that *affectively* dominated our very first reading of the beginning of *Matter and Memory*: reading this text, so gripping in many ways, we felt, however, at the same time, a vague terror. And this impression of terror was due to the following: as a good materialist, we had always considered death as a return of the body to inorganic matter – thus, for the subject, as a simple nothing. But if matter is what Bergson says it is, then death – the return to the material state – would not at all be identified with nothing, but rather with madness – and even an *infinite madness*. For becoming-material would be the effacement of the selection of images. And it would seem then that to make an image of death, we would have to conceive what our life would be if all the movements of the earth, all the noises of the earth, all the smells, the tastes, all the light – of the earth and of elsewhere, came to us in a moment, in an instant – like an atrocious screaming tumult of all things, traversing us continually and instantaneously. As if the nothing of death could not be understood as a simple void, but on the contrary only as a saturation, an abominable superfluity of existence. Death, thus understood, is the triumphant reign of communication. To die is to become a pure point of passage, a pure centre of communication of all things with all things. It will be seen, then, that the living being is not the emergence of pain in an atrophied world, but on the contrary the diminution of madness in a becoming-terror of chaos, bringing the latter to an infinite speed. Of this death-madness, this death-terror, one might say something like that which Deleuze says of chaos, in the conclusion to *What is Philosophy*?:

> We require just a little order to protect us from chaos. Nothing is more distressing than a thought that escapes itself, than ideas that fly off, that disappear hardly formed, already

> eroded by forgetfulness or precipitated into others that we no longer master.[27]

The deadly becoming of communication thus brings with it an important difference from the reactive death of the priest: the fact that it *resembles active-becoming*, and is even, up to a certain point, indiscernible from the latter. As if the sciences of communication – advertising, marketing, etc. – which, Deleuze says (also in *What is Philosophy*?), have arrogated the concept to themselves – as if these disciplines were the terrifying continuation of authentic creation in the inconsistent and insignificant tumult of information.[28]

In the subtractive system, then, the *communicator* must be made an original conceptual persona, alongside the priest: he who founds becomings which are no longer reactive, but *creative* – becomings which decant death at the very heart of creation, by apparently marrying it with movement, and with words. Becomings which are not those of a stupidity closed in on itself, but which are rather those of a certain obstinate silliness, of a frenetic openness to whatever appearances of novelty come along. The terror of the philosopher before philosophies of communication, or at least certain of their avatars – the way the philosopher flees, as Deleuze says, as soon as they propose a 'discussion' – would be a terror before his own possible death – that which he courts dangerously: death-madness, death-inconsistency, and not death-narcosis. Degradation in the uninterrupted flood of communication, and not somnolence in the reinforced mutilation of affects.

---

[27] *What is Philosophy?*, 201.

[28] *Ibid*., 10

We can see here, in passing, a second anti-Kantian characteristic of the subtractive model: not only does one attain the in-itself via a perception-ascesis, but what's more, that towards which the philosopher invites us to incline cannot be thought as Idea, even as regulative Idea. And this for a very simple reason: in this model, *there could be nothing worse than to achieve that towards which we tend*. One tends towards chaos when one invents, when one creates, but there is nothing one intends less than actually catching up with it. It is at once a tendential and an anti-regulative model: we must continually approach the chaos which governs the propensity to create, and continually guard against falling into it.

And so finally we clearly understand the source of the priest's power, that is to say the origin of the seductive force of the reactive over the living being: this seduction comes from the fact that the priest can at least promise us *a nice easy death*, a death that reinforces infinitely the process of birth, which was already originally a process of disinterest with regard to flux. The priest promises us a second birth, a birth that is an isolation, an indifference raised to the second power against the external world, a rarefaction greater than that of coming into the world – in short, a sort of immortality, after its own fashion. The model of the two deaths thus permits us, without founding any dualism, to understand the complicity of life with reactivity: *becoming-reactive is what defends life against its becoming-creative* – or more precisely: narcosis-becoming stops us from becoming-mad. For this is the great seduction of reactivity: which philosopher, faced with a communicator, wouldn't silently wish to become a priest?

In short, we have two deaths, one of which is worse than the other – and this is indeed why to think with Deleuze – really to think – is something as rare as it is difficult: because to think is to become a neighbour to the worst of the two, and to risk the becoming-chaos of life, its infinite becoming-creative. To think is twice victorious to cross the Acheron: it is to visit the dead, or rather death, and above all to succeed in returning; to remain a structured living being, having tested oneself against the nascent destructuration of new fluxes; to maintain oneself in the Outside, but to hold oneself close, thus to some degree closed, and thus to discipline into writing a chaotic experience. Or again, to say it even better, no longer with Nerval but with Deleuze: to think is *thrice victorious* to cross the Acheron.[29] For it is to have the courage to *set out once again* towards the worst of two deaths, after having escaped at least once before: it is to return to the worst, knowing all the while that it is the worst – because, after all, how could one do otherwise?

drawing – may seem, if not a departure, then something of a minor element of Xenakis's *oeuvre* (only a handful of Xenakis's works were composed exclusively using the UPIC). But an examination of the thinking behind this technology sheds much light on the philosophical importance and integrity of Xenakis's work, and its points of intersection with the philosophy of Deleuze (and Deleuze/ Guattari).

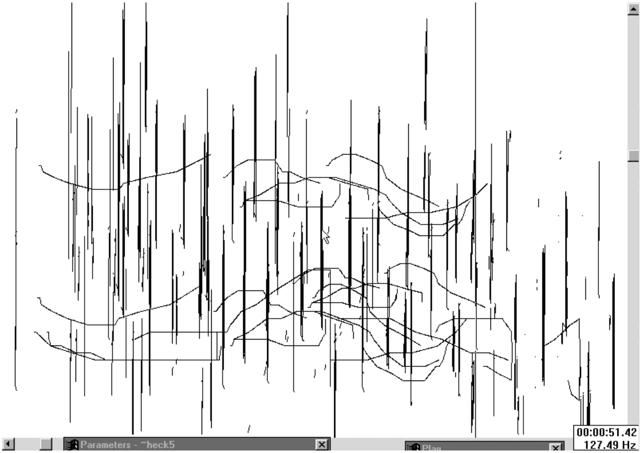
Haswell and Hecker have spoken of the four movements of *Blackest Ever Black* as 'assist[ing] the experience of synaesthesia'.[5] And indeed, the UPIC emerged in the context of Xenakis's lifelong efforts to express in his work abstract forms which he saw as belonging essentially to no particular medium, any more than they were the exclusive province of the sciences or the arts. But what is the significance of synaesthesia, and of the UPIC's graphism-sound translation, in relation to Xenakis's interrogation of music?

For Xenakis, forms themselves were a sort of epiphenomenal 'froth' generated by the ordered relations between multiplicities of elements. To discover the mathematical structures underlying their emergence, and to understand what happened when the composer 'incarnated' them in time, was to require a series of mathematically-inspired conceptual 'generalisations', which saw Xenakis leave all musical tradition behind.

By the time of 1953-4's *Metastaseis*, Xenakis's key conceptual innovations – involving above all a thinking of the dialectical couplets unity/multiplicity, local/global and continuity/discontinuity – were already in place: The use

---

[5] Curtis Roads, *Blackest Ever UPIC*, sleevenotes to *Blackest Ever Black*.



of 'sound masses', 'clouds' or 'complexes', defined through global textural and dynamic properties, and within which a multiplicity of individual lines are locally determined mathematically or statistically; giving rise immediately to the problem of continuity between one mass, state, or constellation, and another – precisely, metastaseis – whence Xenakis's characteristic use of glissandi.[6]

In a reprise of Leibniz's theory of *petites-perceptions*, according to which in perceiving the sound of the sea we operate an 'integration' of infinite unconscious perceptions of individual waves, a crucial inspiration for *Metastaseis* was the wartime experience of 'the transformation of the regular, rhythmic noise of a hundred thousand people into some fantastic disorder' – the mathematics of a political singularity as native workers faced occupying Nazi troops.[7] The question of the nature of continuous transitions intersects with the question of the individuation of masses: why are certain clusters of frequencies registered as 'a' sound, and at what point does it change in nature, becoming many? Throughout *Blackest Ever Black,* simple units of sound gradually, insensibly shift and diverge into separate lines; as if, where there previously was a cloud or a swarm, we now see its constituent members, waves subtracted from the sea.

---

[6] Equally so in his architectural work – the Philips Pavilion, constructed during his time working with Le Corbusier, and employing the same curve functions as the *Metastaseis* score, constituted 'a glissando in space' (Varga, *Conversations*, 24).

It was not only mathematics, but equally a close attention to the physical and perceptual parameters of sound as *material,* that would allow Xenakis to escape the impasse he diagnosed in serialism,[8] towards what could properly be called a structuralism, indeed a post-structuralism.[9] For the latter, serial music would be just another fetter to be shed,[10] a brake on the exploration of the objective Idea (in a quasi-Platonic sense, as we shall see) of music, informed by a sonic materialism.

According to Xenakis, serialism's baffling overcomplexity for the listener stems from its being based upon insufficiently interrogated categories of musical thought. The theoretical passing over of the greater part of the complex transformations that intervene between the tone-row and sound-matter itself, mean that what is quite systematic 'outside-time' becomes disarrayed 'in-time' as those dimensions

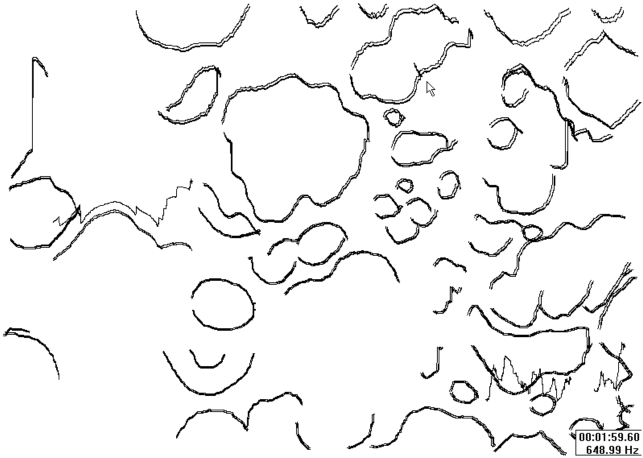
of sound suppressed under serialism's 'tautological unity'[11] emerge haphazardly in auditory experience, uncontrolled and unorganised. Serial music also leaves 'out of account the problem of continuity-discontinuity':[12] Although, naturally, continuous and discontinuous change took place within compositions, the problematic was not afforded the attention Xenakis believed it merited in music as in mathematics.[13] And so ultimately, the rigorous but arbitrarily-applied system of serialism failed the intelligence of the musical ear. To rectify this situation, Xenakis would seek an understanding of both the logic of musical perception and the mathematical structure of music, bringing them together into a new, generalised theory and practice.

---

[11] Xenakis, *Formalized Music*, 204.

[12] Xenakis, in Varga, *Conversations,* 76-7.

[13] *Ibid.,* 72-3.



This would enable him to 'fertilize'[14] music with mathematics, rather than imposing formal systems upon music with little regard for the knot intricating together mathematics, music and the physical sciences since the dawn of Western Civilisation.[15] In order to theorise how 'to make the sound itself live', it had to be realised that 'the inner life of music is not only in the general line of the composition, of the thought, but also within the tiniest details'.[16] If on the macrocompositional level serialism represented a necessary escape from the tonal,[17] its proponents' lack of attention to timbre[18] or to the analysis of sound masses bespoke a failure to listen to what the sound was telling them, beyond the overcoding they had imposed upon it. Ultimately the richness of sound overflowed their enterprise. The UPIC would need to apply a 'new simplicity', it would map the structure of music beginning with sound itself.

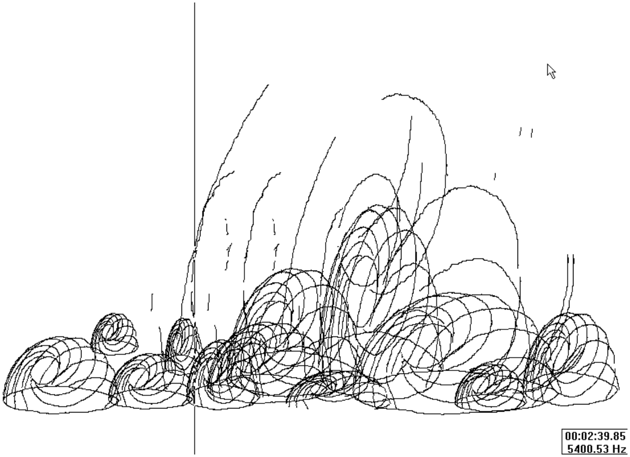
---

[14] Revault d'Allones's expression, in I. Xenakis, *Arts/Sciences:Alloys*, trans. S. Kanach (NY: Pendragon, 1985), 386.

[15] As is well known, Messiaen's benificent influence on Xenakis began with his advice not to worry about conventional musical studies, but to use what Xenakis already had at his disposal: his knowledge of mathematics, and his Greek heritage. Xenakis's theoretical work is deeply rooted in his researches into presocratic thought (see Xenakis, *Formalized Music* 201-209).

[16] Xenakis, in Varga, *Conversations,* 64.

When Boulez later denounced Xenakis's music as 'too simple', Xenakis would argue that 'if music reaches a point where it has become too complex, you need a new kind of simplicity. Complexity is not synonymous with aesthetic interest.'[19] That the UPIC, in particular, was used as proof of lack of sophistication by Xenakis's detractors indicates a



---

[17] *Ibid,* 54.

[18] *Ibid.*

[19] *Ibid.,* 29.

failure to understand the principle at work: 'a maximum of calculated sobriety in relation to the disparate elements and parameters' is necessary in order to 'open onto something cosmic'; 'a sober gesture, an act of consistency, capture or extraction that works in a material that is not meager but prodigiously simplified, creatively limited, selected.'[20]

With the UPIC, Xenakis realised the plan (conceived during his time with *musique concrète* pioneer Pierre Schaeffer in the early 1960s)[21] of extending to the *molecular* level of sound the theories that he had already applied to *molar* statistical aggregates on a macrocompositional level in exploring the problems of continuity and individuation of sound masses. With the use of computers, 'the circle would become complete, not only in the field of macroform but also in the smallest domain, that of sound synthesis.'[22]

But within this domain also, Xenakis immediately identified – and set to work breaking from – conventional wisdom: electronic sound-synthesis at the time was based exclusively upon Fourier's demonstration that any complex wave can be analysed into a series of simple sine waves.[23] Rather than assembling sound from such notionally 'natural' ready-mades (virtual regularly oscillating bodies), CEMAMu's approach would be to 'take the pressure versus time curve as a starting point – that is, what we hear' – a continuous series of intensities (differences in pressure) of arbitrary complexity: 'Instead of going backwards, we start with the curve', says Xenakis;[24] 'I wanted to take possession

of the sound in a more conscious and thorough manner – *the material of the sound*'.[25]

But if the 'crisis of serialism' and the journey into concrete sound helped break out of the stave, reinforcing the fact that 'sound is much more general than pitch',[26] and that '[i]t's important […] to go beyond the limits of the pitch versus time domain',[27] Xenakis had already been instinctively drawn to 'impure' sounds, the 'rougher […] richer' tones possible through unconventional usages of acoustic instruments, precisely because they produced effects falling outside 'the traditional pitch versus time relationship and the musical idea that is linked to it'.[28] So that when he came to work with Schaeffer, Xenakis found no difficulty in understanding why the latter 'despised sine waves' and worked instead 'with concrete sounds because they are really alive,'[29] and soon set about providing the enabling technology for the experimental electronic 'biology' of this sonic life.[30] In the wake of works such as *Metastaseis*, with their gigantic hand-drawn scores, and ever-enthusiastic for a 'generalisation' of methods and technical automation (Xenakis, for whom the orchestra is 'a machine […] which makes sounds'),[31] in the late 60s he began work on what would become the UPIC, a system allowing the composer to experiment interactively, using graphical gestures, with 'the material of the sound'.

[26] *Ibid.,* 67.

[27] *Ibid.*

[28] *Ibid.,* 67.

Just as serialism demanded specialist knowledge and codes, so early computer music systems demanded a detailed technical knowledge. Again, the UPIC aimed to break decisively from this, using a simple pen and tablet interface to focus attention on the act of composition. The composer would be given the simplest and least intrusive tool to realise their musical ideas, and would meanwhile participate implicitly in Xenakis's probing of the alliance between mathematical structure, the physics of sound, and the psychology of musical perception; between abstract structures, material synthesis, and artistic composition.

The UPIC puts the composer in control of every level of what is presented as a minimal hierarchy of composition – from the creation of waveforms that will determine the

timbre, volume and intensity of the sounds to be employed, to the 'orchestration' of these voices into 'pages' of the score, and the mixing and layering of pages into a final recording. Importantly, no level of the hierarchy need ever be closed off in order for the composer to work on the next;[32] one might then describe the system as one of 'transparent stratification', rendering completely open to experimentation the levels of organisation necessarily in play in any musical composition. In addition, the UPIC user decides how, in Xenakis's terms, to bring the 'outside time' pages of the score 'into time': A page of music could be assigned, in the first version of the UPIC, a duration from 0.2 seconds to 30 minutes,[33] in later versions from 6 milliseconds to 2 hours.[34]

---

[32] Lohner, 'The UPIC System', 46.

[33] *Ibid.*, 48.

[34] Roads, 'Blackest ever UPIC'.

This unprecedented elasticity of musical time encouraged by the UPIC is present as an ordering principle in *Blackest Ever Black*, where Haswell & Hecker use elements whose family resemblances are barely consciously recognisable, as they undergo extreme transformations, morphing from the instantaneous to the highly attenuated.

> The molecular has the capacity to make the *elementary* communicate with the *cosmic*: precisely because it effects a dissolution of form that connects the most diverse longitudes and latitudes, the most varied speeds and slownesses, which guarantees a continuum by stretching variation far beyond its formal limits.[35]

This simultaneous harnessing of the cosmic and the elementary makes of the most radical material experimentation at the same time a radical democratisation

of means. *Contra* any theoretical elitism, the UPIC's lines of sound provide a 'more universal'[36] medium to 'produce, explore, and create new musical worlds' – 'everybody can understand a line'.[37] Theory-laden avant-garde practices ultimately operated a new overcoding of the music they had liberated from the classical tradition, at once constituting a new priestly caste versed in particular theories, and cutting off whole tracts of unexplored terrain, creating, in Xenakis's word, new musical 'islands'.[38] Whereas the stave is an unresolved mix of the symbolic and graphical, and whereas serialism tended only to exacerbate this condition whilst at the same time reterritorialising upon a model drawn from badly-analysed structural composites (the twelve tones and their transformations) – as if one had dismantled the house of music only to rebuild it using an esoteric new system of construction, rendering it uninhabitable in the process – with the UPIC, Xenakis sought to attain maximum deterritorialisation by using a technology unmediated by theories because based exclusively on elementary acoustics,[39] but allowing the composer, through the graphical interface, sensitively to construct a new *habitus*, a minimum reterritorialisation ('just a little order [...] to protect us from chaos'):[40] a tool that operates not with overcoded conventional points, but with 'graphisms',[41] '*arcs sonores*'.[42]

---

[36] Xenakis, in Lohner, 'Interview', 51.

[37] *Ibid.*

[38] Xenakis, in Varga, *Conversations,* 54, 59. Xenakis would later identify mathematically the transformations of serialism with the Klein Group.

It is this twofold goal of maximum deterritorialisation and universal accessibility that Xenakis calls *polyagogy*.[43] And it is important to observe that the UPIC was not conceived merely as a way to make experimental composition more efficient for the composer, but moreover as a way to make it literally 'child's play'. Xenakis's commitment to opening up these new spaces of musical freedom to all was indicated at the founding of CEMAMu, which sought to establish 'a new general level of awareness' through the recognition, and practice, that 'everyone is creative,'[44] and by enabling and encouraging children to 'evolve away from the tonal

system still generally prevalent in Western civilization.’[45] It is not that the child can ‘play at’ being a composer, but that the composer finds himself raised to the status of the child in relation to sound, having to jettison all he ‘knows’ about music: solfeggio, harmony, counterpoint, and so on, all turn out to be obstacles in the way of a real becoming-music (just as Messiaen had divined in the case of Xenakis himself). The employment of manual gesture creates a direct coupling between sound and mind (‘direct to the *mind*’;[46] ‘The hand is the organ of the body that is closest to the brain’[47] – with the UPIC, ‘we can solve the problems of the composition directly, with our hands.’)[48]

Image:Ateliers UPIC

It is not so much any particular piece composed with the UPIC that matters, but this *becoming* in which the user learns a ‘hand-eye-ear’ coordination as novel to the seasoned composer as to the child, an ‘interdisciplinary pedagogy through playing’.[49]

Blackest Ever Black recovers the power of this vision, thirty years after the first working model of the UPIC was completed, and in an age where the digital manipulation of sound has become ubiquitous to the point of banality. Xenakis’s vision for a mass-market production of the UPIC[50] failed, of course; but in certain sense his pioneering explorations of sound did presage modern pop producers for whom ‘sonic construction’ is the object of meticulous technical adjustments quite divorced from any traditional musical concerns. But equally, in an age of digital sampling, where a second of the most anodyne pop recording has been subjected to more electronic manipulation than Stockhausen's entire *oeuvre*, we might ask how the UPIC can stand as anything other than a relic of a highbrow dream, whose austere, uptight, still too-classical sensibility was overturned even as its aims were realised in popular musics.

---

[49] This is carried even further in the latest versions of the UPIC which allow realtime manipulation.

[50] See Lohner, ‘The UPIC System’, 44.

The evolution of electronic instrumentation has taken us from a machine where the musician must physically link up circuits and oscillators, through keyboards with banks of pre-programmed sounds, to sampling technology, where any sound can become a ready-made instrument. Now hard-disk recording, like the UPIC, gives access directly to 'the curve', to a base-level sonic material which is transparently stratified and editable on all levels. Indeed, it is quite possible using HDR to 'draw' waveforms onto the screen just as in the UPIC. But the extreme facility and infinite potential of this technology seems to fail Xenakis's test of the power of simplicity, and in contemporary dance music the gap is all too often filled by barely-remixed tradition and modish cliché. Despite honorable exceptions, for the most part dance musics remain tonal and monorhythmic, composed of recognisable samples or fourier-synthesised tones.[51] It is tempting to venture an analogy between music and videogames (1978 being the year of *Mycenae Alpha* and *Space Invaders* alike): where the rudimentary technology of early games demanded a real and compelling synaesthetic becoming between human and machine, contemporary games, with their immaculate representational capabilities, can, and all-too often do, fail to create that symbiotic bond, becoming glossy representational entertainment instead.

---

[51] It is also noteworthy, and reflects some of the paradox of Xenakis's legacy, that whilst UPIC aims at a maximal 'generalisation' in all dimensions, as Curtis Roads remarks, 'the sound palette of the UPIC is utterly singular' (Roads, 'Blackest Ever UPIC') – unlike HDR, it is, properly speaking, a musical instrument. Unless used in a spirit of deliberate obfuscation its sound-space is quite characteristic and has real integrity. Of course, this recognisable consistency owes something to the fact that Xenakis's aim with UPIC, as with his composition, is never to explode and destroy, but to isolate just what it is that holds things together: what is sonic consistency?

The key to appreciating the UPIC's continued importance, therefore, is to understand it in the context of the polyagogical campaign to liberate children from Western musical heritage before they had been enculturated into it. Now, it may well be that in reterritorialising the abstract matter of sound back upon the landscape of excitational attractors and rhythmic tics, the outer edges of pop music initiate a slow drift of the human towards the plane of abstract sound, through a rhythmic contagion that we might place side-by-side with this polyagogy. Indeed, this subterranean kinship is dramatised in the lightshows and quaking electronic sub-bass eruptions of Haswell and Hecker's 'UPIC diffusion sessions', which continue a tradition of 'disorienting, hallucinatory light-shows'[52] engineered by Xenakis himself. But popular electronic music tends to thrive on producing excitation via jarring, violent sonic alienations; whereas, if simply listening to *Blackest Ever Black* heralds the shock of an encounter with sound as if for the first time, this should not obscure the fact that Xenakis envisioned a participatory and continuous process of sonic re-education (or de-education), with the hand-eye interface of the UPIC providing the graceful 'glissando' between the natural proclivities of the human ear and the vast virtuality of sound.

Creating a 'plane of consistency' between the hand-eye

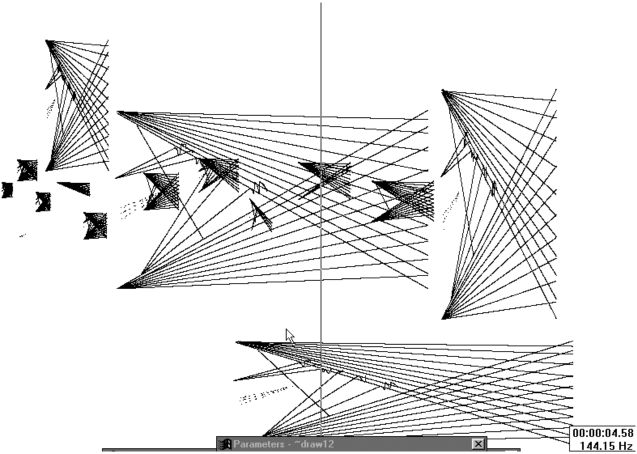
apparatus and sonic materiality, the UPIC realises an abstract phylum that spans both and which is the seat of synaesthesia. In occluding forms and their production behind opaque codes, symbolic practices (such as serialism) militate against synaesthesia: the 'section' they take through musical possibility is not a clean enough cut. Of course, synaesthesia is not a goal in itself, either for Xenakis, for the UPIC, or for Haswell & Hecker; but it seems to play the role of a sign that one has accessed forms no longer belonging to the human organism and its perceptual system, but traversing it from the outside.

Beyond this vision of a 'becoming', polyagogy might also be said to correspond in certain respects with Deleuze's call for an experimental programme of 'transcendental empiricism'; it initiates an encounter that lays bare the *audiendum* – that which can only be heard, and therefore



cannot be heard qua (re)cognisable;[53] that is to say, sound-material as series of intensities, or differences in molecular pressure – the 'phenomenon closest to the noumenon':

> [W]e are in a kind of continuum from […] usual objects that we use in music down to the aspects of music that are inaudible, but which produce these events on a higher level.[54]

Further, it offers a theoretical possibility of accounting for how this material is integrated, individuated, amassed into recognisable forms, opening the way to a 'disjointed, superior or transcendent exercise'[55] of the musical faculty.[56] The UPIC reinstates a phylogenetic link to the noumenal continuum or the hidden in-itself of sonic difference, allowing us to render sonorous that which cannot/can only be heard. Whereafter, '[i]t is now a problem of consistency or consolidation: how to consolidate the material, make it consistent, so that it can harness unthinkable, invisible, nonsonorous forces';[57] 'to elaborate a material of [sound] in order to capture forces that are not sonic in themselves.'[58]

[53] See *Difference and Repetition*, 138-45.

[54] Xenakis, in Lohner, 'Interview', 53.

[55] *Difference and Repetition*, 143.

[56] See *Difference and Repetition*, 138-45.

This raises the question of expression: In *Blackest Ever Black* Haswell & Hecker use the UPIC as a stenographer to translate into sound graphisms ranging from images of contemporary events, to their own designs, and finally surrealist automatic drawings. But of course there is no question of 'dumbly literal sonic analogy'[59] here. The UPIC may 'allow the child to find out what a fish, a house, or a tree sounds like,'[60] just as Haswell & Hecker give us the opportunity to 'listen to the shapes of leaves, terrorist atrocities and kebabs.'[61] But neither invite us to play a game of recognition, but instead draw us into a polyagogical *dérive*. Just as synaesthesia, far from being a sort of harmony between recognisable forms, is a sign that one is encountering something from outside, so what is 'expressed' in UPIC works are these structures that intersect us obliquely: it is the machine that will *instruct* us as to what the drawings are really 'of' so that we are momentarily transported outside ourselves; inciting us to further polyagogical investigation.[62]

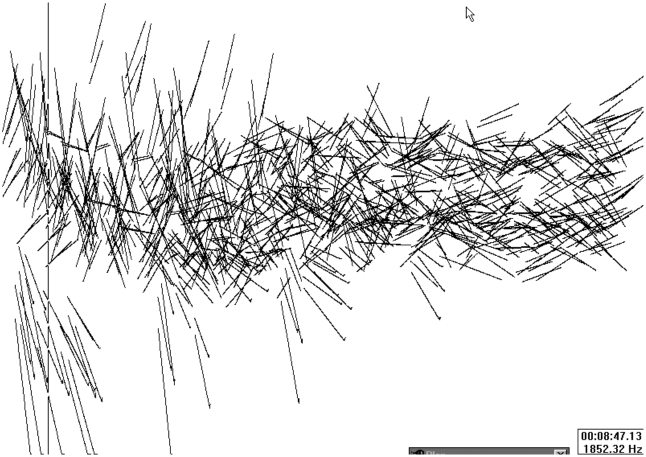
[62] In relation to the notion of expression, it should be noted that for the 1976 defence of his doctorate (published as *Arts/Sciences: Alloys* – see note 14 above), Xenakis chose

Throughout its four movements *Blackest Ever Black* is haunted by fugitive figures from outside, sonic personae in closely-marshalled crowds. The listener naturally tries, but ultimately fails, to apply to them the test of recognition: cicadas, screaming fireworks, foaming waves, crackling clouds of static, swarmachines of sound. Sometimes the glissandi and the sonic latitude recall those 'cosmic' instruments that lurk in the margins of the orchestra, indicating the spaces beyond – the onde martinot beloved of Messiaen (which 'make[s] audible the truth that all



Michel Serres as one of the panel; the Serres whose *Le Système de Leibniz* (Paris: PUF, 1969) advocated reading Leibniz as a proto-structuralist, for whom the relations uncovered by different modes of knowledge were more or less distinct expressions of a universal structural order. From this point of view, one might profitably investigate the relation between Leibniz's *mathesis universalis*, Xenakis's 'global morphology', and the work of A. Lautman (recently republished as *Les mathématiques, les idées et le réel physique*, Paris: Vrin, 2006).

becomings are molecular'),[63] the theremin, the reputedly madness-inducing hydrocrystalophone or glass harmonica, or the inharmonic spectra of the mark tree. But during periods of densely-differentiated sound, the listener feels rather as if she is eavesdropping on an encrypted transmission from another planet,[64] being absorbed into some unknown material in a state of extreme torsion, or witnessing the catastrophic collapse of microphysical filamentary structures, the breakdown of cells or gradual processes of liquefaction; and every so often, an echo of Xenakis's war, the ominous whine of warplanes on the horizon.

Thus *Blackest Ever Black* invokes a universe of unnameable phantom objects, colliding, brushing, scraping, resonating and devouring each other, suddenly expiring or becoming incandescent; sometimes metallic and buzzing with electricity, sometimes mobile and animate (usually insectoid – from Messiaen to Xenakis, 'the reign of birds seems to have been replaced by the age of insects, with its much more molecular vibrations, chirring, rustling, buzzing, clicking, scratching and scraping'.)[65]

According to Xenakis, time, pitch, interval, and intensity can all be characterised as real numbers; but, in the midst of this mathematical regime according to which 'we are all pythagoreans',[66] *timbre* is not structural and cannot be ordered; it is a matter of vague zones of indiscernibility, connected in topologically unforeseeable and manifold fashions[67] – ORGAN PIPE TO MEET LITTLE FLUTE ON THE PLANE OF CONSISTENCY.[68] The system of heterogeneous series of quantitative multiplicities is coupled with a qualitative multiplicity of the Bergsonian-Riemannian (the conjugation is Deleuze's, of course) continuous manifold type, on the basis of a subterranean play of pure difference. And, in this sound-world of 'protoplasmic-like material'[69] ('material [as] molecularised matter')[70] which so scandalised Xenakis's peers, continuity is the rule. Terrestrial instruments become families of topological invariants (varying according to size and elasticity of materials); and outside their multidimensional, infinite yet circumscribed zone, lurk instruments with which we are by rights, as Leibniz would say, incompossible. The 'stretching [of] variation far beyond its formal limits'[71] precipitates a type of cosmic regression to the embryonic state of music – *before music was born, there was the great vibrating cosmic egg, the organ-without-organs*: 'Embryology

already displays the truth that there are systematic vital movements, torsions and drifts, that only the embryo can sustain: an adult would be torn apart by them.'[72] As Haswell & Hecker duly demonstrate, the UPIC's polyagogy gently returns composer and audience alike to a larval state, giving us a way of traversing and inhabiting this whole extended sonoverse, with 'just a little order'[73] to survive these wrenching transformations. Rather than throwing us in at the deep end, polyagogy, comprising a cartography of the objective Idea of music, teaches us to swim in sound; as described by Deleuze:

---

[72] *Difference and Repetition,* 118; '"Regression" will be misunderstood as long as we fail to see in it the activation of a larval subject, the only patient able to endure the demands of a systematic dynamism' – Deleuze, 'The Method of Dramatisation' in *Desert Islands and Other Texts*, 98.

> To learn is to enter into the universal of the relations which constitute the Idea, and into their corresponding singularities [...] To learn to swim is to conjugate the distinctive points of our bodies with the singular points of the objective Idea in order to form a problematic field.[74]

Polyagogy as discipline of becoming and problematisation of the body: What Xenakis says of performers of his music surely filters down to the audience also: 'I do take into account [their] physical limitations […] but what is limitation today may not be so tomorrow.'[75] 'It is the composer's privilege to determine his works, down to the minutest detail'[76] but this also will 'give the artist […] the joy of triumph – triumph that he can surpass his own capabilities'[77] in an encounter with a higher order of generality that reunites and reconnects actually-existing-musics ('islands')[78] into an pangaeic, cosmic Idea in continuous variation:

---

[75] Xenakis, in Varga, *Conversations,* 65.

[76] *Ibid.,* 56.

> We should be able to construct the most general musical edifice in which the utterances of Bach, Beethoven or Schönberg, for example, would be unique realisations of a gigantic virtuality.[79]

Regardless of whether Xenakis regrets the 'perpetual compromise'[80] that prevents him from being a 'pure ontologist' like Parmenides, he realises that such 'perpetual compromise' is also a 'perpetual exploration'[81] of this virtuality, a transcendental empiricism. For music is in fact nothing *but* this compromise between the mathematical and the biological, between structure and hand, between the Idea 'outside time' – a continuous plane populated by 'tones without sound'[82] – and their qualitative manifestation under certain conditions of selection, those of the duration which 'we' are. Here we remark Xenakis's proximity to his contemporary, and Deleuze's mathematical inspiration, Albert Lautman, whose Platonism speaks of a dialectic (comprising precisely those couplets discontinuous/continuous, local/global, unity/multiplicity, which underpin Xenakis's *oeuvre*) eternally inaccessible to us except through an ongoing speculative contemplation of the mathematical theories that 'incarnate' it.[83] Ideas, or problems, are just those things that lie out of reach, that we struggle to grasp, making life both unbearable and bearable, and music recalls this struggle, as 'dream or nightmare'.[84]

[79] Xenakis, *Formalized Music*, 207.

[80] Xenakis, in Lohner, 'Interview', 55.

[81] *Ibid.*, 54.

[82] Lohner, 'The UPIC System', 46.

This allows us to say that synaesthesia is the *anamnesis* proper to the polyagogical apprenticeship: A sensation of that which can neither be heard or seen, 'colours of sound',[85] a 'transcendent employment' of the faculties and the collapse of their borders – it is the remembrance of mathematics in its purest form, disincarnated from even the symbolic. Is music anything else?

As well as his endorsement of the Leibnizian theory of *petites-perceptions*, Xenakis himself also seems to personify a type of 'transcendental deduction' that recalls the hallucinatory theory of perception put forward by Deleuze:[86] the legacy of the war – chronic tinnitus, a lost eye – obliges Xenakis to reconquer the world through abstract principles, venturing 'generalisations' like a solitary musing Beckettian, or one of Kafka's animals, from inside 'a deep well [...] and I'm still there, so that I have to think harder than if I were able to grasp reality immediately.'[87] An undoubted advantage given that, as Bergson showed us, the 'immediate given is not immediately given';[88] and we saw how the UPIC aimed to reproduce this 'becoming-child' in forcing the composer to jettison all they knew about music. This emphasis on reconstructing the world from within sets Xenakis and Deleuze alike against a zen-like model of contemplation: As Deleuze and Guattari argue, in a passage that resonates with Xenakis's rather withering dismissal of Cage's attempts to 'let the universe speak' by suppressing the agency of the composer:[89]

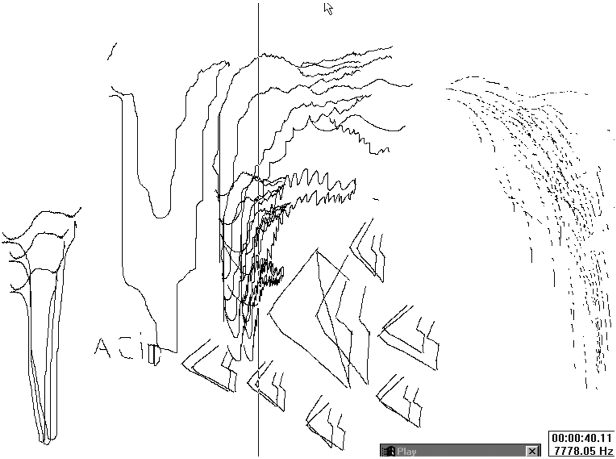
---

[83] See Lautman, *Les mathématiques, les idées et le réel physique*, *op.cit*.

[84] Deleuze, 'The Method of Dramatisation', 99.

[85] Xenakis, in Varga, *Conversations,* 72; 'Increasingly, it is the "colour" of the sound that matters' (*What is Philosophy?* 191). Messiaen himself insisted that he *saw* the colours of music – as 'musician's colours, not to be confused with painter's colours.' – appearing all at once, as in the stained-glass at the Sainte-Chapelle in Paris, which according to Messiaen was a 'luminous revelation' to him. And Xenakis himself (in Varga, *Conversations*, 173) will invoke the 'Inner Colour' that cannot be predicted, even by an experienced composer, from the clusters of individual notes involved. *Cf. A Thousand Plateaus* 347-8: 'the phenomena of synaesthesia […] are not reducible to a simple colour-sound correspondence; sounds have a piloting role and induce colours that *are superposed* upon the colours we see, lending them a properly sonorous rhythm and movement'.

[86] See *The Fold*, 93-4.



---

[87] Xenakis, in Varga, *Conversations,* 48-9.

[88] Deleuze, 'Bergson 1859-1941', in *Desert Islands and Other Texts*, 23.

[89] 'We all have fortuitous sounds in our daily life. They are completely banal and boring … Silence is banal … I'm not interested in reproducing banalities' (Xenakis, *Alloys*, 94-5). Nevertheless Xenakis respected Cage greatly and was an early supporter of his work – see Varga, *Conversations,* 55-6.

> The claim is that one is opening music to all events, all irruptions, but one ends up reproducing a scrambling that prevents any event from happening [...] instead of producing a cosmic machine capable of 'rendering sonorous'.[90]

Contemplation is already action, selection, composition,[91] in so far as this contemplation takes the actively exploratory form of a transcendental empiricism: not content to 'let music be', it attentively probes the being of music in order to discover its material basis and its life.

> In writing electronic music you also have to direct the invention of new tools.[92]

If the greatest creative act is to create something with which to create – to imitate '*physis physeôs*'[93] – then the UPIC could be said to be, if not Xenakis's most important work, then certainly a most significant, if still latent, part of his creative legacy to future musicians, more of whom it is to be hoped will take up the gauntlet of *Blackest Ever Black*'s 'grand celebration of Xenakis's sound universe'[94] and put the polyagogy of abstract matter back into practice, creating a music that 'moves the soul, "perplexes" it'.[95] A music, then, to be accompanied by a philosophy that likewise 'tends to elaborate a material of thought in order to capture forces that are not thinkable in themselves.'[96]

Mathesis, Science and Philosophy[1]

Gilles Deleuze

It might be interesting to define mathesis in terms of its relations with science and philosophy. Inevitably, such a definition remains to some extent external to mathesis itself; it is simple, provisional, and tends only to show that, beyond any particular historical moment, mathesis describes one of the great ever-present attitudes of mind. That is to say that one will find in the following only a critique of the arguments that scientists and philosophers tend to invoke against mathesis, and above all a specification of how the word 'initiated' ought to be understood. Not that we should forget, certainly, the plane of Indian civilisation within which mathesis was deployed; this is most essential. For we will not say that mathesis can be abstracted, in any measure, from this civilisation; but only that at the heart of our Western mentality can be discerned certain fundamental needs which, already, can only be satisfied by mathesis – as a sort of introduction, a preface to itself. From this point of view, Dr. Malfatti's book presents a capital interest. No doubt, other works have since appeared which delve deeper into Indian consciousness, but few introduce the notion of mathesis in itself, in terms of its relations with science and philosophy, better than the present work.

---

[1] Deleuze's text appears as an introduction to Jean Malfatti de Montereggio's *Études sur la Mathèse ou anarchie et hiérarchie de la science* (Paris: Éditions Du Griffon D'Or, 1946).

COLLAPSE III, ed. R. Mackay (Falmouth: Urbanomic, November 2007)
ISBN 978-0-9553087-2-0
http://www.urbanomic.com

It is not easy to understand the exact sense of the discussions that periodically oppose philosophers and scientists – they do not speak the same language. Science installs itself within the object, reconstructing or discovering reality itself at the level of the object of thought, without ever posing to itself the problem of the conditions of possibility. The philosopher, on the contrary, situates the object, as representation, in its relation to the cognising subject. It is of little consequence to him, M. Alquié remarks, to know what matter might ultimately be – atoms, say – since the latter, like every other representation, have a philosophical status only in reference to the mind that represents them. And it is hard to see what difference even the latest discoveries in modern physics could make, for example, to the conceptions of Berkeley, dating from the eighteenth century. Thus a fundamental dualism poses itself within knowledge, between Science and Philosophy – the principle of an anarchy. It is basically the Cartesian opposition between extended substance and thinking substance.

The Cartesian case is all the more interesting in that Descartes never renounced the unity of knowledge, the *mathesis universalis*. And it is intriguing to see how the latter is situated on the theoretical plane: the knowing mind, as distinct as it might be in itself from the extension with which it appears to have strictly nothing in common, nonetheless deploys the order of things in thinking the order of its representations. At the very moment where unity is affirmed, this unity breaks apart and destroys itself.

But in being broken apart, Descartes now remarks, unity finds its true sense in re-forming upon another plane, where it finds its true meaning. In so far as the theoretical disunion of thought and extension is affirmed, so too is the fact of their practical union, as a definition of life. Unity does not come about at the level of an abstract God transcending humanity, but in the very name of concrete life; the Tree of Knowledge is no mere image. The unity, the hierarchy beyond all anarchic duality, is the unity of life itself, which delineates a third order, irreducible to the other two. Life is the unity of the soul as the idea of the body and of the body as the extension of the soul. Moreover, the two other orders, science and philosophy, physiology and psychology, tend to rediscover their lost unity at the level of living man. Beyond a psychology disincarnated in thought, and a physiology mineralised in matter, mathesis will be fulfilled only in a true medicine where life is defined as knowledge of life, and knowledge as life of knowledge. Hence the motto, 'Scientia vitae in vita scientiae'. A threefold consequence follows from this.

Firstly, to believe that mathesis is merely a mystical lore, inaccessible and superhuman, would be a complete mistake. This is the first misunderstanding of the word 'initiated' that is to be avoided. For mathesis deploys itself at the level of life, of living man: it is first and foremost a thinking of incarnation and of individuality. Essentially, mathesis would be the exact description of human nature.

Yet does not mathesis surpass this living human nature? For it defines itself as a collective and supreme knowledge, a universal synthesis, 'a living unity incorrectly deemed human'. Here we must agree: it must be realised that such a definition cannot be immediate but is posited last of all, receiving a precise sense. Prefiguring the relations between man and the infinite, the natural relation unites the living being with life. Life, in the first instance, seems to exist only through and within the living being, within the individual organism that puts it in action. Life exists only through these fragmentary and closed assumptions, each of which realises it on its own account and nothing more, in solitude. That is to say that universality, the community of life, denies itself, gives itself to each living being as a simple outside, an exteriority that remains foreign to it, an Other: there is a plurality of men yet, precisely, each one must in the same way assume his life for himself, without common measure with others, on his own account; the universal is immediately recuperated. And in this sense life will be defined as complicity, as opposed to a crew. For the crew is the realisation of a common world whose universality cannot be compromised or fragmented, and such that in the process of this realisation the substitution of crewmembers becomes both possible and indifferent. Such is science, on the side of the object of thought; or philosophy, on the side of the thinking subject; in both cases we have a dead crew, theoretical, non-practical and speculative. The only living Crew is that of God, and this because there is only one God, whose symbol is the circle, the perfect, indifferent figure all of whose points are an equal distance from the centre. In complicity, on the contrary, there is indeed a common world, but one whose community comes into effect, once more, through each member realising it for himself without a common measure with others, on his own account, and with no possibility of substitution. Clearly, the principal human realities of birth, love, language and death describe this same profile: Under the sign of death, everyone exists as non-substitutable and cannot have himself replaced.

And this, precisely, is the universality of death. In the same way, life is that reality wherein the universal and its proper negation are as one.

What characterises complicity is precisely that it can be ignored, denied, betrayed. The term 'everyone' denies the universal so effectively, at the very moment it affirms it, that it is easy to notice only this negative aspect. Thus, the u consists in passing from a state of latent, ignorant complicity to a complicity that knows and affirms itself as such. Not, certainly, the point where each loves as everyone, but where everyone loves in their singular manner. It is at the very moment when the living being persists stubbornly in its individuality that it affirms itself as universal. At the moment when the living being closed in upon itself, defining the universality of life as an outside, it did not see that it had, in fact, interiorised that universal: realised the universal on its own account, and defined itself as a microcosm. The first goal of mathesis is to assure this awareness of the living in relation to life and thus to ground the possibility of a knowledge of individual destiny.

Beginning with a purely natural and unconscious complicity where each individual only posits himself in opposition to others, and more generally to the universal, it is a question of passage to a complicity that knows itself, where each grasps himself as '*pars totalis*' within a universe that he already constitutes. In other words, federation. Ostrowski, the translator of this work, saw federation in a most curious fashion: 'At a moment [1849] where ancient Germany seeks to reconstruct its federative unity, lost for centuries, but probably to be rediscovered within our own, it will not be without interest to examine the efforts undertaken by this people of bold thinkers to return science to the unity it enjoyed at the outset – back to its common centre.' What is proposed is a federation as a definition of life, not a unity founded upon a cult of force.

Thus we see that unity comes about at the level of concrete man; very far from transcending the human condition, it is its exact description. It must simply be remarked that such a description must position man in relation to the infinite, the universal. Each individual exists only by virtue of denying the universal; but in so far as man's existence refers to plurality, the negation is carried out universally under the exhaustive form of each and every one – so that it is but the human way of affirming what it denies. We have called this mode of affirmation conscious complicity. And initiation is nothing other than this. Initiation does not have a mystical sense: it is the thought of life and the only possible way of thinking life. Initiation is mysterious only in the sense that the knowledge that it represents must be acquired by each person on their own account. The initiate is living man in his relationship with the infinite. And the key notion of mathesis – not at all mystical – is that individuality never separates itself from the universal, that between the living and life one finds the same relation as between life as species, and divinity. Thus, the multiplicity of living beings which knows itself as such refers itself back to unity, which it describes in inverse relief, the circle as the simplest case of the ellipse. This is why we need to take Malfatti's words literally when he reminds us that the circle, the wheel, represents God: 'Mathesis would be for man in his relations to the infinite, what locomotion is to space.'

Mathesis is therefore neither a science, nor a philosophy. It is something else: a knowledge of life. It is neither the study of being, nor the analysis of thought. Furthermore, the opposition of thought and being, of philosophy and science, have no meaning for it, seeming illusory, a false alternative. Mathesis situates itself on a plane where the life of knowledge is identical with the knowledge of life; it is simply awareness of life. Malfatti announces its *cogito* thus: *sum, ergo cogito*; *sum, ergo genero.* That is to say that its method will be neither scientific nor philosophical. To its object, which is quite particular, must respond a particular method.

*

* *

Scientific method is explanation. To explain is to account for a thing through something other than itself. Heat is movement, water is composed of H_2O, but movement as object of thought is only constituted by negating that which it explains – heat qua system of sensible qualities. Equally, when we arrive at H_2O, there is water no longer. We may call these sensible qualities appearances, but it would still be the case that the very definition of the appearance is that it is not given as such. At the other extreme, philosophical method is description in the widest sense of the word; it is that reflexive analysis whereby the sensible world is described as the representation of the cognising subject – that is to say that, here once again, it receives its status from something other than itself. In the two cases of scientific and philosophical method, we discover a new opposition – that of thought and the sensible.

We had defined the object of mathesis on the basis of the opposition between science and philosophy, between the object and the subject of thought. But that was merely a first aspect of the anarchy. For the object of thought is not merely 'thought' as thinking subject; it is also 'object', as sensible object. This gives a new depth to the opposition. Everyday life traces its path within the objectivity of the sensible; objects are outside of us, they owe us nothing, they are their own significations. Philosophically speaking, colour may be a secondary quality, a representation of the cognizant mind; scientifically it may be reduced to the object of the thought 'vibration', as the last word of reality. But it is no less certain that it is given in itself to the individual, without reference to anything other than itself. The individual knows very well that things haven't been hanging around waiting for him in order to exist. The point will be raised that the object is given to me according to a certain aspect, a certain profile, depending on the point of view it is observed from. But this is not a sign of the object's dependency. On the contrary, it is the manifestation of its total objectivity. It is well known that the contemplated object detaches itself from a ground constituted by the set of other objects. Yet, precisely, the object could not sustain any relationship whatsoever with others if this relation remained external to it. For such an object to detach itself as a form upon a ground of other objects, it must first already be its own ground. So that the 3 faces through which the profile of the cube is always given – 3 faces and no more – are already all 6 faces: the cube must already be its own ground. This phenomenon refers the object to itself and not to he who perceives. But to say that the 3 faces are already 6 faces, is to posit the identity of extension (3) and comprehension (6) in the sensible object. Why this identity? Why are the 6 faces given as 3? It is simply because everyday space is 3-dimensional. In taking a moment to reflect, it will be seen that the 6 faces as such only make sense in reference to a plane. The only way for 6 faces to exist *en bloc* in a space of 3 dimensions is to present 3 of them. The identity of extension and comprehension therefore simply defines space. Which is to say that within this space, the sensible object in general, in the name of such an identity, is none other than the concept: the word 'concept' here no longer signifying 'object of thought'.

Let us keep this in mind, it being only one of the moments of the theory of numbers in mathesis. Take the number 7, as analysed by Malfatti: Firstly, 7 is represented by means of straight lines but never by the curved line: it is the appearance of three dimensions. It indicates the truth that every (individual) body can be considered as an extension of surface (4), operating in 3 directions, length, breadth and depth. Secondly, on the other hand, 7 is concept: it does not yet represent the individual become real, but is 'the multiple development of the universal in innumerable individualities; it is the father of time and his image before the divisible time that tumbles in space upon the undulating images of appearance [...] it moves above the appearance.' A philosophical or scientific critique of this conception would surely lead to error: it does not belong to the same domain, nor to the same method.

We saw that this method of mathesis found itself before an opposition to be surpassed: that of the object of thought and the sensible object. For science explains the sensible object through something other than itself, through the object of thought – a new duality, that must in turn be reduced, by reducing this object of thought back to the sensible, quantity to quality. Let us remark generally that this is the very reduction performed by the symbol. The most simple examples suffice to demonstrate this: When I say that the flag is a symbol of the homeland, I essentially present a sensible object as the incarnation of an object of thought, some piece of knowledge. Further, this sensible object is this very incarnation of knowledge. Earlier, in terms of explanation, the object of thought was the *explanans* which could only be constituted through the annulment of the sensible object it sought to explain. In contrast, in the case of the symbol, the symbolising agent is now the sensible object, and the knowledge which it symbolizes is identified totally with it. Fundamentally, the essential symbolic procedure is the poem. Take for example Mallarmé's Fan. Its subject is certainly movement in itself, as pure object of thought, beyond all sensible manifestation. It, also, moves above appearance, which keeps it at a safe distance:

Whose imprisoned stroke thrusts back
The horizon delicately

The poem's whole argument consists in incarnating in a sensible object the thought of movement, in transforming it in this object: and not merely in the open fan, which is not yet sufficiently profoundly mortified within a sensible matter, but in the fan as thing, the closed fan. Mallarmé indicates expressly this passage from the open to the closed: 'The sceptre of pink shores'; 'This closed white wing you place'.

This is but one example, indicating to us the general sense of the symbol, the incarnation of knowledge, the movement of mathesis. Unlike explanation, the symbol is the identity, the *encounter* of the sensible object and the object of thought. The sensible object is called symbol, and the object of thought, losing all scientific signification, is a hieroglyph or a cipher. In their identity, they form the concept. The symbol is its extension, the hieroglyph its comprehension. Whereupon the word 'initiated' takes on its full sense: According to Malfatti, the mysterious character of mathesis is not directed against the profane in an exclusive, mystical sense, but simply indicates the necessity of grasping the concept in the minimum of time, and that physical incarnations take place in the smallest possible space – unity within diversity, general life within particular life. At the limit, we could even say that the notion of the initiate is rationalised to the extreme. If *vocation* defines itself through the creation of a sensible object as the result of a knowledge, then mathesis qua living art of medicine is the vocation *par excellence*, the vocation of vocations, since it transforms knowledge itself into a sensible object. Thus we shall see mathesis insist upon the correspondences between material and spiritual creation.

Let us apply this symbolic approach to man. The thought of the human condition – that is, its comprehension, defines the former as existence separated from its essence. But to say that in man in general, essence and existence are dissociated, is to say that there are several men (extension). For 'if, for instance, there existed in nature twenty men, it would not be enough to investigate the cause of human nature in general' (Spinoza).[2] That is to say that each existence finds its proper essence outside of itself, within the Other. Which is to say that fundamentally, man is not only mortal: he is 'natal'. And if the parents bestow their existence upon their child, for him to do with it as he will, inversely, does not the child see in his parents the very principle of his intelligibility, his proper essence? In so far as the comprehension of the human is defined by the separation of existence and essence, the extension which is correlative to it – identical to it, even – comes down to sexuality: 'man and woman exist in two separate bodies, each one possessing the body of the other within it'. We now see that it is through man that the concept, as identity of extension and comprehension, comes into the world. In other words, *it is sexuality that grounds sensible qualities*; and Malfatti cites the words of Hippocritus: 'Man is dual, and if he were not dual, he would have no sensation.' But we have seen that sensation refers to three dimensions: So that it is not so much sexual duality as the triadic character of love, that should be remarked upon. 'What would individual life be without love of self, which alone can lead it to the life of the species, by reproducing it as eternal being, infinite, in the species? Dualism does not contain real life. Sexual love conciliates the other two, egoism and heroism.' Moreover, it is the life of the world that is established under the ternary sign: becoming qua addition, that is, birth; duration, as the multiplication through which the act of becoming is conserved; and destruction or subtraction.

What will be the human concept *par excellence*, then? God, unity of essence and existence, is conceptualised by the circle: equivalence and rest, indifference of the interfocal zone, and pregenesthetic life. With the ellipse, however (or rather the ellipsoid, always in movement), we will rediscover separation, duality, the sexual antithesis of foci. Space is the passage from the unlimited circle to the limited ellipse, time the passage from the unity of the centre to the dualism of foci: the three dimensions are born. We might define this passage as the birth of the equivocal, with the ellipsis defined as an equivocal circle. Recall how the very object of mathesis was to be found in the problem of life, of complicity: 'It is at the very moment,' says Malfatti, 'when the individual momentarily puts himself in the place of nature, that he returns his own life to the life of nature'. In this sense, sexual love is at the same time love of self and love of the species, man-become-interior and man-becoming-exterior. Let us recall on the other hand the correspondence that presides over the relations living being/universal life and universal life as species/divinity. Thus we will see Malfatti insist on the fact that the genesthetic and the pregenesthetic are inseparable because one describes the other in negative relief: 'Before I was round. Now, I am extended in the form of an egg.' Through engenderment humanity pursues its own immortality, constitutes time as the mobile image of the eternal, seeks the completion of the ellipse in the circle. To be precise, ecstasy is nothing other than the act by which the individual is raised to the level of the species. For the species can only be thought at the limits of the circle – before the fall Adam existed as *humanitas*.

---

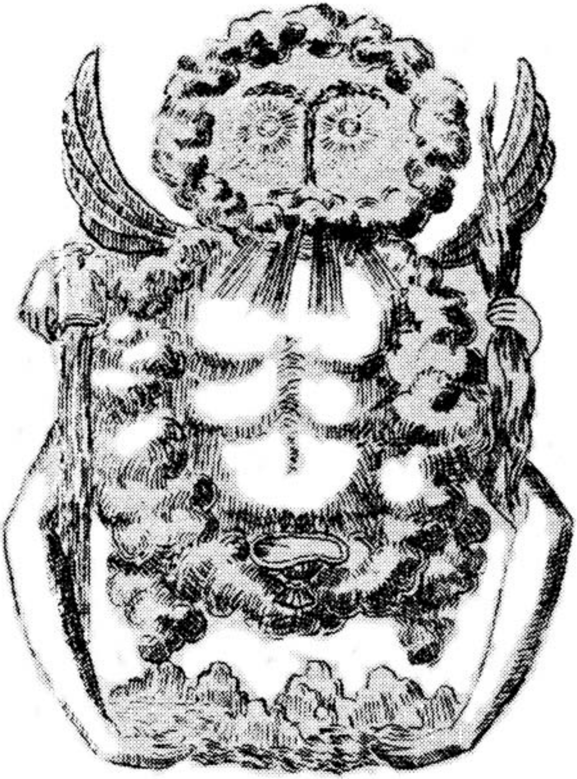
[2] [Letter 39, to Huyghens. – trans.]

It comes as no surprise that the method of mathesis rejoins its very object. It is through the same movement that mathesis situates itself beyond the opposition thinking subject/object of thought, and also that other opposition object of thought/sensible object. We will see this even more clearly with the problem of numbers. On the one hand, number exists only within the decade, that is to say, within numeration: it seems to be constructed by a mental act, transparent to itself, in the process of which we merely add a unit to the preceding number. So that number seems to be on the side of the thinking subject; and yet it is revealed as object of thought qua opacity, endowed with unforeseeable properties to the point where the mental act, supposedly transparent to itself, engenders veritable natures. It is this privilege, on the other hand, that explains why mathesis has granted number a very particular importance: the symbol *is the thought of number become sensible object.* It is intriguing to see the reproach Malfatti addresses to the comparable studies of the Greeks: Their error was to have sought the signification of number in a purely geometrical connection, thus confining it to the object of thought. But, quite on the contrary, it is the symbol, in its full sense, that must be extricated from number. The decade begins with 0, hieroglyph of man and the world, and finishes with 10, unity realised within a complete spiritual and corporeal organism. Malfatti writes of 10 that it 'wearies neither with the action of entering nor with that of leaving. It is the sovereign of the little world (microcosm) within man.'

The definition of mathesis was twofold: In its object, in relation to the duality thinking subject/object of thought; and in its method, in relation to that other duality object of thought/sensible object. We reach a point where these two themes incessantly intersect one another, are identified with each other. The first theme led us to lay down a system of correspondences *between the individual (microcosm) and the universal*; the second, *between the corporeal and the spiritual*. Do not seek, then, a philosophical 'explanation' for the union of the soul and the body. Attempt no longer to critique scientifically the correspondences established between the individual and the universe, under the grand themes of fire, of fermentation ... etc.[3] Mathesis evolves in another domain, in the double depth of the symbol: here it finds its accomplishment, as the living art of medicine, ceaselessly establishing a system of ever-closer correspondences, embracing increasingly individual realities.

---

[3] Similarly, it would be pointless to seek to refute those physiological conceptions put forward, for example, in the Third Study: they belong elsewhere, to 'romantic medicine' and to 'natural philosophy'. These scientific elements drawn upon by Dr Malfatti de Montereggio were far too fragmentary to be sufficient for a complete construction. The author therefore fills the voids with bold teleological hypotheses. It is his weakness, but it is also the inevitable fate of every *a priori* synthesis.



Malfatti's Decade

'Incognitum'

Malfatti's 1845 Studies in Mathesis *attempt to recover the ancient science of mathesis, the 'great unitary system of the contemplation of the world'*[1] *from its fatal declination into, on the one hand, metaphysics, and on the other, mathematics* stricto sensu. *The* 'First Study*' claims to elucidate the metaphysical import of the decade through an examination of its importance in Hindu myth. The correspondences described by Malfatti in this study are elaborated on the basis of some strange and fascinating images from German scholar Nicolas Müller's 1822* Glauben, Wissen und Kunst der alten Hindus (Faith, Knowledge and Art of the Ancient Hindus). *Malfatti avows his indebtedness to Müller, one of those few 'who sought to penetrate the innermost meaning of the materials […] bequeathed us by this greatest of nations to whom we owe the highest of human discoveries'.*[2] *A number of these figures from Müller are reproduced in the 1946 Griffon d'Or edition of the* Studies.

ISBN 978-0-9553087-2-0
http://www.urbanomic.com

In the 'First Study' Malfatti will set forth 'the Indian Organon of mathesis' in the form of a 'symbolic exposition enclosed in an elliptical hieroglyphic, deduced from the ten divine preformative powers and represented through the medium of the ten numerical signs'.[3]

According to Malfatti, the decade must be subdivided into three triads, Brahma ruling over the first triad, Vishnu the second, Shiva the third: Creation (3x1=3: the domain of unity, addition as becoming), Conservation (the domain of multiplication, through which becoming is conserved: 3x2=6), and Destruction (the domain of individuation in creation and destruction, as subtraction qua transformation; 3x3=9).[4] Thus the first three ciphers (1, 2, 3) will describe 'the passage from the sphere and the circle into the genesthetic in the form of the ellipse or ellipsoid, or revelation of the former in the latter', the emergence of the Trimurti (Brahma, Vishnu and Shiva), the 'metaphysical trinity of divine forces'.[5] The sequence of the second triad (4, 5, 6) will represent the passage from hermaphroditism to sexuation, the final triad (7, 8, 9) the passage from the general to the individual.[6]

Through the latter triads, the 'primary divine Trimurti […] passes into an external revelation […] of seven precreative powers […] the primary septuple metaphysical development personified by the allegories of Maya, Oum, Hiranyagarbha, Purusha, Prajapati, Prakriti and Prana […] [T]he cipher 4 belongs to Maya, 5 to Oum,

[5] *Ibid*, 17.

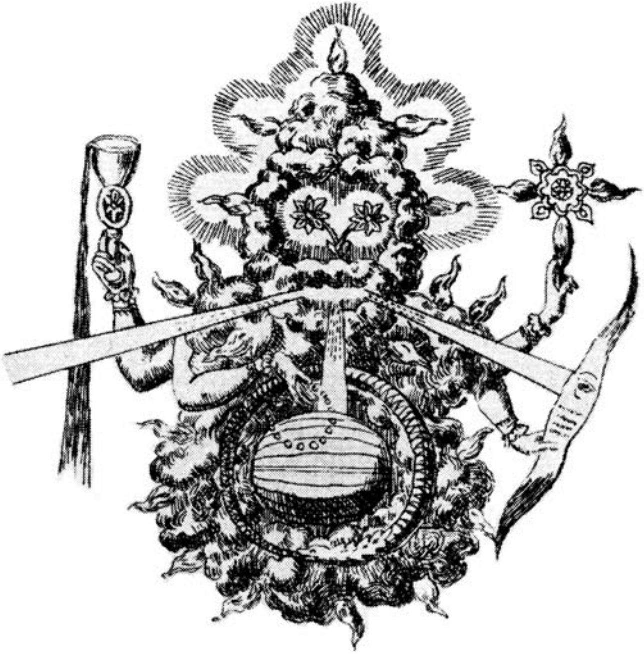
[6] *Ibid.*, 17-8.

6 to Hiranyagarbha, 7 to Purusha, 8 to Prajapati, 9 to Prakriti, and 10 to Prana'.[7]

Malfatti reconstructs mathesis by setting forth the obscure but necessary relation of each of these ciphers to the metaphysical principle personified by the respective deity. The following pages, in which we reproduce selections from Müller's images, along with extracts from Malfatti's text, can only give a reductive and partial impression of the latter's highly involved exposition.

---

[7] *Ibid*.



Brahma = 1, 2, 3: ‘instead of eyes, we find two waterlilies in a form approximating most closely that of the cissoid; beginning together, these two lilies’ stems form the radius (stem) in place of the nose, then are divided in two opposing curves, stop at the curve of the eyebrows – in the middle the curves cross, in the place of the eyes, two lotus flowers, bringing with them the representation of the symbolic spirit – cosmo-generic.’[8]

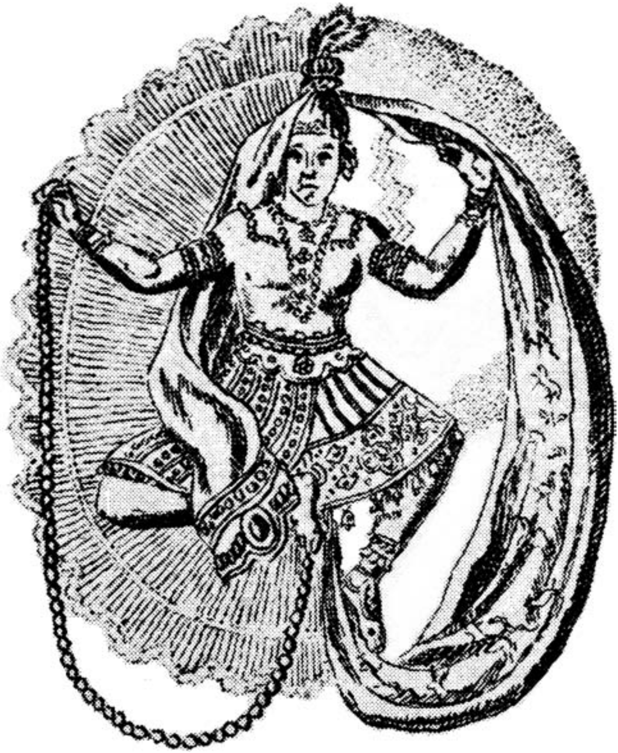
---

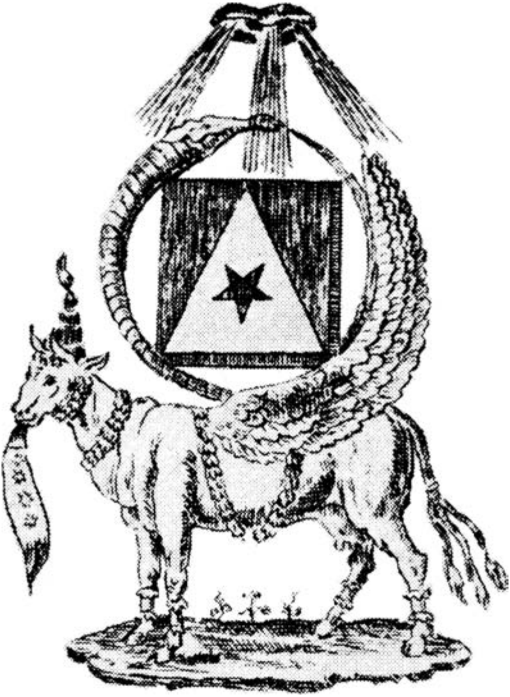
[8] Malfatti, 22.

'Maya = 4 […] as [Maya] opens the second triad of the pregenesthetic decade, so the cipher 4 opens that of the second triad of our genesthetic decimal […] According to doctrine, Maya is the exercise of the threefold force of the Trimurti, as ex-engenderment of the latter […] the passage of the circle into the ellipse […] Female yet endowed with virile force, she is hermaphrodite […] She is half Brahma, half Maya: According to the Veda, the spontaneous act of the separation of double sexuality in the original form of feminine and virile demi-divisibility […] Through a careful examination of her image, we find, around the centre of her stomach, four groups of hanging pearls, the first signification of the number four. But the principal ornament of her clothing consists in a rich and prominent emblem composed of an ellipse enclosed within a parallelogram […] It is to be remarked, and it confirms our point of view, that the paralellogram which encloses the ellipse has the form neither of a square nor of a rectangle parallelogram, but rather that of a lozenge such as one might arrive at by repeating an iscosceles triangle upon its base – which precisely symbolises the deployment of the Trimurti in Maya. – The square, set in motion, becomes a lozenge, as the circle does an ellipse.'[9]

---

[9] Malfatti, 26, 28-9.

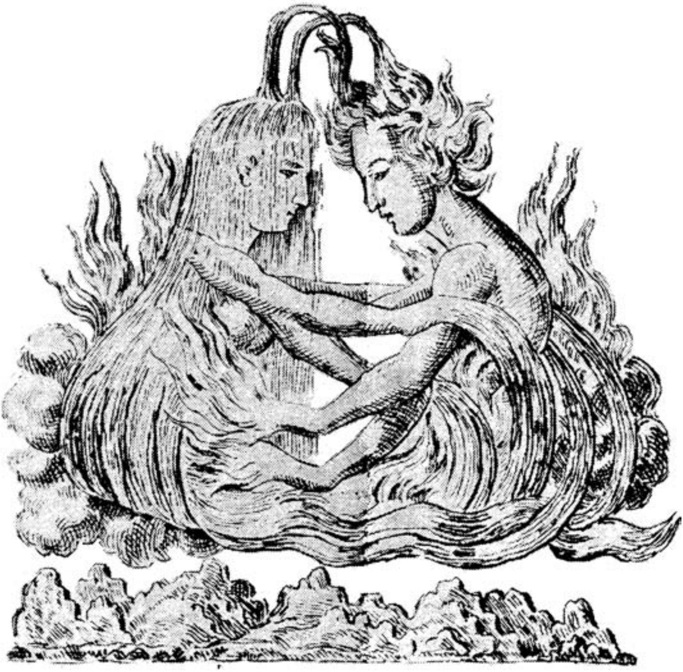




‘Oum = 5 […] The image of Oum, where a circle symbolising infinite time (the serpent of eternity) circumscribes a square in the middle of which is found suspended a triangle.’ Oum is ‘a proclamation of all that becomes; a prototype of the first cosmogenetic development; a breath of original life; the container of a nature to come; the envelope of science; the mystical body of Brahma – the soul of all with and within Brahma.’[10]

---

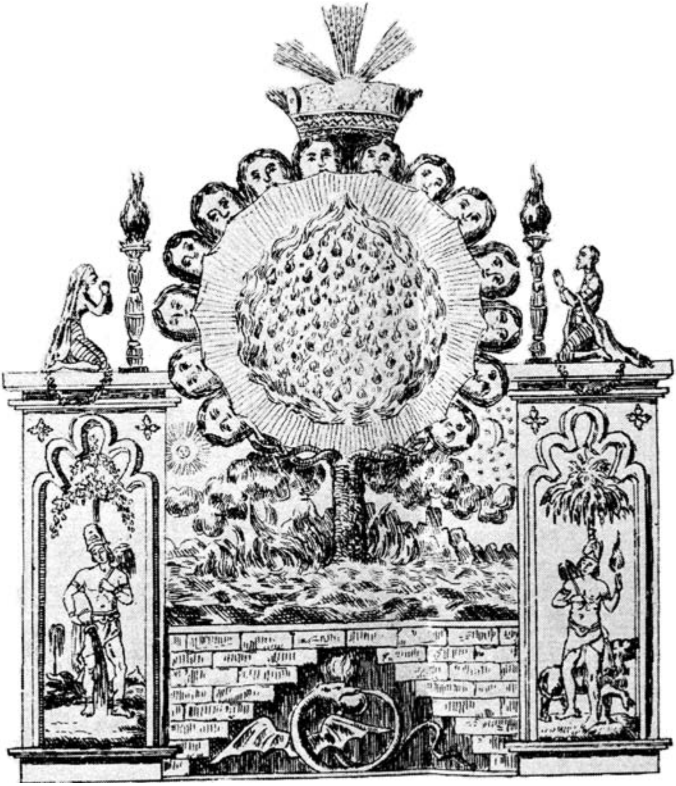
[10] Malfatti, 31-2.



Oum ‘represented in human form, as masculine and feminine in the act of coupling’.[11]

---

[11] *Ibid*., 32.

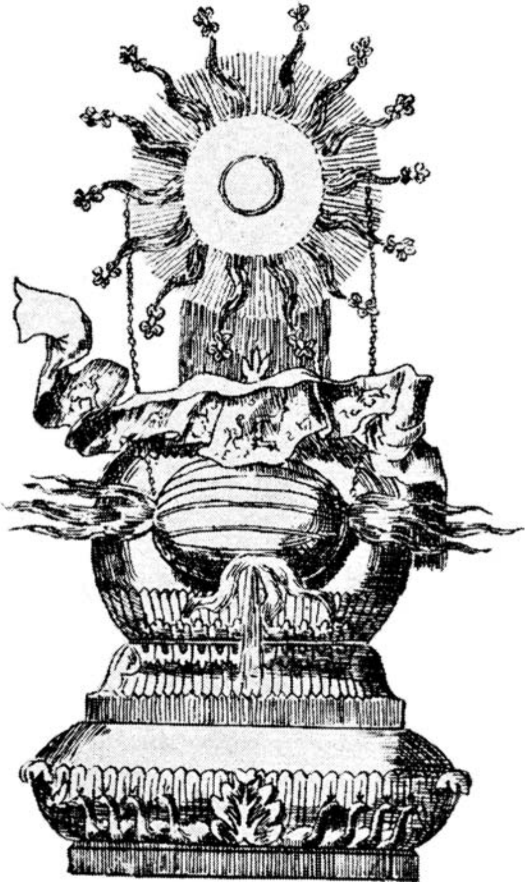


‘Hiranyagarbha = 6’: ‘in 6 […] is substantialised not only the totality received from the ideal and real hermaphroditism as genre, as spirit of the world closed in on itself as the egg of the world […] but also the idea of a development outside itself of finite sex in the third power of 2 = 8, a sex which, in the third triad, is expressed in an infinite individuality.’

‘The allegorical image of Hiranyagarbha consists in an altar decorated with a great altarpiece. An enormous tree-trunk plunging its roots into water, the earth and fire rising below a sky of clouds and lights. In the branches, this tree of the world holds a circle composed of fourteen heads, representing the spirit of the world which reigns in all things. – Inside, enclosed by the circle of heads, is the sea of light and of devouring flames, within which, like tongues of flame, swim the multitude of future individual souls, like golden carp in waters dappled silver by the sun.’[12]

---

[12] Malfatti, 37-8.



'Purusha = 7 […] opens the third triad as passage from the general to the particular, from the species to the individual, and as realisation of the conversion indicated in the second triad of hermaphrodism to sex; only by this token can it be a question, in the third triad, of a truly achieved individuality […] 7 does not however yet represent the individual become real, but firstly the thought of the development of the divine Trimurti through Maya, Oum, Hiranyagarbha, as intermediate members in matter […] The idea of matter can be understood sometimes as atomistic […] and sometimes as dynamic […] The figure of Purusha conforms perfectly to this analysis […] It is a statue of large dimension, before which Brahma moves […] beneath the veil of Maya […] as a sun with powerful rays; thus the atomistic side is indubitably signified by the massive statue, as is the dynamic side by the radiating sun […] But in the middle of the massive pedestal, we see emerge from the egg in the very direction of its axis of longitude, 4 + 3 powerful jets of fire; the same thing happens in the transversal axis, but in such a way that the 4 lower jets extend themselves in breadth and depth, as if in a determined triadic and tetradic manner […] as 4 as two times 2 represents geometrically germination in space (but so far only in ideally – as surface), so also 7 can be understood as 6+1 or 4+3. – In the first case, it is the passage from the second into the third triad through the medium of a new development; in the second case, it is that geometric truth, that every (individual) body can be considered as an extension of surface (4), operating in three directions (length, breadth, depth).'[13]

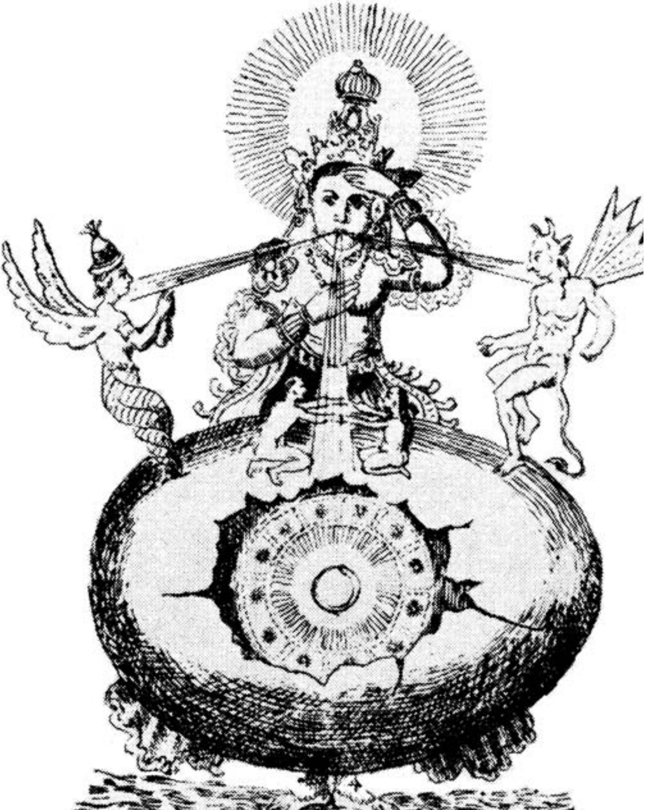
---

[13] Malfatti, 43-4; *Cf.* Deleuze, present volume, 149.

‘Prajapati = 8 […] In eight, individuality is finally obtained, as is seen in the figure of the cipher 8 closed in on itself with a perfect symmetry […] Eight, the third power of the first number pair (more precisely, the feminine principle, reproductive of those that went before), gives the idea of space extended in three directions; not merely geometrically-empty space, but already corporealised space, whereas the interlaced double-ellipse indicates to us, since it signifies an operation of ever-living activity, the individuality which never separates from the world of the universal; – the dualism of mind and body (sex), already expressed in the act of becoming; – the two foci in man, reason and sensibility.’[14]

---

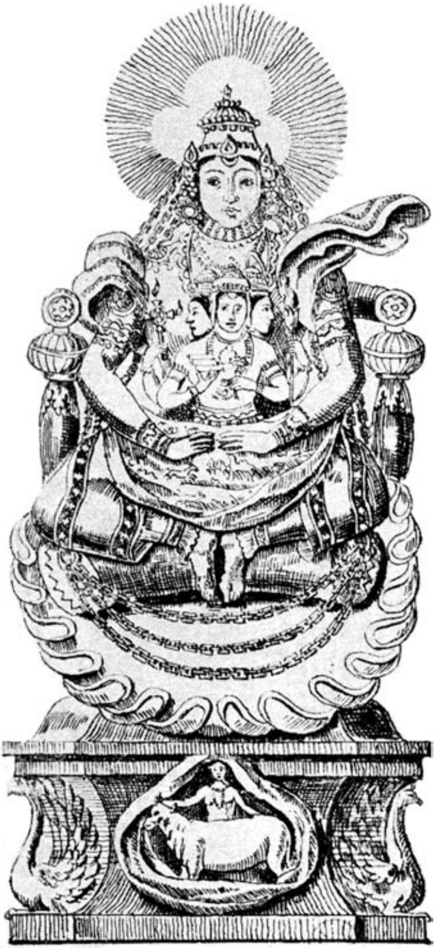
[14] Malfatti, 47.

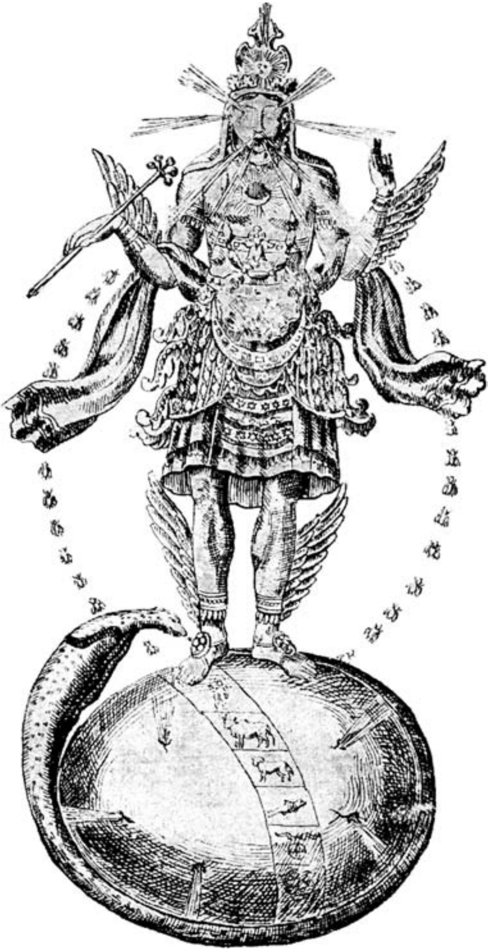


'Prakriti = 9 […] Just like Prakriti's position in the allegories, the relation of the number 9 to the ciphers is that of a conclusion of the third triad of the decimal: 3x3=9. The idea of the individual, which – according to its geometrical meaning, in regard to its participation in the passage from the circle to the ellipse, and properly the sphere into the ellipsoid – is so well symbolised in the number 8. This idea, however, suggested to the profound contemplative faculty of the Indians an aspect of the dependence of the individual, namely that of the triple life of the egg of the world, as sidereal life, telluric life and atmospheric life. – In man it is on one hand the head, the stomach and the chest; on the other hand reason, sensibility, and heart [the soul] […] The image of Prakriti is a woman's figure with the shield of Maya at her feet, seated on a throne whose triangular base has nine surfaces; encompassed by the crown radiated by Brahma which passes across the chains of gold of the pleasure of the senses, she is charged from head to foot with interlaced chains and attaches to the head with points turned above. – In her lap are seated the divine image of the Trimurti, with most significant attributes. – Brahma holds the Veda and a lotus, Vishnu, the circle of the rotation of the world; Shiva, the flaming trident; – Prakriti throws with two hands the models of the forms of Maya into an apron attached in front, and mixes them together. – On the pedestal we see Maya, shifting the veil of the image of the world […] Prakriti was considered to be the fundamental principle of phenomenal change into the intellectual, and, in the physical sense, as the fundamental principle of the immersion of the mind in the bonds of matter.'[15]

---

[15] Malfatti, 50-1.





‘Prana = 10 […] Prana was considered to be the original form of the breath of the world, vivifying all, at the same time that Oum was its mystical body […] The principle of movement in the original form of time and space, the pulsation of nature and the movement of the wind and spiritual pulse (the five winds of life) […] His relation with the external world is expressed by the powerful rays which shine from his eyes, nostrils, ears and mouth, through which he makes the divine essence of life ebb and flow […] Just as the sun radiates above his head, so we see shining, on his chest, the moon with the circle of clouds around his navel. He sits, as king of the breath of life, upon the egg of the world, from which, from five openings visibly give forth the currents of Prana (as image of the universe outside of man).’[16]

Aiôn and Chronos: Deleuze and the Stoic Theory of Time

John Sellars

Gilles Deleuze outlines a supposedly Stoic dual theory of time: on the one hand there is aiôn*, comprising an infinite past and future; on the other there is* chronos*, the extended present. In the scholarly literature on Stoicism, however, either a single theory is reconstructed or the evidence is dismissed as too thin and incoherent. I offer an explanation for this distance between the Deleuzian and scholarly presentations of the Stoic theory of time. I conclude by answering the question to what extent, if any, the Deleuzian theory of* aiôn *and* chronos *deserves to be called Stoic.*

In his 1969 book *The Logic of Sense* Gilles Deleuze embarks on an unexpected engagement with the ancient Stoics.[1] His project in that book is to give an account of

linguistic meaning or sense as a non-existing entity, and in order to do this he draws upon Stoic philosophy of language, in which linguistic meaning is classified as one of four incorporeal entities outside the category of 'being' but within the broader category of 'something'.[2] According to Deleuze, Stoic ontology posits a surface populated on its two sides by corporeal causes and incorporeal effects,[3] although in fact this bears little relation to the ontology of the ancient Stoics.[4] This concern with the ontological status

Beaulieu, 'Gilles Deleuze et les Stoïciens', in A. Beaulieu, ed., *Gilles Deleuze, héritage philosophique* (Paris: Presses Universitaires de France, 2005), 45-72. There are also discussions of Deleuze and Stoic ontology in V. Bergen, *L'Ontologie de Gilles Deleuze* (Paris: L'Harmattan, 2001), esp. 117 ff. and 273 ff.

[2] See *LS* 13-21/4-11. Here Deleuze draws upon Émile Bréhier's *La théorie des incorporels dans l'ancien stoïcisme* (Paris: Vrin, 1928; 9th edn 1997). For a brief overview of Stoic ontology see J. Sellars, *Stoicism* (Chesham: Acumen / Berkeley: University of California Press, 2006), 81-6.

[3] These incorporeal effects are, for Deleuze, also identified with events.

[4] There is indeed a contrast between existing bodies and subsisting incorporeals in Stoic ontology but it is quite different from the two-sided ontology that Deleuze develops in *LS* and credits to the Stoics. The Stoics in fact posit four types of incorporeal, of which linguistic meaning or sense (*lekton*, 'that which is said', often translated as 'sayable') is just one (the other three are time, place, and void). Deleuze's supposedly Stoic 'incorporeal effects' are merely examples of these incorporeal linguistic predicates. There is no Stoic concept of an 'incorporeal event' along the lines that Deleuze suggests. Nor is there any conception of parallel series of bodies-causes and incorporeal-effects inhabiting two sides of a single surface. Deleuze draws upon Sextus Empiricus, *Adversus Mathematicos* 9.211 (*Stoicorum Veterum Fragmenta* [hereafter *SVF*], ed. H. von Arnim, 4 vols (Leipzig: Teubner, 1903-24), 2.341; A. A. Long and D. N. Sedley, *The Hellenistic Philosophers*, 2 vols (Cambridge: Cambridge University Press, 1987), 55B) and takes Sextus's reference to incorporeal predicates as if it were a reference to incorporeals as such. Sextus's incorporeal predicates

of linguistic sense is the principal reason why Deleuze turns to the Stoics but his engagement with Stoicism in *The Logic of Sense* is by no means confined to their theory of incorporeals. He also discusses Stoic ethics and the Stoic 'image of the philosopher'.[5] One might say that Deleuze's principal theme of the logic (or ontology) of sense provides him with a way into a much broader exploration of ancient Stoicism.

Of the various aspects of Deleuze's engagement with the Stoics, it is his account of the Stoic theory of time as a dual theory of *aiôn* and *chronos* that is probably most widely known. In the wake of Deleuze's enormous influence in the English-speaking world these supposedly Stoic concepts of *aiôn* and *chronos* have taken on a life of their own and a quick internet search will turn up a wide range of references to 'the Stoic theory of *aiôn* and *chronos*' in publications from right across the spectrum of Humanities disciplines – from literary theory, film theory, architectural theory, feminist theory, and many others.

However, if one turns to the standard English-language scholarship on Stoicism one will find no reference to such a dual theory of time and no discussion of the terms *aiôn* and *chronos* with the sense that Deleuze attaches to them. The aim of what follows is to ask the question to what extent, if any, are Deleuze's concepts of *aiôn* and *chronos*

---

caused by bodies are merely *lekta* and as such are examples of but one of the four types of incorporeal proposed by the Stoics. On the basis of this misreading Deleuze goes on to construct his two-sided ontological surface. His account is, moreover, inconsistent, sometimes placing sense on the incorporeal side of this surface, other times locating sense on the boundary between the two sides. For discussion of Stoic *lekta* see Sellars, *Stoicism*, 61-4.

[5] For Deleuze's remarks on Stoic ethics see the 20th and 21st series; for the 'image of the philosopher' see the 18th series.

Stoic concepts and, if not, to ask where they came from. This is a fairly modest scholarly task and I do not claim that any serious philosophical consequences follow from my response to these questions. I shall begin by outlining Deleuze's account of these terms and locate his principal source. I shall then turn to the early Stoics and see what has been said about their theory of time. Then I shall move on to the later Stoic Marcus Aurelius who, as we shall see, is particularly significant for this question. We shall also briefly touch upon the discussions of time in Henri Bergson and William James, insofar as they inform the interpretations of Stoicism under discussion. I shall conclude by offering an answer to my question, namely whether the concepts of *aiôn* and *chronos* are really Stoic concepts at all.

1. DELEUZE ON AIÔN AND CHRONOS

According to Deleuze the Stoics proposed two distinct readings of time.[6] Rather than conceive time as a continuum divided into the three parts of past, present, and future, Deleuze suggests that the Stoics separated the present from the past and future. On the one hand the Stoics conceived time as *chronos*, the extended, but limited, living present. On the other hand they conceived time as *aiôn*, the unlimited past and future:

> Thus time must be grasped twice, in two complementary though mutually exclusive fashions. First, it must be grasped entirely as the living present in bodies which act and are acted upon. Second, it must be grasped entirely as an entity infinitely

---

[6] The conceptual distinction is introduced at *LS* 14/5 and elaborated in the 10th and 23rd series, with passing references throughout. For a general discussion see P. Mengue, 'Aiôn / Chronos', in R. Sasso and A. Villani, eds, *Le Vocabulaire de Gilles Deleuze*, Les Cahiers de Noesis 3 (Nice, 2003), 41-7.

> divisible into past and future […]. Only the present exists in time and gathers together or absorbs the past and future. But only the past and future inhere in time and divide each present infinitely. These are not three successive dimensions, but two simultaneous readings of time.[7]

Under *chronos*, the present moment has a certain extension or duration (*étendue ou durée*),[8] an extension that can expand or contract – the present discussion, the present day, the present year, for instance. It can even expand to encompass all of time, becoming what Deleuze calls the cosmic present.[9] From the perspective of *chronos* the past and future are merely parts of some larger present that subsumes the current present: 'the past and future indicate only the relative difference between two presents'.[10] The past and future of the present day – yesterday and tomorrow – are merely parts of the larger present that is the present week. Thus there exists a series of presents of differing extensions enveloping one another, all ultimately enveloped by the cosmic present.

Under *aiôn*, the relationship between the present on the one hand and the past and future on the other is reversed. Instead of a present that can expand and absorb the past and future, under *aiôn* the extended present evaporates in a process of subdivision into part of the past and part of the future.[11] The extended present is replaced by the instant, a mathematical limit without thickness or extension that stands between past and future.[12] If ever we think we have isolated a present moment with any extension in between past and future, it will always be possible to divide it once again into part of the past and part of the future. On this reading no event is ever truly present, having either just happened or being just about to happen: 'no one ever dies, but has always just died or is always going to die'.[13] With *aiôn*, then, we find an echo of Aristotle's discussion of time in *Physics* 4.10, where Aristotle wonders whether time really exists if some of it is in the past and so no longer exists and some of it is in the future and so does not yet exist. The 'now' (*nun*) for Aristotle is an instant without extension separating past and future, and so neither does this exist, for it does not refer to a period of time that is ever actually present.[14]

---

[7] *LS* 14/5. See also *LS* 77/61 and 190/162, where Deleuze labels these two readings *chronos* and *aiôn* respectively.

[8] See *LS* 190/162.

[9] See *LS* 77-8/61; see also 190/162: 'God experiences as present that which for me is future or past, since I live inside more limited presents'.

[10] *LS* 78/62; see also 190/162.

[11] See *LS* 78/62.

It should be clear that these two conceptions of time attributed to the Stoics are radically opposed to one another.[15] The idea of an extended present with a certain temporal extension or duration is incompatible with the idea of a present defined as an abstract mathematical limit. Thus we have two diametrically opposed conceptions of time involving two different conceptions of the present moment (and in order to avoid confusion Deleuze labels the present without extension 'the instant').[16] For Deleuze, the Stoics do not conceive time as something composed of the three elements of past, present, and future. Rather, they read time in two distinct ways: as an expanding and contracting extended present on the one hand (*chronos*), and as an infinitely divisible line of past-future divided by an instant without thickness on the other (*aiôn*)

---

[12] See *LS* 78/62, where he calls this a *pur instant mathématique*, and 193/164, where it is 'the instant without thickness and without extension' (*l'instant sans épaisseur et sans extension*).

[13] *LS* 80/63.

[14] See Aristotle, *Physics* 4.10, 217b29-218a8. For the 'now' being an instant without extension see *Physics* 4.13, 222a10-20. For the infinite divisibility of a continuum such as time see *Physics* 6.1, 231a21-b18. For discussion see R. Sorabji, *Time, Creation, and the Continuum* (London: Duckworth, 1983), esp. 7-16.

[15] We can also note that, for Deleuze, the extended present of *chronos* is intimately connected to the interactions of existing bodies, while the infinite and infinitely divisible past-future of *aiôn* is associated with the subsisting incorporeal effects of the event. These are the two sides of his pseudo-Stoic ontological surface.

(…(…(extended present)…)…)	← past …. | …. future →
	(instant)
finite present	infinite past and future
chronos	*aiôn*

Figure 1. Two Conceptions of Time

Deleuze straightforwardly presents this as an ancient Stoic theory and he cites as his source for this theory a book by the French scholar Victor Goldschmidt on the 'Stoic System and the Idea of Time'.[17] If one has any doubts about whether this really is an ancient Stoic theory then one must turn to Goldschmidt and assess his account and examine the ancient sources that he cites in its support. We shall do this shortly, but first let us turn directly to the ancient Stoics and some of their other modern interpreters.

---

[16] See *e.g. LS* 78/62 and 193/164, noted above.

[17] See *LS* 78/340 ('Victor Goldschmidt in particular has analyzed the coexistence of these two conceptions of time'), with V. Goldschmidt, *Le système stoïcien et l'idée de temps* (Paris: Vrin, 1953, 4th edn 1979). Deleuze also cites É. Bréhier, *La théorie des incorporels dans l'ancien Stoïcisme* (Paris: Picard, 1908; 9th edn Vrin, 1997) as a source for his reading of Stoicism, although he relies on this mainly for his account of the Stoic theory of incorporeals rather than the theory of time.

2. The Early Stoics on Time

None of the works of the early Stoics survive and so in order to consider their theory of time it is necessary to rely upon quotations and doxographical reports of their views. These are inevitably partial, partisan, and sometimes contradictory. The task of determining what the early Stoics thought is by no means easy, then, and this is especially true when it comes of their thoughts about time. The matter is complicated further by the fact that the label 'early Stoics' covers a number of thinkers, each of whom may well have revised their position at some point. It is sometimes assumed by both modern readers and ancient doxographers that there exists just one early Stoic position on any given philosophical topic, but this is not necessarily the case. Moreover, ancient doxographers and modern scholars sometimes assume a philosophical identity between the early Stoa as such and the work of its most prominent figure, Chrysippus. In short, determining what the early Stoic theory of time actually was is a scholarly minefield. With that warning in place, let us turn to consider the evidence.

There are in fact just three texts that report what the early Stoics thought about time, and these are in Diogenes Laertius, Plutarch, and Stobaeus. The last two are longer and include reports relating to different early Stoics so I shall divide both of these in two, giving us five ancient texts to consider:

> (a) Diogenes Laertius 7.141: Time (*chronos*) too is incorporeal (*asômatos*), being the measure (*diastêma*) of the world's motion (kinêsis). And time past and time future are infinite (*apeiron*), but time present is finite.[18]

---

[18] This text is *SVF* 2.520. It is not included in Long and Sedley.

(b) Stobaeus 1,106,5-23: Chrysippus said time (*chronos*) is the dimension (*diastêma*) of motion (*kinêsis*) according to which the measure of speed and slowness is spoken of; or the dimension accompanying the world's motion. And (he says) every single thing moves and exists in accordance with time […] Just as the void in its totality is infinite (*apeiron*) in every respect, so time (*chronos*) in its totality (*panta*) is infinite (*apeiron*) on either side (*eph' hekatera*). For both the past and the future are infinite (*apeiron*). He says most clearly that no time (*chronos*) is wholly present (*holôs enistatai*). For since continuous things are infinitely divisible (*tomê*), on the basis of this division every time (*chronos*) too is infinitely (*eis apeiron*) divisible (*tomê*). Consequently no time (*chronos*) is present exactly (*kat' apartismon enestanai*), but it is broadly (*kata platos*) said to be so. He also says that only the present belongs (*huparchein*); the past and future subsist (*huphestanai*), but belong (*huparchein*) in no way, just as only predicates which are [actual] attributes are said to belong (*huparchein*), for instance, walking around belongs to me when I am walking around, but it does not belong when I am lying down or sitting.[19]

(c) Plutarch, *On Common Conceptions* 1081c-1082a: The Stoics […] do not admit a minimal time (*elachiston chronon*) or wish the now (*nun*) to be partless (*ameres*) but claim that whatever one thinks one has grasped and is considering as present (*enestos*) is in part future and in part past. […] Chrysippus […] says in his book *On the Void* and elsewhere that the part of time (*chronos*) which is past and the part which is future subsist (*huphestêkenai*) but do not belong (*huparchein*) and only the present belongs. But in *On Parts* Books, 3, 4, and 5 he maintains that one part of the present time (*enestêkotos chronou*) is future and the other past. So it turns out that he divides the belonging constituent of time into non-belonging parts of what belongs, or rather that he leaves nothing at all of time belonging, if the present has no part which is not future or past.[20]

---

[19] Cited according to volume, page, and line of C. Wachsmuth, *Ioannis Stobaei Anthologii Libri Duo Priores Qui Inscribi Solent Eclogae Physicae et Ethicae*, 2 vols (Berlin: Weidmann, 1884; repr. 1958). This text is Arius Didymus fr. 26 (in H. Diels, *Doxographi Graeci* (Berlin: De Gruyter, 1879; Editio Quarta 1965), 461,23-462,3), *SVF* 2.509, and Long and Sedley 51B.

(d) Plutarch, *On Common Conceptions* 1081e: Archedemus says that now (*nun*) is a kind of joining and meeting of the past and future […] now (*nun*) is not a time (*chronos*) but a limit (*peras*) of time (*chronos*).[21]

(e) Stobaeus 1,105,17-106,4: On Posidonius: Some things are infinite (*apeira*) in every respect like the whole of time. Others in a particular respect like the past and the future. For each of them is limited only by reference to the present (*paronta*). His definition of time (*chronos*) is as follows: dimension of motion or measure of speed and slowness. And he holds that that time which is thought of in terms of 'when' is partly past, partly future, and partly present. The last consists of a part (*meros*) of the past and a part of the future, encompassing the actual division (*diorismon*). But the division (*diorismon*) is point-like (*sêmeiôdê*). Now (*nun*) and the like are thought of broadly (*en platei*) and not exactly. But now (*nun*) is also spoken of with reference to the least perceptible time encompassing the division (*diorismon*) of the future and the past.[22]

---

[20] This text is *SVF* 2.517-9 and Long and Sedley 51C. I have made use of the helpful text with translation in H. Cherniss, *Plutarch, Moralia: Volume XIII, Part II* (Cambridge, MA: Harvard University Press, 1976).

[21] This text is Archedemus fr. 14 (in *SVF* 3) and Long and Sedley 51C.

[22] This text is Arius Didymus fr. 26 (in Diels, *Doxographi Graeci*, 461,13-22), Posidonius fr. 98 (in L. Edelstein, and I. G. Kidd, *Posidonius, The Fragments* (Cambridge: Cambridge University Press, 1972; 2nd edn 1989)), and Long and Sedley 51E.

These texts are complex and in certain respects seemingly contradictory. The challenge of reconstructing the Stoic theory of time from these meagre remains has not surprisingly led to a number of conflicting interpretations. On the basis of text (a) some have suggested that the Stoics posited a finite present with a certain extension or duration sitting between the past and future each of which are limited by the present on one side but unlimited on the other.[23]

← infinite past … (extended finite present) … infinite future →

Figure 2. Tripartite Theory of Time

This is clearly the polar opposite of Deleuze's reading. Others have suggested that while there is a mathematical limit between past and future, there is also an extended present that overlaps with part of the past and part of the future,[24] in effect combining Deleuze's two opposed readings into one.

instant
← infinite past … | … infinite future →
(extended present)

Figure 3. Revised Tripartite Theory of Time

---

[23] I. G. Kidd, *Posidonius II: The Commentary*, 2 vols (Cambridge: Cambridge University Press, 1988) suggests this was Zeno's position. Sorabji, *Time, Creation, and the Continuum*, 25, attributes this interpretation to G. E. L. Owen (although not citing this text).

[24] See *e.g.* Sorabji, *Time, Creation, and the Continuum*, 25, who considers (but does not endorse) this reading along with the previous reading as 'two rival interpretations of Chrysippus'.

The reading that has tended to dominate modern scholarly discussions rejects both of these possibilities. It argues that for the Stoics the present does not have any extension of its own and when we talk as if it does we are merely talking about a fictitious or specious present. This is the position adopted by Sorabji after considering and then rejecting the other two readings and it is also the position adopted by Long and Sedley in their influential sourcebook.[25] The latter note that according to the sources 'time is infinite in extension and infinitely divisible'.[26] While time as a whole is infinite, past and future are infinite on only one side, limited on the other side by the present. Long and Sedley take 'the present' and 'the now' to be synonymous, being an indivisible durationless point (*i.e.* Deleuze's 'instant'). 'But', they say, 'we are allowed to speak of the present as if it had a duration or existence of its own. That is acceptable at the level of perception, but under strict analysis the present is specious since it "consists of a part of the past and a part of the future"'.[27] In other words, the extended present is merely a popular but ultimately mistaken way of talking (and not a second theory of time). On this reading, there is no extended present of *chronos*, only the infinite past-future of *aiôn*.

There is one piece of ancient evidence that this reading does not take into account. It is the claim reported by Plutarch and Stobaeus that while the past and future 'subsist' (*huphestanai*), the present moment 'belongs' (*huparchein*).[28]

---

[25] See Sorabji, *Time, Creation, and the Continuum*, 21-6; Long and Sedley, vol. 1, 307.

[26] Long and Sedley, *ibid*.

[27] Long and Sedley, *ibid*.

[28] On this distinction see A. A. Long, 'Language and Thought in Stoicism', in A. A. Long, ed., *Problems in Stoicism* (London: Athlone, 1971), 75-113, at 89-93; V.

This word translated as 'belong' (*huparchein*) has sometimes been translated as 'exist'.[29] The present moment belongs or exists in the same sense that the predicate 'I am walking' belongs to me when I am actually walking but not when I am sitting. The important point is that the present is said to have a greater ontological status than the past and future, and this seems at odds with the claim that the present is merely specious.

It has been suggested by Kidd that the Stoic Posidonius tried to overcome this problem by drawing a distinction between two senses of the now (*nun*).[30] According to Kidd, the first Stoic, Zeno, held a tripartite theory of time divided into past, present and future, positing a finite present with a certain extension sitting in between the past and future. Chrysippus rejected the idea of a finitely extended present due to the problem of its infinite divisibility (raised by Aristotle in *Physics* 6.3, 234a11-24), and so was left with only the past and future separated by a limit. However, this left Chrysippus with the paradox of claiming that the present 'belongs' even though it isn't really there. Posidonius overcame this paradox in Chrysippus' position (in which the present is reduced to nothing but still 'belongs') by distinguishing between two senses of now (*nun*), one conceptual and one temporal – the dividing limit and the specious present (these are Deleuze's 'instant' and 'extended present'). While the conceptual present is a mathematical

[30] See Kidd, *Posidonius II: The Commentary*, vol. 1, 395-403.

concept, the temporal present is an extension or interval between two limits where the extent of the interval is not fixed, and so the present can expand or contract, although it remains specious.

Zeno:

← infinite past … (extended finite present) … infinite future →

Chrysippus:

instant

← infinite past … | … infinite future →

Posidonius:

conceptual instant

← infinite past … | … infinite future →

(temporal extended present)

Figure 4. Kidd on Zeno, Chrysippus, and Posidonius

Kidd goes on to draw a parallel with William James,[31] suggesting that the philosophically correct use of the notion of the present is to refer to a durationless limit or instant. This is the conceptual present. However, the foundation for our conception of time is a pre-philosophical specious present of lived time, which is necessarily vague and imprecise. Again, like Sorabji and Long and Sedley, the extended present of *chronos* is rejected as specious and we are left with the infinite past-future and durationless instant of *aiôn*. More recent scholarship has continued with this line of interpretation. In the nine hundred pages of *The Cambridge History of Hellenistic Philosophy* we get just one paragraph on the Stoic theory of time: 'To the Stoics time is an incorporeal continuum which can be infinitely divided. For this reason no time is wholly present inasmuch as the present consists of a part of the past and a part of the future. Past and future are parts of time and stretch out infinitely on one side but are limited by the present, which acts as a kind of joining'.[32] This is again the Deleuzian time of *aiôn*. No attempt is made here to reconcile this with the ancient claim that, while the past and future subsist, the present 'exists' or 'belongs' (*huparchein*).

---

[31] Kidd cites W. James, *The Principles of Psychology*, 2 vols (London: Macmillan, 1890), 1,631.

By way of summary thus far, we can see that according to the recent scholarly consensus the Stoics held a theory of time close to Deleuze's conception of *aiôn*. However, there remains a tension within the ancient sources that is uncomfortable. Indeed, most modern accounts fully acknowledge this and their readings are offered as the most plausible reconstruction of some messy and possibly contradictory doxography. The tension that remains is this: while on the one hand time infinitely extends into the past and future and the past and future are separated by a durationless instant, on the other hand the present moment is said to be extended and to 'belong', which accords it a greater ontological status than the past or future.

Plutarch, who is explicitly looking for contradictions within Stoic philosophy, sums this up best in text (c) above. There he says that while Chrysippus says in his book *On the Void* that 'part of time which is past and the part which is future subsist (*huphestêkenai*) but do not belong (*huparchein*) and only the present belongs (*huparchein*)', in his other book *On Parts* 'he maintains that one part of the present time is future and the other past'. Consequently Plutarch charges Chrysippus with dividing 'the belonging constituent of time into non-belonging parts of what belongs, or rather that he leaves nothing at all of time belonging'. This is the tension that modern scholars try to explain away. The fact that Plutarch cites from two different works by Chrysippus (*On the Void* and *On Parts*) should not be overlooked, and Kidd may well be right to try to sketch a development in Stoic thinking about time.[33] What we may have here are fragments of two different positions held by Chrysippus at two different stages in his philosophical development. But of course such a claim can be no more than speculation.

---

[32] D. M. Schenkeveld, 'Language', in K. Algra *et al.*, eds, *The Cambridge History of Hellenistic Philosophy* (Cambridge: Cambridge University Press, 1999), 177-225, at 191.

There is also an issue of translation here. In the two passages from Stobaeus it is said that the present is *kata platos* and *en platei*.[34] Long and Sedley render these as saying that the present is 'broadly said to be' and is 'thought of broadly', implying imprecisely.[35] We say that the present moment exists but this is imprecise because strictly speaking the present is merely part of the past and part of the future. However, others translate these passages as saying that the present *is* broad or has a certain extension. (Goldschmidt has 'étendue'; Rist has 'extension'; Hadot has 'thickness' in Chase's translation; Brunschwig has 'extended'; Sorabji has 'broadly', to imply thickness, even though he rejects this reading.)[36] On this reading the present is real and is not specious. How we translate this phrase will affect how easily the tension within the doxography can be reconciled. However, one tension will not go away. For even if we dismiss the supposedly extended present as specious, we are still faced with the claim that only the present belongs. Yet it seems odd to say that the 'now' conceived as a durationless mathematical limit can 'belong' in a way analogous to the way in which walking 'belongs' to me when I am walking. On the contrary, walking sounds precisely like a present activity that takes place in an extended, albeit unspecified, duration of time.

---

[33] The only other reference we have to *On the Void* is from Diogenes Laertius 7.140 (*SVF* 2.543) who helpfully tells us that in *On the Void* Chrysippus discusses the void. There are no other references to *On Parts*. See Appendix II in *SVF* 3, 200.

[34] See Wachsmuth, 1,106,18 and 1,105,26, in texts (b) and (e) above.

[35] See Long and Sedley, vol. 1, 304 and 305.

3. Marcus Aurelius on Time

As we have seen, usually the Stoic theory of time is read as a single theory of time, although one with a few loose ends not fully explained. However we can also see, especially in the testimony of Plutarch, that it might not be unreasonable to see two distinct conceptions of time in the ancient evidence, one with an extended present that belongs and another with a durationless instant separating past and future. But there is nothing to suggest that the Stoics held on to two distinct readings of time as part of one theory and nor is there any evidence to suggest that two such readings were referred to by the terms *aiôn* and *chronos*. Indeed, *chronos* is simply 'time', so what we have been examining thus far is simply the Stoic theory of *chronos*, although the philosophical position that we have uncovered is usually read as one that is close to what Deleuze calls *aiôn*.

---

[36] See *e.g.* Goldschmidt, *Le système stoïcien et l'idée de temps*, 37; J. M. Rist, *Stoic Philosophy* (Cambridge: Cambridge University Press, 1969), 278; P. Hadot, *The Inner Citadel: The Meditations of Marcus Aurelius*, trans. M. Chase (Cambridge, MA: Harvard University Press, 1998), 136; J. Brunschwig, 'Stoic Metaphysics', in B. Inwood, ed., *The Cambridge Companion to The Stoics* (Cambridge: Cambridge University Press, 2003), 206-32, at 215; Sorabji, *Time, Creation, and the Continuum*, 22.

If *chronos* is simply 'time' then what about *aiôn*? This might be straightforwardly translated as 'eternity', although depending upon the context it is also sometimes rendered as 'time'. In the standard collection of the fragments of the early Stoics *aiôn* appears just once, in an obscure etymological observation reported by Varro, who says that Chrysippus defined *aiôn* ('eternity') as *aei on* ('always existing') – if something is eternal it exists always.[37] In short, there is no explicit early Stoic discussion of *aiôn* in the surviving evidence. If we want to find this term in Stoic texts we must move forward some four hundred years from Chrysippus to Marcus Aurelius.[38] In Marcus's *Meditations* there are 21 instances of *aiôn* and it is from Marcus that Victor Goldschmidt takes the term in his discussion of Stoic time, a discussion upon which Deleuze's account of the Stoic theory of time is based.

Goldschmidt argues that there are indeed two conceptions of time in Chrysippus, the extended present that belongs and the infinite past-future separated by the durationless instant, but Goldschmidt suggests that Chrysippus was negligent when it came to terminology. However, that failure was rectified much later by Marcus, who used the term *aiôn* to refer to the infinite time of past-future. In support of this claim Goldschmidt cites *Meditations* 4.3, in which *aiôn* is conjoined with *apeiros*:[39]

---

[37] See Varro, *De Lingua Latina* 6.2 (*SVF* 2.163): 'Aevum ab aetate omnium annorum (hinc aeviternum, quod factum est aeternum): quod Graeci *aiona*, id ait Chrysippus esse *aei on*.'

[38] For Marcus Aurelius I have used the editions by C. R. Haines, *The Communings with Himself of Marcus Aurelius Antoninus* (London: Heinemann, 1916), A. S. L. Farquharson, *The Meditations of the Emperor Marcus Antoninus*, 2 vols (Oxford: Clarendon Press, 1944), and J. Dalfen, *Marci Aurelii Antonini Ad Se Ipsum Libri XII* (Leipzig: Teubner, 1987), the last of which contains a complete Index Verborum.

> Shall mere glory distract you? Look at the swiftness of the oblivion of all men; the gulf of infinite eternity (*apeirou aiônos*), behind and before; the hollowness of applause, the fickleness and folly of those who seem to speak well of you, and the narrow room in which it is confined. This should make you pause. For the entire earth is a point (*stigmê*) in space, and how small a corner thereof is this your dwelling place, and how few and paltry those who will sing your praises here.[40]

However, Goldschmidt fails to note *Meditations* 2.14 and 10.31, in which *apeiros* is conjoined with *chronos*:

> Always remember, then, these two things: one, that all things from everlasting are of the same kind, and are in rotation; and it matters nothing whether it be for a hundred years or for two hundred or for an infinite time (*en tôi apeirôi chronôi*) that a man shall behold the same spectacle; the other, that the longest-lived and the soonest to die have an equal loss; for it is the present alone of which either will be deprived, since (as we saw) this is all he has and a man does not lose what he has not got.[41]

> For in this way you will continually see that man's life is smoke and nothingness, especially if you remind yourself that what has once changed will be no more in infinite time (*en tôi apeirôi chronôi*).[42]

---

[39] Goldschmidt, *Le système stoïcien et l'idée de temps*, 39. See also É. Alliez, 'Aiôn', in B. Cassin, ed., *Vocabulaire européen des Philosophies* (Paris: Le Robert / Seuil, 2004), 44-52, at 45, who cites the same text for the same thesis.

[40] *Meditations* 4.3; translation by Farquharson, modified. Farquharson translates *apeirou aiônos* as 'endless time'; Haines has 'infinite time'. Clearly neither thinks that a contrast between *aiôn* and *chronos* is implied here.

[41] *Meditations* 2.14; translation by Farquharson.

[42] *Meditations* 10.31; translation by Farquharson.

These other passages indicate that Marcus was not using *aiôn* as a technical term to refer to time conceived as infinitely extending into the past and future. Indeed, a careful reading of the 21 instances of *aiôn* and the 31 instances of *chronos* in the *Meditations* makes clear that Marcus uses neither term in any technical sense to refer to a specific conception of time.[43] As we can see from the passages above, Marcus is keen to stress how small a portion of time each of us is allotted compared with the infinite expanse of time, in order to highlight the paltry insignificance of human life, but there is no evidence to suggest a philosophical theory about the nature of time. In these passages Marcus uses the terms *aiôn* and *chronos* synonymously and interchangeably;[44] elsewhere he does use them to draw a contrast between the *chronos* of a human life and the *aiôn* of the cosmos, but again this is merely to draw a contrast between the limited amount of time allotted to each human life and the infinite time of which it is an insignificant part.[45] As we have seen, *chronos* is also used to refer to that same infinite time.[46]

At this point I want to turn to Pierre Hadot's reading of Marcus Aurelius, which involves one of the few explicit discussions of Goldschmidt's thesis.[47] In the *Meditations*,

[43] For *aiôn* see *Meditations* 2.12, 4.3, 4.21, 4.43, 4.50, 5.24, 5.32, 6.15, 6.36, 6.59, 7.10, 7.19, 7.70, 9.28, 9.32, 9.35, 10.5, 10.17, 11.1, 12.7, 12.32; for *chronos* see 1.17, 2.4, 2.14, 2.17, 3.7, 3.11, 4.6, 4.32, 4.48, 5.10, 6.15, 6.18, 6.23, 6.25, 6.36, 6.49, 7.29, 7.35, 7.46, 8.5, 8.7, 8.11, 8.44, 9.14, 9.25, 10.1, 10.17, 10.31, 12.3, 12.18, 12.35.

[44] Compare *Meditations* 2.14, 4.3, and 10.31, cited above. See also 10.17 where they are used synonymously and where Farquharson translates both as 'Time'.

[45] For *chronos* as a finite human lifespan see *e.g.* *Meditations* 2.4, 2.17, 3.7, 4.48, 6.49, 7.46.

[46] For *chronos* as infinite time see *e.g.* *Meditations* 2.14, 10.17, 10.31.

[47] See Hadot, *The Inner Citadel*, esp. 131-7.

Hadot argues, there is a specific attitude towards the present, a concern with focusing one's attention on the present moment. Hadot relates this to the early Stoic theory of time, and quotes Stobaeus (text (b) above). What we find in this report are 'two diametrically opposed conceptions of the present',[48] Hadot suggests: on the one hand the present is merely a limit between past and future, without any extension; on the other hand the present does have a certain duration, reflecting the intention and attention of the individual subject. Rather than try to reconcile these two opposed conceptions of the present, Hadot draws a parallel with the philosophy of Henri Bergson who, in a lecture originally delivered in Oxford in 1911, drew a distinction between the present as a mathematical instant and the present as a certain duration or extension determined by one's attention.[49] For Bergson, the present conceived as a mathematical instant is a pure abstraction without any real existence, unable to constitute part of time for all the reasons outlined by Aristotle. The present that we experience, by contrast, has 'a certain interval of duration':

> Our consciousness tells us that when we speak of our present we are thinking of a certain interval of duration. What duration? It is impossible to fix it exactly, as it is something rather elusive. My present, at this moment, is the sentence I am pronouncing. But this is so because I want to limit the field of my attention to my sentence. This attention is something that

---

[48] Hadot, *The Inner Citadel*, 135. Note also the summary in his *What is Ancient Philosophy?*, trans. M. Chase (Cambridge, MA: Harvard University Press, 2002), 192.

[49] See Hadot, *The Inner Citadel*, 136. Bergson's Oxford lecture was first published in *La Perception du Changement: Conférences faites a l'Université d'Oxford, les 26 et 27 mai 1911* (Oxford: Clarendon Press, 1911), reprinted in H. Bergson, *La Pensée et le mouvant* (Paris: Félix Alcan, 1934), 143-76, and translated in *The Creative Mind*, trans. M. L. Andison (New York: Philosophical Library, 1946), 153-86.

> can be made longer or shorter, like the interval between the two points of a compass.[50]

For Bergson this interval can be expanded or contracted by one's attention, and even expanded so far as to include a substantial portion of one's past. But as soon as we stop paying attention to a particular moment it falls into the past and no longer forms part of our present. Thus the distinction between past and present for Bergson is fluid and dependent upon one's level of attention. In the light of both Marcus's focus on the present moment and Bergson's prioritization of lived duration over mathematical abstraction, Hadot understands Chrysippus's extended present not as a specious pre-philosophical present that evaporates before our very eyes when submitted to philosophical analysis, but rather as a lived present that truly 'belongs' (*huparchein*) to us. When Marcus exhorts us to focus our attention on the present moment he is referring to this extended present, Hadot suggests, and by adjusting our attention we can also expand or contract this extended present along the lines outlined by Bergson.

According to Hadot, Goldschmidt claimed that, for Marcus, this extended present could contract right down to an instant without duration.[51] Hadot rejects this reading of Marcus. He also rejects the claim that, when discussing eternity (*aiôn*), Marcus is conceiving the present as a durationless limit. On the contrary, he is highlighting the limited extension of the present compared with the infinities of past and future. Although Marcus in places describes the present as a point,[52] the context makes clear that this is to emphasize its relative smallness rather than its non-existence. Marcus's term *stigma*, sometimes translated as 'point', is a pin-prick or a mark rather than a mathematical limit.[53] It has a size, albeit a small one. For Marcus, according to Hadot, the present is always the extended lived present. Goldschmidt's attribution of a durationless instant to Marcus reflects his attempt to find a theory of infinite past-future in the *Meditations* and connect it with the evidence for the early Stoa which, as we have seen, does not stand up to close scrutiny.

---

[50] Bergson, *La Pensée et le mouvant*, 168-9; *The Creative Mind*, 178-9.

[51] See Hadot, *The Inner Citadel*, 137, and Goldschmidt, *Le système stoïcien et l'idée de temps*, 195.

According to Hadot's Bergsonian reading, then, there are indeed two distinct Stoic conceptions of the present moment: the first is the durationless mathematical limit or instant conceived by Chrysippus and the second is the extended (expandable and contractible) present meditated upon by Marcus.

Chrysippus:

instant

← infinite past … | … infinite future →

Marcus Aurelius:

(…(…(…(extended present)…)…)…)

Figure 5. Hadot on Chrysippus and Marcus Aurelius

---

[52] See *e.g. Meditations* 4.3, cited above, and 6.36: *pan to enestôs tou chronou stigmê tou aiônos*, which Farquharson translates as 'every instant of time, a pin-prick of eternity'.

[53] However, Aristotle does use this term to refer to a mathematical limit; see *e.g. Physics* 4.13, 222a14-17.

Turning Goldschmidt's claim on its head, according to Hadot it is Chrysippus who is the theorist of unlimited *aiôn*, while Marcus is the theorist of the extended present of *chronos*.

4. TWO APPROACHES TO THE PRESENT MOMENT: BERGSON AND JAMES

So far we have seen Anglo-American scholars dismiss the extended present as specious and French scholars affirm the extended present as primary. While some of the former turn to William James for philosophical inspiration, some of the latter turn to Henri Bergson. As both Bergson and James have been brought into the discussion by these scholars of Stoicism, it may be instructive to consider briefly the relationship between their two positions.[54] This should help us to clarify the difference between Hadot's reading of the Stoic theory of time and the reading dominant in the English-language scholarship.

It is well known that Bergson and James corresponded, met, and had great respect for each other's work.[55] They developed their dual theories of time independently of one another but they do share a striking structural similarity.[56] James in particular often stressed his philosophical proximity to Bergson.[57] Proximity, however, is not identity. In fact, it would be more accurate to say that their two theories are diametrically opposed to one another, one being the reversal of the other. Bergson and James share a position involving two conceptions of the present moment: an extended present of duration on the one hand and a conceptual mathematical limit between past and future on the other. For Bergson, it is the extended present of duration that truly exists, while the conceptual instant between past and future is a mere confusion that cannot grasp the reality of time. For James, by contrast, the extended present is a specious present, a pre-philosophical everyday confusion that should be replaced with the scientific concept of the extensionless instant.[58] (These at least are their opening positions, as I understand them; James may well have amended his position later after discovering Bergson's philosophy.)[59] Both agree that the extended present is our primary experience, but – initially at least – they differ as to its value. James, for instance draws upon psychological studies that try to measure the extended present, and he suggests a maximum duration of 12 seconds. One suspects that Bergson would not have been impressed by such attempts. Indeed, Bergson would have rejected the very phrase 'extended present' to describe his concept of 'duration', for it involves an implicit spatialization of time which is precisely what his theory is trying to overcome. The thought of trying to measure duration simply misses his point.[60]

---

[54] One should also note Sambursky's appeal to Whitehead in his account of the Stoic theory of time. In particular, he cites Whitehead's distinction between a moment and a duration. See S. Sambursky, *Physics of the Stoics* (London: Routledge & Kegan Paul, 1959), 105.

[55] See R. B. Perry, *The Thought and Character of William James*, 2 vols (London: Oxford University Press, 1935), 599-636, which also reproduces their correspondence.

[56] Bergson's position was first outlined in H. Bergson, *Essai sur les données immédiates de la conscience* (Paris: Félix Alcan, 1889), James's in his 1890 work *The Principles of Psychology*. For a rejection of the claim that there was any influence one way or the other see Perry *The Thought and Character of William James*, 599-600.

---

[57] See in particular James's 'Bergson and his Critique of Intellectualism' in W. James, *A Pluralistic Universe* (London: Longmans, Green, and Co., 1909), 225-73. Bergson also wrote on James; see Bergson, *La Pensée et le mouvant*, 239-51 (translated in *The Creative Mind*, 248-60), first published as the preface to the French translation of James's *Pragmatism*.

[58] See James, *The Principles of Psychology*, esp. 608-10. James borrows the phrase 'specious present' from E. R. Clay.

[59] See *e.g.* James, *A Pluralistic Universe*, 235: 'all these abstract concepts are but as flowers gathered, they are only moments dipped out from the stream of time, snap-shots taken, as by a kinetoscopic camera, at a life that in its original coming is continuous'.

As one can see, an appeal to Bergson or to James when trying to reconstruct the Stoic theory of time will imply quite different attitudes towards the extended present, the conceptual instant, and the relationship between the two. It is precisely this relationship that is central to understanding Deleuze's account of *aiôn* and *chronos*. However, an appeal to either James or Bergson when trying to comprehend the Stoic position runs the risk of anachronism.

5. A Stoic Theory?

We should now be in a position to answer the question whether Deleuze's theory of *aiôn* and *chronos* is really an ancient Stoic theory of time. In the light of our discussion a number of points should be clear. Firstly, there is no explicit ancient Stoic theory of *aiôn* and *chronos* and the word *aiôn* is nowhere used in Stoic texts as a technical term within a philosophical theory of time, whether one looks at the doxography for the early Stoics or at a late Stoic text such as the *Meditations* of Marcus Aurelius. Secondly, although scholars have attempted to construct a single theory of time out of the evidence for the early Stoics, tensions remain, and it *is* possible to read within the evidence two distinct conceptions of time. However, the evidence is far too thin to attribute to the early Stoa a twofold theory of time, and the tensions may equally be explained in terms of a development of the Stoic position over a period of time. Thirdly, Marcus Aurelius is concerned with the notion of an extended present and this does contrast with the durationless instant attributed to Chrysippus by modern scholarship. However these two conceptions of the present moment, corresponding to Deleuze's *chronos* and *aiôn* respectively, come from philosophers separated by four hundred years and there is no evidence to suggest that they should be taken together as parts of an explicitly dual theory of time.

---

[60] Later, James may well have agreed with this: the phrase 'specious present' appears in James's 1890 *Principles of Psychology* but it is absent from his 1909 essay on Bergson which contains nothing to suggest that James disagreed with Bergson on this point.

As we have also seen, Deleuze is dependent upon the work of Victor Goldschmidt. Notwithstanding Hadot's criticisms of Goldschmidt, which I think are well founded,[61] Goldschmidt and Hadot share a broadly Bergsonian reading of the ancient Stoics on time in which there are two distinct conceptions of the present moment. In contrast to the Jamesian readings of the English-language scholarship in which the extended present is dismissed as specious, both Goldschmidt and Hadot affirm the reality of the extended present. One can see why the Bergsonian Deleuze would be attracted to the Stoic theory of time when presented in such Bergsonian terms.[62] However, *contra* Goldschmidt, it is to Chrysippus (and not Marcus) that we must turn to find what Deleuze calls the Stoic theory of *aiôn* and it is with Marcus that we shall find the extended present of *chronos*. Whether any ancient Stoic actually held both of these conceptions at once, as a dual theory of time, is a matter about which we must ultimately suspend judgement. There is certainly no evidence to confirm that the theory of *aiôn* and *chronos* made famous by Deleuze was in fact a Stoic theory.

---

[61] I agree with Hadot's criticism of Goldschmidt over the interpretation of Marcus Aurelius. However, do not accept all of Hadot's account of the Stoic theory of time, which, with regard to Chrysippus, does not do justice to the tensions in the surviving evidence. On the basis of the meagre evidence available to us, I would suggest that Plutarch's charge of inconsistency is well founded. But before we praise Plutarch too much we must also remember that our evidence has in part been shaped by Plutarch's own selective quotations from Chrysippus, no doubt informed by his own polemical agenda. On this final point see G. Boys-Stones, 'Plutarch on *koinos logos*: Towards an Architecture of the *de Stoicorum repugnantiis*', *Oxford Studies in Ancient Philosophy* 16 (1998), 299-329.

[62] It is worth noting that Deleuze uses very Bergsonain descriptions in his account of the Stoic theory of time, calling *chronos* the 'living present' and *aiôn* a 'being of reason' (see *e.g. LS* 80/63).

It should be borne in mind that Deleuze made no pretensions to be an expert in ancient philosophy, and this is equally clear from his account of Stoic incorporeals.[63] Nevertheless, it is necessary to be clear about the differences between the Deleuzian and Stoic theories of time if we are to grasp the significance of either of them.[64] The theory of *aiôn* and *chronos* is an interesting element in Deleuze's philosophy that takes its inspiration from a speculative reading of the ancient Stoics, but it is not an ancient Stoic theory.

As I acknowledged at the outset, this relatively minor scholarly point does not claim to raise any philosophical objections to the use that Deleuze makes of this dual theory of time. The same may be said about his confusions regarding the Stoic theory of incorporeals. But it is ironic that it is these aspects of Deleuze's engagement with the Stoics that have become best known. Deleuze's supposedly Stoic ontology in *The Logic of Sense* is not really Stoic at all. By contrast, his comments on Stoic ethics in the same book, although based upon an equally brief acquaintance, are much closer to the spirit of ancient Stoicism.[65] Both Marcus Aurelius and Epictetus would have welcomed Deleuze's statement that 'Stoic ethics […] consist of willing the event as such' and that the ultimate task of ethics is 'not to be unworthy of what happens to us'.[66] It is in the realm of ethics, and not ontology, that Deleuze comes closest to Stoicism.

---

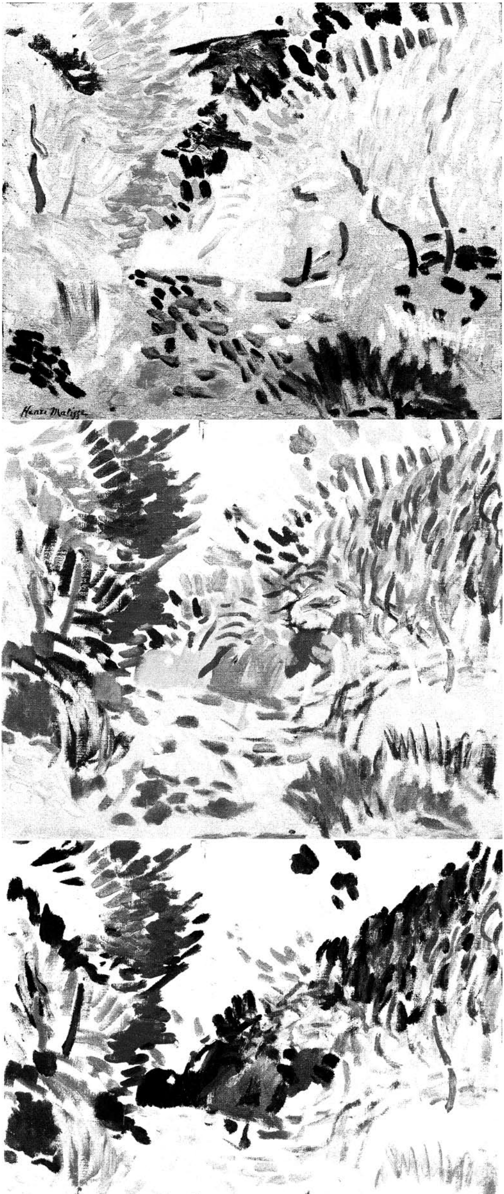
[63] On Deleuze's misreading of Stoic incorporeals see n.4 above. For a discussion of his methodological approach to the history of philosophy see J. Sellars, 'Gilles Deleuze and the History of Philosophy', *British Journal for the History of Philosophy* 15/3 (2007), 551-60.

[64] For a similar point see Mengue, 'Aiôn / Chronos', 45.

---

[65] This claim has been elaborated at greater length in Sellars 'An Ethics of the Event: Deleuze's Stoicism' (cited in n.1 above).

[66] *LS* 168/143 and 174/149.



Henri Matisse

Matisse-Thought and the Strict Quantitative Ordering of Fauvism[1]

Éric Alliez and Jean-Claude Bonne

The revolution inaugurated in painting by Matisse during his 'Fauvist' period of 1905-6 consisted in substituting for the traditional qualitative conception of painting, subordinated to the representation of (the forms of) things and/or the exposition of the medium, a rigorous, intensive conception for which the reciprocal differential quantities of colours are *their qualities, no longer being covered or mediated by phenomenal qualities in whose service their creative power had hitherto been placed. The intensity of colours, which Matisse pushed to its full extent, will fuel the expansiveness of the canvas, energising it from within, ultimately taking it beyond its limits, in other words beyond the Canvas-Form of painting. But this could only be achieved through a 'strict quantitative ordering' at odds with any post-romantic understanding of Fauvism, and implying a rigorous new constructivist conception of expression. An appreciation of Matisse's experimental practice during this period allows a new understanding of the significance of Fauvism for his later work; whilst also reaffirming the philosophical pertinence of a Nietzschean-Deleuzian thinking of intensity and extensity, the qualitative and the quantitative.*

THE QUANTITATIVE FOUNDATION OF THE QUALITATIVE

For Matisse, decorativity implies that *colour only exists qua constructive expression of the relation of forces* between colours. Furthermore, the *relation of quantity* between coloured surfaces would then constitute the *quality* of colour. In the case of a painting which, like his, employs pure (unmixed) pigments, Matisse's formula – '[…] even colour can only be a creation' – only makes sense in envisaging the quantitative determination of the quality of colours[2] – A quantitative creation which seizes hold of the totality of the construction of the painting through the '*all-over*' *organisation of colour* ('this *whole* [*ensemble*] the painting constitutes').[3] 'Organisation of forces – colours are forces'; 'to organise sensations'; 'organisation of his brain' … Matisse comes back continually to this: 'painting requires organisation'.[4] *Organisation is the Matissean name for composition*, for the *global composition* which 'is modified along with the surface to be covered'[5] and consequently is no longer, qua creation in the making, that *classical design* (*disegno*) that would project an *idea* onto an inert matter. Idealist (Italian, Latin) ideation is replaced by the announcement of the materialist idea of the medium, an idea excluding 'preconceived forms' (Derain); an idea whose proper logic is that of the quantitative working of the surface by its freed forces, freely organised in the *all-over conception.* But it is the same Matisse who writes, in his 'Notes of a Painter': 'For me, all is in the conception. It is thus necessary to have, from the very start, a clear vision of the whole [*l'ensemble*].'[6] For, as opposed to the pre-visionary idea of the *study*, this envisaging of the whole is none other than the 'consciousness of the forces that one employs', as one proceeds, 'driven by an idea that one does not truly know except in so far as it develops with the growth [*la marche*] of the painting.'[7] Far from being any sort of 'reportage' of a mental image, its necessity is a *function* of the impossibility of a difference/différance of the conception from its *realisation* (a Cézannian term if ever there was one, to which the painter of Aix opposed the *esprit littérateur*). Or once again: in the absence 'of rupture between thought and the creative act',[8] conception is of importance only inasmuch as it *surfaces* in a continuous becoming. This processual materialism is antipodeal to the post-romantic exasperation to which the Fauvist 'movement' has been reduced. Matisse does not even balk at evoking a *strict quantitative ordering* in a formula which constitutes, in our view, his most technical definition of Fauvism: 'At the time of the "Fauves", what constituted the *strict ordering of our paintings was that the quantity of colour was its quality*.'[9] In what Matisse calls 'expression', a Nietzschean intuition of the greatest purity will always animate Fauvism: The intuition that *quality is nothing other than the difference of quantity which corresponds to it in each force in relation to all other forces*;[10] the intuition that unity can only make sense in the relational domain of the multiplicity of forces in terms of *the organisation of their mutual play*; the intuition of the liberatory function of art qua *destruction* of every type of ulterior world (the artist as 'spokesman for the "essence" of things', the 'telephone to the beyond');[11] and the *construction of a physiology of aesthetics,*[12] grounding itself *quantitatively* upon the forces of the universe, so as to extract from chaos the *varieties of a composition.* It is this *principle of immanence* which continually refers the 'Fauves' back to Nietzsche, offering his philosophy an alternative to the antagonism between romanticism and classicism which the thinker of the Great Midday sought to redefine by recusing 'most resolutely the classical method'.[13] To borrow from Deleuze and Guattari: Fauvism 'is not chaos but a *composition of chaos* that yields the vision or sensation, so that it constitutes, as Joyce says, a chaosmos, a composed chaos – *neither foreseen nor preconceived*'. If it 'takes up arms against chaos, it is in order to *borrow weapons from it that it turns against opinion*, the better to defeat it with tried and tested arms'.[14] (This 'composition of chaos' echoing the *organisation of chaos* put forward by Nietzsche at the end of the second *Untimely Meditation* – '*das Chaos* […] *zu organizieren*'.) In the 1907 interview which Appollinaire, persuaded by Goldberg, succeeded in obtaining with Matisse despite the reticence of the latter, who held the poet for a poor art-critic, we find the formula: 'To order a chaos, that is creation'.[15] Directed against that 'opinion' which had begun by sealing the marriage between romanticism and impressionism, and then that of symbolism with a purportedly 'natural' classicism,[16] the strictness of the ordering indicated by Matisse also implies a rupture with every type of

whole of the second part, 'The genesis of classical formalism'). In the introduction, the author quite rightly posits that 'Far […] from representing a brutal and massive force, the greatest will to power is a power of organisation and thus of the simplification of the original chaos of the universe. Beyond this minimal definition aimed at serving his own philosophical and aesthetic categories, classicism thus means nothing to Nietzsche'.

[14] *What is Philosophy?*, 204 (emphasis ours).

[15] *La Phalange* no. 2, December 1907, reprinted in EPA, 56; unlike other formulas, this is not given in inverted commas, as a citation of a remark of Matisse's but it does seem to correspond to his thought. On the circumstances of this interview, see H. Spurling, *The Unknown Matisse: Volume 1 - A Life of Henri Matisse 1869-1908* (London:Hamish Hamilton, 1998), 415-7.

[16] Nietzsche already noted, in this fragment republished in *The Will to Power* (Trans. W. Kaufman and R.J. Hollingdale, ed. W. Kaufman, New York:Vintage, 1968), 447-8 (§849): 'One believed that classicism was a kind of naturalness! […] The romantics in Germany do *not* protest against classicism, but against reason, enlightenment, taste, the eighteenth century'.

transcendental or spiritualist psychology wedded to the 'language of forms and colours'.

It will be objected that Matisse, in his interview with Tériade, says 'at the time of the "Fauves"' – to which we will answer: Yes, because the quantitative equation crystallises the *trans-historical* dimension of this continued revolution which, in Matisse's words, sees Fauvism at the 'base of everything'. With the principle '*1cm^2 of blue is not as blue as a square metre of the same blue*',[17] Fauvism is inscribed at the base, as the fundament of a *scienza nova* of colour, composing through its differences of quantity a rigorous processual machine of 'requalification' of the world that *exceeds the art-world.* For it does not announce the same thing as Gauguin did when he said to Cézanne: '*A kilo of green is more green than half a kilo*.'[18] For Matisse, the substitution of surface for weight implies a radical rejection of all metaphorisation of quantity, as a result of the severance of all ties with the symbolism of colour: the intensity of colour depends upon a regime *at once superficial and relative* from which every 'in-itself' has been banished – even one *weightily* carried to saturation-point. From this point of view, despite the debt owing to Gauguin, the painter of flat colour planes, for escaping 'the tyranny of Divisionism',[19] Matisse will affirm that 'the basis of Gauguin's work and that of my own, are not the same', discerning the essential point: 'Gauguin cannot be counted among the Fauves, for he lacks a construction of space by means of colour, which latter he employs as an expression of feeling.'[20] Matisse is rather hard on Gauguin – for the latter had indeed also *constructed* space by means of colour. But it must be admitted that this construction plays more upon a qualitative sentiment of colour than upon the quantitative – in other words upon the sentiment of the vital force immanent to colour. This judgment clearly confirms, then, that for Matisse there is a clear difference between vital expressivity and psychological expressionism, since he explicitly opposes himself to the idea of colour as 'expressive of feeling', even though he sometimes formulates his own conception of colour in precisely these terms![21] Thus Matisse sets himself up against a sentimentalism of colour to which is attributed a shared but internally-conflictual symbolism running 'from Eugène Delacroix to neo-impressionism', up to Kandinsky's 'spiritual turn' – a sentimentalism which takes on the cast of a regression or counter-revolution. As Nietzsche wrote: 'We are enemies of *sentimental emotions*.'[22]

[17] Remark by Matisse, reported by Aragon in *Henri Matisse, roman* (Paris: Gallimard, 1998), 830; EPA 129 n95 (emphasis ours).

[18] 'In a golden book I have seen at the house of Marie Gloannec, at Pont-Aven,' specifies Matisse (EPA 129 n95). On this problematic attribution, see Yve-Alain Bois' scrupulous analysis, in 'Matisse and "Arche-Drawing"', *op cit.* 36-9.

[19] Matisse will confide: '[…] fundamentally Gauguin was more answerable than the neo-impressionists for making me take a step in my own direction' (EPA 95 n43).

The summer of 1905 spent in Collioure (in the Eastern

---

[20] H. Matisse, remark collected respectively by G. Duthuit, *Les Fauves* (Paris:Michelon 2006), and Russell Warren Howe, 'Half an hour with H.M.', *Apollo*, February 1949 (EPA 95 and 94 n43). We cite once more Matisse's phrase concerning Gauguin, reported by Escholier, where it is difficult not to hear the echo of symbolism: "I instinctively fled his *already fixed* theory' (EPA 95).

[21] For example, in 'Notes of a Painter', 1908, he writes: 'My choice of colours does not rest upon any scientific theory: it is based on observation, on feeling, on the experience of my sensibility', EPA, 48 *sq*. (but this passage is significantly followed by a first formulation of the quantitative principle, *cf*. *infra*.)

[22] Nietzsche, *Will to Power*, 448 (§850 'The nihilism of artists').

Pyrenees) in the company of Derain, is a period of disquiet and feverish research, leading in diverse and sometimes contradictory directions, very much in Matisse's manner.[23] But Collioure is also the moment when Matisse will begin to experiment with the new, and no longer with the contemporary. The exploratory character of this period translates into products of very heterogeneous appearance, as can be seen by a superficial comparison of *Paysage à Collioure* and *La Moulade*, *Collioure*, both dating from that summer. The first painting is highly vibratory and effervescent, with explosive coloured patches, hatched brushstrokes, large coloured spots [*pastilles*]: it has a more animated and disruptive character than the other. The second has an entirely different texture, produced through the assemblage of taut surfaces, better circumscribed and more homogeneous, even if we also find here discontinuous brushstrokes, in short strips. These two aspects might be considered as symptomatic of two components – one destructive, the other constructive – traditionally associated with Fauvism. But we will see that these components come as a pair and in fact are both to be found in each of the two paintings, as indeed in all his Fauve paintings.

It is true that during the period in question, the liberation in colour of its (vital) energy sometimes takes on an appearance that was deemed disorderly and violent. To face this violence of colour that he had already tested and exploited before the Fauve summer (for example during his 1898 sojourn in Corsica) and to try to control it without renouncing its intensity, Matisse had sought in 1904 (but this was not the first time) a solution by way of neo-impressionism, and certain paintings from Collioure still bear the mark of this solution. But he was soon to discover that Divisionism, by parcelling out colour, destroyed its force. To shake off the yoke of the past and the present alike was indeed to imply a 'destructive' effect, one that would even be qualified as 'chaotic'.[24] It is true that, in certain works, Matisse goes further than all who came before him in challenging the representational conception of colour and of line. The various impressionisms did not go so far as to question radically an optical or symbolic *finality* of the image internal to their paintings, even if they displayed a strong pictoriality quite free from illusionism. But alongside, and intertwined with, this 'destructive' aspect, what also came to light at Collioure was a 'constructive' aspect founding the *maximum* expressive power of colours upon the global quantitative organisation of their relations of forces in such a way that they did not mutually diminish each other. ('An avalanche of colours remains without force. Colour only attains its full expression when it is organised.')[25] Certainly, the constructive stakes of the quantitative are not yet formulated as such at Collioure, but certain canvases are already distinguished by its being (experimentally) taken seriously into account. This must, in any case, have been clear enough to Matisse for him to maintain, retrospectively, that 'at the time of the "Fauves", what constituted the strict ordering of our works, was that the quantity of colour was its quality', a formula already cited, but which must be linked to what follows it, because here Matisse adds a further important specification: 'It had to be right [*juste*] from all points of view. That was what was opportune at the time.'[26] To speak of paintings from the period of historical Fauvism (1905-1906) in terms of a *strict quantitative ordering* will seem surprising to many. Yve-Alain Bois, who so rightly brought into strong relief the importance of the quantitative in Matisse, does not recognise its true employment in painting (after its discovery in the line of the woodcuts of 1906) until after this period, from *Bonheur de vivre* in winter 1905-1906.[27] But he agrees that, despite the *eclecticism* of the Fauve summer and even of the beginning of 1906, 'the most important canvases [of that period] are […] those in which the equation quantity = quality was being sought, before being isolated in the woodcuts', even if this equation as yet only concerned limited parts of the paintings and not their overall construction.[28] Rather than suggest that Matisse is researching something but that he does not know what, we prefer to say that Matisse utilises

---

[23] Indeed, as Phillipe Dagen says: 'Between 1895 and 1905, from twenty-five to thirty-five years old, he dedicated ten years to recapitulating in an exhaustive and methodical manner the modern pictorial styles that had appeared between 1874 and the moment when he set to work.' And, having enumerated them (impressionism, Gauguinism, neo-impressionism, Cézannism, japonism …), the author concludes: 'With subjects chosen with regard to the effects they allow him to experiment with, Matisse reviews references and models, sometimes taking literal inspiration from them, sometimes combining them into strange, mixed forms of painting.' P. Dagen, *Le Peintre, le poète, le sauvage. Les voies du primitivisme dans l'art français*, (Paris:Flammarion 1998), 8.

---

[24] One finds this adjective used by Matisse historians precisely with regard to *Paysage à Collioure*.

[26] 'Visite à Henri Matisse', interview with Tériade, EPA 98-9, emphasis ours (Matisse then explains that this leads to a simplification of forms).

[27] This is the thesis first formulated by Yve-Alain Bois in 'Matisse and "Arche-Drawing"', *op.cit.*, 53: 'According to my hypothesis, *Le Bonheur de vivre* marks at once the end of Fauvism and the birth of the 'Matisse system'; a thesis reprised in 'L'aveuglement', in *Henri Matisse 1904-1917*, exhibition catalogue, 42.

[28] Bois, 'Matisse and "Arche-Drawing"', *op.cit.*, 52.

practically and deliberately (but without yet formulating it) the equation quantity = quality as a *research programme*, and that the object of his experimentation is the possible ways in which this equation might be applied. It is not the object of an exclusive choice, because it is still competing with other solutions. It is therefore not stabilised: all of which results in an eclecticism which, for our part, we would qualify as quite methodical. But it is in this equation that Matisse was to recognise, in the aftermath of a lengthy period of practice, the positive contribution of Fauvism, once its fecundity had been verified and recognised through effects that would have been impossible to anticipate. Such is our hypothesis, but there can be no *a priori* decision on this debate. It is through a 'strict' analysis of the complete 'ordering' of certain paintings that we can put to the test the exactitude of Matisse's assertion *as regards Fauvism itself*. Unless this can be demonstrated, we would have to maintain that Matisse misunderstood himself completely with regard to the nature of his own paintings from the time of the Fauves, and that he is the victim of a very curious retrospective illusion with regard to a crucial aspect of his work. It remains to discover the precise meaning of this equation.

THE INTENSIVE AND THE EXTENSIVE

We will start from the first explicit presentation. A first concern with the *general quantitative adjustment* of at least certain of the qualities of colours appears in 'Notes of a Painter', written in 1907-8. The passage is interesting in that Matisse opposes himself on this point to neo-impressionism, with which he had had to break after having experimented with it. 'Inspired by certain pages of Delacroix's, an artist like Signac becomes preoccupied with complementary colours, and a theoretical knowledge of them leads him to employ, here or there, this or that tone.'[29] That is, Signac makes simple local applications of a general principle that is purely qualitative because thought, and applied, from an exclusively theoretical point of view (as established by Chevreul). For example, the contrast in itself between red and green – naturally, of one particular green and one particular red, but as if their coupling had a purely qualitative identity independently of their quantity.[30] Signac does indeed think (complementary) colours in terms of relations, but simply qualitative relations, quantity – for example the division (the 'mechanical' division, Matisse says) of brushstrokes into regular units – intervening only as one of the several optical qualities of colour. To which Matisse opposes *his practice* of colour: 'For myself, I seek simply to use colours that render my sensation.' Matisse therefore does not start from principle ('we have nothing to do with laws');[31] he observes and follows the singular expressive-vital 'growth' [*«la marche»*] of colours within his painting. The setting of colours is internally governed, without being (tightly) subordinated to a form (which would give it a qualitative identity as colour *of* that form or that figure) or to a symbolism (which would act upon it in the same way). Because – and this is stated directly – 'there is *a necessary proportion of tones* [whose pursuit] can lead me to modify the form of a figure [which latter tends to impose 'its' form on the colour] or to transform my composition. As long as I have not obtained [this proportion] *for all the parts, I seek it, and I continue my*

[29] H. Matisse, 'Notes', EPA 49.

[30] Matisse will say of the neo-impressionist conception, in an interview with Rayssiguier on 5 February 1949: 'it is too narrow: blue, red, green, yellow, *according to the quality between them*'. In H. Matisse, M.-A. Couturier, L.-B. Rayssiuguier, *La Chappelle de Vence. Journal d'une création* (ed. M. Billot, Paris: Cerf, 1993), 141: italics ours.

[31] In response to a question from Russell Warren Howe on complementaries ('Half an hour with Matisse', EPA 49 n14).

work. Then, there comes a moment when *all parts have found their definitive relations*, and from then on, it would be impossible for me to retouch anything in the painting without entirely remaking it' (italics ours). What exactly is to be understood by the 'proportion of tones'? Signac, in his manifesto, means 'by *hue* the quality of a colour [in other words its chromaticity] and by *tone* the degree of saturation and luminosity of a hue', whilst recognising that the two words are often employed the other way around.[32] So perhaps the word 'tone' here captures for Matisse these two *intensive* qualities of colours – unless it is simply a synonym for colour, as might be suggested by the way the word is used in the preceding phrase and by the context more generally.[33] Nonetheless, the notion of proportion implies, in any case, the idea of *quantitative relations* (which takes us beyond the pure quality of Signac's 'hue').

But what precisely is the 'quantity' of colour? One could, indeed one must, understand it in two senses, as both extensive – quantity of surface (of 'hue', if you like) – and as intensive – the force of saturation and luminosity (of 'tone'). Thus a double process is put into play here, or rather a double dimension of the process which Matisse does not make explicit, doubtless because the two aspects are indissociable, thus lending a certain ambiguity to his formulae. It is fitting to remove this ambiguity. For Matisse sometimes says that quantity *is* quality, and sometimes that it is what *gives* quality – which is not the same thing. Could it be that these two different ways of formulating the quantitative principle correspond to these two different ways of understanding quantity?

---

[32] P. Signac, *D'Eugène Delacroix au néo-impressionisme* [1899] (republished Paris: Hermann, 1978), 35n.; note that Signac's 'tone' conflates saturation and what we call luminosity.

[33] In favour of this identity, this formula: 'A mere tone is just a colour; two tones together is an accord, it is life. A colour counts for nothing apart from its accord with its neighbour' (cited by Gaston Diehl in *Henri Matisse* (Paris: NEF, 1970) EPA 67 n41.

In first place, the intensive quantity – the force – of colours varies for Matisse with their reciprocal extensive quantity. The most famous statement of this principle – the statement that '1cm^2 of blue is not as blue as a square metre of the same blue' – is wholly theoretical in so far as it abstracts from the relations between a colour and its 'neighbours'; now, since the latter can change, a colour is able to change in intensity and thus in quality (as the result of a change of contrast, for example) without its 'surface quantity' being modified. (To re-establish an equivalent intensive relation one or other, or both, of the quantities would have, in turn, to be modified). It is intensive quantity alone, but qua differential, that must be said to *be the quality* of the colour, according to the most radical formula of the equation quantity = quality which Matisse formulates *precisely* with regard to Fauvism. The intensive, or difference of force of colour, constitutes its entire quality for Matisse (following the Deleuzian argument: 'each intensity [...] reveal[s] the properly qualitative content of quality' in expressing the difference in quantity).[34] The intensive is *ontologically* and *operationally* primary in that the extensive results from the relations of forces with each another (Deleuze again: 'Everywhere intensity is primary in relation to organic extensions').[35] This is what Matisse's *oeuvre* demonstrates, in so far as extension (figures) and space (where they take place) appear in it not as given in and through forms, but as *resultants* (to use a word of Derain's) of a moment of *the equilibrium of the forces of colours*. What Matisse seeks are ‘energetic and harmonious relations’[36] – *harmony* (that commonplace in art discourse, whose sense he also displaces) must be understood in Matisse as that decorative or *all-over* character which, precisely, gives a work its *equilibrium,* which must be made through, and with, the ‘mutual impact’ of colours.[37] Thus, extensive differences must be regulated as a function of the intensive differential: the painter who ‘wants to give an *expressive* character *to the uniting of many colour surfaces*’ must take into account ‘pure colour, *with its intensity, its reactions on neighbouring quantities*’ – this is the ‘difficult task’ of the painter. Even if the intensive has naturally always been in play in painting to some degree or other, it is Matisse’s Fauvism which operated a systematic and thus wholly affirmative laying-bare of *chromatic energy* (in so far as it is no longer mediated) – an expressivity which is the sensible reason of vitalism, and without which Fauvism would lose its principle of immanence. Or, once more: colours *are not* identitarian qualities, as in a ‘representative’ system which necessarily cuts off forms from the *differential of forces* constituting the material basis of their production, in order to make appear the identity which stabilises them and allows them to be recognised in their *formal, and thus structural, differences* (resemblance is the law of quality as *form of representation*). When intensive difference is submitted to representation and thus to identity, 'quality then comes to cover over intensity', as Deleuze concludes in the pages where he takes colour as his example.[38] When, on the other hand, representation is submitted to the differential of forces, the field of their confrontation overwhelms formal differences, *bearing and sweeping them away* into its chaosmosis. See *Paysage à Collioure*: Non-identitarian, the colours are nonetheless energetic individuating differentiations whose singularities always enter into relations of forces amongst themselves; relations of forces which assure their resonance and/or their internal/external expansivity in this intense field of individuation which the canvas *is*, which it *becomes*. Every individuating force thus affirms itself in communicating immediately with others in an 'aesthetic of intensities' whose processual, *chaosmic* immanence might be called the 'implicated art of intensive quantities' in so far as it ex-plicates the 'fluent world of Dionysus' in restoring the difference of intensity as vital being of the sensible.[39]

---

[34] *Difference and Repetition*, 222.

[35] *Ibid*, 251.

---

[36] This expression is found in a letter from Matisse to Pierre Gaut, director of Établissements Linel, 25 March 1946, reproduced by Antoinette Rezé-Huré, ‘Une lettre de Matisse à Pierre Gaut’ (*Cahiers du Musée national d’art moderne* 84, 13 July 1984), 28 (Établissements Linel were responsible for finding the typographical inks for the reproduction of the plates of *Jazz*).

[37] ‘For me, colour is a force. My paintings are composed of four or five colours which collide with each other, giving sensations of energy.’ – A statement, around 1942, by the ever-‘Fauvist’ Matisse to Pierre Courthion (reported in P. Courthion, ‘Avec Matisse et Bonnard’, in *D’une palette à l’autre. Mémoires d’un critique d’art* [Geneva: La Baconnière Arts, 2004] 173).

We will not say of *extensive quantity* that it *is*, properly speaking, the quality of colour, but only that it actualises it and, in this sense, produces its *intensive quantity* (in other words its differential quality). This is what can be surmised from formulas such as: 'The quantities being different, their quality changes: when colours are employed quite overtly, it is their relations of quantity which *make* their quality'; or again: 'it is the proportion of colour which *gives* [the stained-glass windows of Chartres Cathedral] their quality'[40] – remember that the 'Notes of a Painter' spoke of 'a necessary proportion of tones'. Given that *to make* and *to give* do not mean *to be*, these formulas are probably better understood as alluding to extension, or 'quantity of surface', but one might also suppose them to refer to quantity in general, in so far as it always implies the intensive and the extensive.[41] As far as the extension of colours is concerned, above all the point must be made that, apart from the quantity of surface properly speaking (its area), this extension also refers to *spatial qualities* capable of affecting the intensity of colours, and so these must be taken into account in regulating their reciprocal extension. It is probably this aspect of the quantitative that Matisse is addressing when, after having declared that 'at the time of the "Fauves", what constituted the strict ordering of our works, was that the quantity of colour was its quality', he adds, as will be remembered, this crucial specification: 'It must be *right from all points of view*', and insists: 'That was what was opportune at the time' (emphasis ours). Matisse does not enumerate 'all the points of view' according to which the intensive quantity of colour (and necessarily the extensive also) must 'be right' – that is to say strictly ordered/arranged – because, since they are innumerable, an exhaustive inventory cannot be made of them. We must be content with suggesting the principal ones. Intensive quantities are to be adjusted not only as a function of the proportions of their sizes (brushstrokes, colour-patches, masses of colour, larger surfaces …) but also of their forms (precise or indeterminate, figurative or not, with clear or degraded borders, compacted or explosive …); of their placement in the field (peripheral, central, high, low …); of their density (thick or transparent …); of their texture (smooth flatness, worked matter, homogeneous, fluid or taut …); of their orientation (uni- or multidirectional, centrifugal, centripetal …); of the frequency and modes of distribution of these different surfaces (unicity, multiplicity, aleatory or ordered rhythmicity …), not forgetting the chromatic interactions (complementarity, simultaneous contrasts …). Thus, to take this last case, the theoretical quality of contrasting complementary colours varies practically, for Matisse, with the reciprocal quantities of these colours.[42] The (intensive) quality of colours is thus not only a function of their 'surface quantity',[43] as certain formulae suggest,[44] it must also be *quantitatively adjusted* as a function of other spatial properties of the surfaces. It is in these conditions that the *quantitative ordering* of *all* of the painting imposes itself as the discovery of Fauvism. The question of the quantitative is thus complex and cannot be the object of a finite calculation but only of an open evaluation on the part of a spectator who must, as far as possible, estimate it according to the 'points of view' implicated in the construction of the painting (as so many *factors forcibly entering, entering into force*). All the forms of the quantitative being, practically, mutually intricated and indissociable, we can speak globally of the quantitative (as does Matisse), leaving implicit what it comprises of the extensive and the intensive.

---

[38] *See Difference and Repetition*, 245: '[A] multiplicity such as that of colour is constituted by the virtual coexistence of relations between genetic or differential elements of a particular order. These relations are actualised in qualitatively distinct colours, while their distinctive points are incarnated in distinct extensities which correspond to these qualities'.

[39] *Ibid*. See also in *Difference and Repetition* the Nietzschean conclusion of the chapter 'Asymmetrical Synthesis of the Sensible'.

---

[40] Respectively, H. Matisse, letter to Alexandre Romm, January 1934 (correspondence published in the catalogue of the exhibition *Henri Matisse*, Moscow, Musée des Beaux-Arts Pouchkine, and Leningrad, Musée de l'Ermitage, 1969), EPA 146, and 'Notes on colour', EPA 206.

[41] The formula concerning the stained-glass of Chartres is immediately preceded in 'Notes on Colour' by a formula that we have cited above on 'pure colour with its intensity, its reactions on neighbouring quantities'.

---

[42] In 'Notes of a Painter' Matisse writes, after the declaration on the proportion of tones: 'In reality, I hold that the very theory of complementaries is not absolute' because 'one could […] push back the frontiers of the theory of colours as currently accepted', EPA 49.

[43] EPA 149.

[44] This is also, if we understand correctly, what is suggested in Yve-Alain Bois' 'Matisse and "Arche-Drawing"', *op.cit.*

No longer being directly mediated by an external finality (which, on the contrary, is now but a medium in the service of energetic vitalism), the qualities of colours no longer depend on anything but their relations of quantity (intensive and extensive). It is true that the relatively large and homogeneous flat colour plane renders particularly sensible the importance of the quantity of surface in the force of colour. This is what Matisse will practice in the compositions of large coloured surfaces *after* the epoch of historical Fauvism. He will indeed declare with regard to the works of 1909-10 that put into play only a few colours, in large surfaces: 'When I undertook *La Danse* and the Moscow *Musique* – I was determined to put the colours into surfaces, without nuances […] What seemed to me *essential was the surface quantity of colours*.'[45] That this was what *then* appeared essential to him does not at all mean that he was indifferent to the other 'points of view' (to realise this one need only look at a reproduction of his paintings in inverse: 'the surface quantity' being unchanged, all the relations of colours are completely upset). This point, naturally, is decisive for the treatment of the question of the quantitative in the Fauve period, during which Matisse does not yet resort, or very little (in any case not systematically) to significantly large flat colour planes, because he has not yet come fully to realise the importance of the extensive. Still, the accumulation of enlarged brushstrokes coming together as a mass through an identity of colour, the coloured patches and, *a fortiori*, the more considerable applications of colour, already function as (quantities of) *surfaces*, in the twofold sense of marks which are given as literally applied to (the surface of) the canvas, and which maintain a certain surface area there (*qua* isolated elements or multiplicities of variable density).[46] The spacing of brushstrokes is certainly not the best way to *intensify* colour *to the maximum*, but it is already a way to *quantify it differentially*. If one refuses to recognise the (intensive) quantification of colours in a 'strict ordering' (necessarily including the extensive) as the contribution of Fauvism, on the pretext that the colours do not yet occupy a sufficient 'surface quantity' (a 'large' flat colour plane), it is because one wrongly identifies intensive quantity and *maximal* intensification. Furthermore, a response must be given to this rather absurd question: 'at what level of "surface quantity" does/will a surface begin to function quantitatively (= qualitatively)?' It appears to us decidedly problematic to say that the Matisse-system does not begin until *Le Bonheur de vivre*. The quantitative equation functions already in Fauvism, and from Fauvism onward, because colour has no other finality in principle apart from its immanent vital expressivity; it is this alone that *imposes* this equation, not the extensive as such. Will not Matisse-Thought have demonstrated anew a tremendous historical *and* theoretical pertinence, in its formulation of the quantitative principle 'at the time of the "Fauves"'? For this formulation implies that it can only be a question of intensive quantity – as that which *is* the quality of colour – and not particularly of its (large) extensive quantity, whose importance had not yet been either truly recognised or isolated, and which was thus *implicitly* numbered amongst 'all the points of view' according to which 'quantity' must be adjusted. To *intensify* intensity, thereby to assure a greater grasp of the quantitative on the qualitative, Matisse was to be led, *at the end of the Fauve experimentation and as one of its direct developments*, to simplify and to augment the dimensions of the colour surfaces, and thus to *make explicit* the importance of extensive quantity. This will certainly be an important evolution in the conception of the quantitative equation, but not at all a rupture marking its appearance.

---

[45] H. Matisse, letter to Alexandre Romm, October 1934, EPA 149 (emphasis ours).

---

[46] Even though in 1912, the following remark of Matisse's already makes sense for the epoch of historical Fauvism: 'Do not apply different little brushstrokes, but masses, because it is through quantity, through mass, that your tone acts in your painting.' Reported by Marcel Sembat in his 'Cahiers noirs', date of 29 April 1912. Taken up again in *Matisse-Sembat, Correspondence. Une Amitié artistique et politique, 1904-1922*, ed. C. Phéline and M. Baréty (Lausanne:La Bibliothèque des Arts, 2004), 170.

With regard to the epistemological importance of the quantitative factor in the interpretation of human phenomena at the end of the nineteenth century and the beginning of the twentieth, one cannot but bring together the name of Nietzsche with that of Freud who, very early on, will aim to 'discover what form the theory of mental functioning assumes when one introduces the notion of quantity into it, a sort of economy of nervous forces'. In developing this economy, the psychic processes will be linked to displacements, investments and discharges of a 'quantum of affect', which 'corresponds to the drive in so far as the latter is detached from representation and finds an expression adequate to its quantity in processes which become sensible to us as affects';[47] with the result that the affect will be defined as 'the qualitative expression of the quantity of drive energy and of its variations'.[48] The quantitative principle which thus brings together Matisse and Freud is all the more striking in that the latter has no affiliation with the intellectual references of the former.

Let us return to the question(ing) of form, to which our reflection here belongs. It can easily be seen that the quantitative principle which founds the Matissean aesthetic as an energetics of colour implies that form should be thought in terms of active, not static, surface, and still less in a purely linear fashion. If a painting really obeys a system of *all-over* construction in which the forms do not isolate themselves one from another by detaching themselves from the ground, their qualities do not belong to intrinsic properties of contours, but are rather relative to the relations of (intensive and extensive) quantities of coloured surfaces, relations within which the line that reciprocally delimits these surfaces is itself also held. Naturally, the colours present qualities that are not directly quantitative, in other words not intrinsically vital – representational, expressionist, pictorial qualities … Matisse always strives to treat them also in terms of relations of force, so that they might participate in a constructive fashion in his vitalism. Which necessarily implies treating them quantitatively, since the quality of a force lies in its quantity relative to another. ‘The essence of force is its quantitative difference from other forces, and […] this difference is expressed as the force’s quality’.[49] By bringing together this Nietzschean formula of Deleuze’s with Nietzsche’s own question – ‘To what extent is art immersed in the essence of force?’ – one might measure the proximity of Matisse-Thought to Nietzsche, and risk a (possible) response.

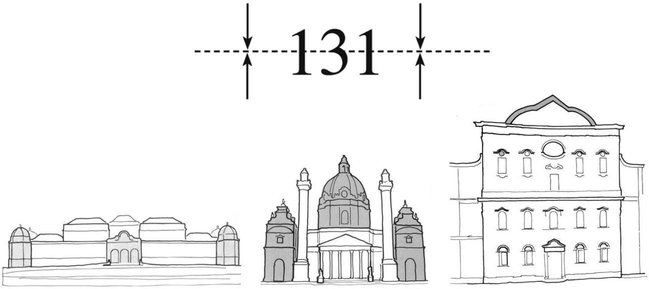
infinitely tiny things differential relations that will make possible an integration of the sum—in other words, a clear and distinguished perception. It is a filter, a selection. Now, on the one hand, I am not always capable of doing so at all times, but only in a particular zone that varies with each monad, and such that, for each monad, the greatest part remains in a state of detached dizziness, undifferentiated, unintegrated, in an absence of accord. All that can be said, to the contrary, is that no part of the world can be taken in the zone of *a* determinable monad, and that does not carry accords produced by this monad. But on the other hand especially, the linkages produced by a monad can be very different. Leibniz's writings clearly guarantee a classification of accords.

It would be wrong to seek a direct transposition of musical chords in the way they are developed in the Baroque; and yet it would also be erroneous to conclude with Leibniz's indifference in respect to the musical model: the question, rather, involves analogy. And we know that Leibniz was always trying to bring it to a new rigor. At its highest degree, a monad produces *major and perfect accords*: these occur where the small solicitations of anxiety, far from disappearing, are integrated in a pleasure that can be continued, prolonged, renewed, multiplied; that can proliferate, be reflexive and attractive for other accords, that give us the force to go further and further. This pleasure is a "felicity" specific to the soul; it is harmonic par excellence, and can even be felt in the midst of the worst sufferings, such as in the joy of martyrs. In this sense the perfect accords are not pauses, but, on the contrary, dynamisms, which can pass into other accords, which can attract them, which can reappear, and which can be infinitely combined.[23] In the second place, we speak of minor accords when the differential relations among the infinitely small parts only allow integrations or instable combinations, simple pleasures that are inverted into their contrary, unless they are attracted by a perfect accord. For, in the third place, integration can be made in pain. That is the specific character of *dissonant accords*, the accord here consisting in preparing and resolving dissonance, as in the double operation of Baroque music. The preparation of dissonance means integrating the half-pains that have been accompanying pleasure, in such ways that the next pain will not occur "contrary to all expectations." Thus the dog was musical when it knew how to integrate the almost imperceptible approach of the enemy, the faint hostile odor and the silent raising of the stick just prior to its receiving the blow.[24] The resolution of dissonance is tantamount to displacing pain, to searching for the major accord with which it is consonant, just as the martyr knows how to do it at the highest point and, in that way, not suppress pain itself, but suppress resonance or resentment, by avoiding passivity, by pursuing the effort to suppress causes, even if the martyr's force of opposition is not attained.[25] All of Leibniz's theory of evil is a method to prepare for and to resolve dissonances in a "universal harmony." A counterexample would be furnished by the damned, whose souls produce a dissonance on a unique note, a breath of vengeance or

Unknown Deleuze

Mehrdad Iravanian



Two ‘unknown Deleuze’*s and one* ‘un’*: an approach to deciphering the collective symmetrical manner of the central page* (*page* 131) *of* The Fold (518 *words*) *– carrying out a logical cartographical composition of abstract topological elements* (*monads, words, etc.*)*. The baroque nature of* 131 *can be distinguished through two references*: *firstly, the central piece* (3) *has an identical architectural form to baroque facades* (*Santa Maria della Pace, Saint Ivo della Sapienza, Sant’Andrea al Quirinale*)*; secondly, the same central piece* (3)*, as surrounded by symmetrical pieces* (1-1)*, manifests the voluptuousness of a curvilinear, growing, unfolding form, immanently symmetrical. As a form,* 131 *presents the elements of symmetrical order of the early baroque.*

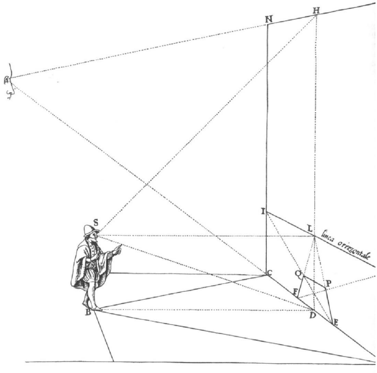
COLLAPSE III, ed. R. Mackay (Falmouth: Urbanomic, November 2007)
ISBN 978-0-9553087-2-0
http://www.urbanomic.com

‘An expression of states and relations which are inflected, which evolves a process shaped by different types of information before, during and after a building is materialized.’ This is how a boogazine – a hybrid type of publication, often employed by architects and combining the heterogeneity and topicality of a magazine with the referential and comprehensive approach of a book – describes the comic-book-like format through which it re-edits an event (*viz.,* any product: building, piece of writing, art object), usually after the event has found the solid ground necessary in order for it to be instituted as an object.

The proper place to seek the unfolded Deleuze is within the collective information that he has processed, not outside the content: the unknown is within.

More precisely, in relation to the subject at issue:
With regard to its sources, *The Fold* diagrams the
unpleating function.

Chapter title: *The New Harmony* – a most appropriate title
for this new arrangement of unread characters.



Apprehension

The following graphitext critically examines this type of processing whilst (1) avoiding the vulgar comic-book tendency toward collage (instead invoking the baroque sense of perpetual development of a term); (2) receding to a lower profile of difference: The dominant modes and techniques of visual literacy are based on creating a relation between (graphical) elements in a grammatical manner – puzzle-solving on a monodimensional surface. It ought to be understood, however, that their effects (the perceived visual production) ultimately take place in the distance between the observer and the work (as related to the monodimension). Control of this space (the inderdimensionality between the observer and the work) can be achieved by influencing the networks of a series of focal points, the difference between the members of which is only a matter of distance (either as color or shape: hue, gradient, saturation, etc.). So that this management of distances between focal points from the observer is another way of creating 'work' – a lesser-known type of visual literacy amongst graphic artists.

Another World

J.-H. Rosny the Elder

ROSNY AND THE SCIENTIFIC FANTASTIC[1]

The pseudonymous J.-H. Rosny (1856-1940) was 'already multiple', even before Belgian brothers Justin and Joseph-Henri Böex subjected him to a belated fissure, thus giving birth to Rosny 'the Younger' and Rosny 'the Elder'. It was Joseph-Henri, 'Rosny the Elder', who would achieve notoriety in the late nineteenth century as one of the group of writers whose 1887 *manifeste du cinq* broke acrimoniously with Zola's naturalism, declaring it a pandering and sterile form.[2] J.-H. Rosny the elder became a prominent literary figure, later presiding over the *Academie Goncourt*

and publishing over 150 books in almost every genre, from historical romance to what he dubbed *le merveilleux scientifique*, in virtue of which he is now recognised as a pioneer of Science Fiction. A minor 'rediscovery' in the 1970s saw his SF stories republished in the original French,[3] with a few being translated for US paperback editions, and a 1981 film of his prehistoric tale *Quest for Fire*, but to this day Rosny's legacy remains undeservedly overshadowed by those of Verne and Wells.

Only Deleuze's patronage saves Rosny from equal obscurity as a philosopher, even though a contemporary placed him in the most exalted company, dedicating a volume saluting a 'philosophical revolution' to 'Bergson, Einstein, le Dantec and Rosny the Elder'.[4] Deleuze was familiar with Rosny's fantastic fiction (a 'naturalism in intensity'),[5] but it is the reference to two key theses of the philosophical work *Les sciences et le pluralisme*[6] that confirm

[4] J. Sageret, *La Révolution Philosophique et la Science*: *Bergson, Einstein, Le Dantec, J.H.Rosny aîné* (Paris: Alcan, 1924).

[5] See *Difference and Repetition* 326-7n. 2.

[6] *Les sciences et le pluralisme* was published in 1922 by Félix Alcan, a publisher who, in the first decades of the twentieth century, assembled a remarkable stable of philosophers of science (Lachelier, Renouvier, Brunschvicg, Bergson, not to mention Gabriel Tarde, Jean Wahl and Michel Souriau, to name only those cited in *Difference and Repetition*) who would exert a profound, if subterranean, influence upon French philosophy for the rest of the century. Alcan's name is attached to a group of authors who, rather than embodying a common ethos, saturated, through a sort of philosophical chromaticism, every philosophical possibility the epoch offered to the field.

The philosophical programme of philosophy of science inaugurated by Lachelier and Boutroux, and later renewed by Cavaillès and Bachelard, was, of course, finally interrupted by the Occupation, subsequently to be obscured by the 'return to the that Rosny's contribution to *Difference and Repetition* was far from marginal:

> (1) Resemblance presupposes difference; it is differences that resemble one another;
>
> (2) Difference alone allows us to conceive of being.[7]

Rosny's book attacks the 'monist' presupposition that science proceeds by annulling differences through a reduction of the heterogeneous and complex to the homogeneous and elementary;[8] and that any dissenting, pluralist position must lead to nothing more than a 'confusionism'.[9] In so far as scientific thought implies simplifications and abstractions, like Bergson, Rosny regards it as continuous with cognition *per se*, and with life as such: Noting that 'each of our senses is constructed so as to

---

concrete' – but continued to operate beneath the surface, as is evident equally from the work of Badiou and Deleuze. See present volume, 35-6n. 90. A particularly clear account of the origins and mutations of this tradition is given by C. Imbert 'La fin d'une période : de Lachelier à Cavaillès et de Boutroux à Bachelard', at http://tlrdoc.free.fr/pages/philosciences.htm.

Alcan was one of the first French publishers to cede editorial control of scholarly journals to the scholars themselves, privileging innovation over tradition. This made Alcan the focal point of a new social network which would later lead to the formation of the *Quadrige* alliance of academic publishers, later PUF. For a detailed analysis of the role of *alcanisme* in the formation of the allied *Presses Universitaire de France* (PUF), and Alcan's impact in French publishing culture and the nascent figure of the intellectual, see V. Tesnière, *Le Quadrige: un siècle d'Édition universitaire, 1860-1968*. (Paris: PUF, 2001).

[7] *Difference and Repetition* 327n. 2.

[8] The most prominent advocate of such a thesis was Emile Meyerson, according to whose anti-positivist nihilistic ontology the underlying principle of science is an elimination leading to a uniform 'void' of absolute identity lacking all qualities. See E. Meyerson, *Identity and Reality* trans. K. Loewenberg (NY: Dover, 1962 – first published in French by Alcan in 1908).

[9] J.-H. Rosny Ainé, *Les sciences et le pluralisme* (Paris: Alcan, 1922), 1.

"neglect" what does not interest it',[10] he takes up Bergson's example of the 'contraction' of light, suggesting that '[i]n the same way' that we 'contract' trillions of vibrations into a single qualitative sensation, 'science continually neglects, totalizes, symbolizes.'[11] But for Rosny this abstraction always exists and acts alongside *experimentation*,[12] which continually puts thought back in touch with the infinite complexity of the real, there to discover new differences, the disequilibria that drive scientific revolutions and refoundations.

Like the process of evolution, the progress of scientific thought constantly wards off a passage to the limit in either direction, to monism or 'confusionism'. But although we cannot therefore do without either the concept of difference or that of resemblance, Rosny claims that the former encompasses the latter: 'the concept of difference, since it is irreducible, radically suppresses the concept of resemblance, whilst the latter does not at all suppress that of plurality.'[13] The pluralist conception subtends the monist one, which tacitly presupposes it, and this, for Rosny, in so far as pluralism, 'the only possible method, the only one that has been implicitly practiced, the only one conforming to intellectual activity issued from instinctive activity'[14] necessarily implies a theory of difference: 'There can be no unity if difference is essential to the constitution of things; but there can be any number of resemblances, resemblances of every order,

"different" resemblances, so to speak, in an indefinitely varied and variable universe';[15] 'we perceive more and more clearly summations of differences, where before we thought we saw resemblances.'[16] Like his contemporary Gabriel Tarde, whose 'differential epistemology' proposed that the infinitesimal and its integration were 'the key to the entire universe',[17] Rosny discovers the magical equivalence 'PLURALISM=MONISM'[18] through the promotion of difference as primary and fathomless; whence the formula repeated in *Difference and Repetition* to illustrate that there is nothing behind difference but difference:

> All (calculable) energy implies factors of the form E – E', in which E and E' themselves conceal factors of the form e – e', and so on indefinitely.[19]

This differential pluralism extends from Rosny's philosophy of science into his science fictions, for if 'experimentation indefinitely dominates speculation' this implies the tantalising fact that 'we only ever know a tiny portion of things in relation to the immensity and diversity of the universe. It makes us see that there exist innumerable series whose existence will never be revealed to our feeble powers of discrimination'.[20] In the final chapter, where Rosny makes this connection explicit, *Les sciences* begins to answer to Deleuze's ideal definition: philosophy becomes truly 'a kind of science fiction', written 'at the frontiers of knowledge',[21] and invoking the central theme of Rosny's fantastic tales: strange alien beings just beyond the reach of our limited knowledge:

> [T]here is no reason why the terrestrial surface, since it is traversed by immense energies, should not have produced organic systems equal in complexity to our own. No more than there is any reason that it might not produce another organic realm once ours has disappeared. My *Xipehuz*, *Moedigen* and *Ferro-Magnetics* are perhaps pale symbols of anterior and future realities.[22]

Indeed, these were already the stakes of Rosny's first SF tale, 1887's *Les Xipehuz*, whose nonorganic aliens announced, as surely as do the 'Moedigen' of 'Another World', the arrival of a non-anthropomorphic SF.

Along with this obsession with radically different orders of living beings, Rosny's rejection of the hubristic aspiration to a unification of knowledge unites him with another writer favoured by Deleuze: The following is Rosny, but it could easily have been written by the American weaver of weird tales H.P. Lovecraft (1890-1937):

> Revolting against our infirmity, if we cannot traverse and dominate the universe, at least we might conceive it. Vain dream of ephemeral beings, whose race will last but an instant in the innumerable succession of phenomena [...] [23]

Both Rosny and Lovecraft drew on contemporary scientific advances, and did not hesitate to extrapolate wildly from them. Both created weird tales in which 'the world of normality hardly ever appears',[24] even as a dramatic foil for preternatural occurrences. Both had a taste for materialism, scientific rationality, and precision that showed through in the meticulous construction of their alien worlds and creatures; both showed a will to estrange the reader with scientifically-plausible abstract-cosmic theses, with creatures that went beyond any biological comprehension but exemplified the most outlandish findings of physics (in Rosny we find creatures that are geometrical constructs of pure energy, helicoidal ferromagnetic forms, fluid, spiral, cones of magnetically-charged matter – all in perfect keeping with Lovecraft's bizarre hexagonal barrels, four-dimensional protoplasms and ineffable yet material presences). Both authors seal this alienation with their weird creatures' unpronounceable names – Rosny's 'Wanawnanabm' and 'Kzamms' for Lovecraft's 'Nyarlathotep' and 'Cthulhu' – and by overegging their tales with weighty adjectival invocations of the noumenal.[25]

---

[24] J.P. Vernier 'The SF of J.H. Rosny the Elder', *Science Fiction Studies*, #6, 2:2, 1975.

[25] 'First of all there are certain words – always the same, always identical, almost piercing, like incantatory fomulae: fearful, formidable, terrible, prodigious, savage, gigantic! […] As if the author had deliberately wanted to define his literary universe, as if he had sought, by resorting to a singular vocabulary, the most accurate adumbration of his real and precise ambitions […]' – Jean-Baptiste Baronian, 'Les Fins et les Manieres', preface to Rosny, *Récits*, 5.

'In this register Lovecraft has never been equalled. One may copy his manner [...] but one can never imagine oneself emulating those passages where he loses all stylistic reserve, where adjectives and adverbs accumulate to the point of exasperation, where he lets loose exclamations of pure delirium [...] [T]his is the true goal of his work. One could even say that the often subtle and elaborate structures of the "major works" have no other purpose apart from preparing the way for passages of stylistic explosion [...] The adjectives and the exclamation marks multiply, the fragments of incantation spring to his mind, his heart is lifted with enthusiasm; he plunges into a true ecstatic delirium [...]' – M. Houellebecq, *H.P.Lovecraft: Against the World, Against Life*, trans. D. Khazeni (NY: Believer Books, 2005). Translation modified).

But as well as the difference in their scientific expertise (Lovecraft, though invariably well-researched, was ever the gentleman-amateur, whereas Rosny was something of a polymath and was in direct contact with the scientific luminaries of his day, including – as Deleuze notes – Marie Curie) the two authors display a marked difference in moral outlook. Although both perceived with utmost clarity the extent to which modern science had dislodged man from the centre of the universe, whilst Lovecraft revelled in repeatedly hammering home man's powerlessness in the face of impersonal cosmic forces (see Houellebecq's suberb account),[26] Rosny maintained a faith in man which survived the ravages of darwinism, atomic physics and relativity.

Both invoke weird and frightening creatures beyond our ken; but whereas in Lovecraft's quasi-Faustian tales an unhealthy taste for science is often to blame for bringing unhappy protagonists into contact with beings they ought to have left well alone, for Rosny these beings can, through the power of scientific thought, be brought within the purview of a positive scientific knowledge, in the process altering our own perception of the universe – a cognitive evolutionism, then, inspired no doubt by the enthusiasm for the mechanisms of adaptation and mutation in Bergson and his contemporaries.

Although Lovecraft and Rosny share a fascination for the seething world of particles and energy and for the apparent impossibility of defining what constitutes a living being, by constantly emphasising man's biological kinship with 'lower' and 'higher' forms of life alike and his consequent interconnectedness with the universe, Rosny finds a paradoxical sort of comfort wholly lacking in Lovecraft's visions of cosmic desolation. This theme of a sort of abstract community is keenly argued throughout Rosny's work: he believes in a sort of primacy of a *structure of life*; and inversely the 'meaning of life', in the higher form of advanced scientific thought, is the search for structure. Rosny's hymns to experimental research – including 'Another World' – are in some sense the inverse of Lovecraft's grim counsel against meddling with the hostile indifference of the physical universe. Perhaps this can be attributed to Rosny's personal involvement with the science that rendered Lovecraft awestruck from afar; Rosny's faith in the human involvement in the fundamental questing impulse of science fending off the Azathothic terror brought on for Lovecraft in contemplating its actual findings:

---

[26] Houellebecq, *op.cit.*

> Modern research, you who have made of the abstract a tool rather than a limit, oh incommensurable spiral – reaching into the depths of the spaces where the human spirit ascends […] [27]

As we know, for Lovecraft, there is no mistaking that this spiral is a *descent* … Furthermore, for Rosny, universal community becomes a link between the everyday world of emotion and sociality, and the arid calculus of exact science; thus suggesting a very definite view of science's positive historical and social import: it is, after all, this intuition of structure common to all life that, in Rosny's *Les Navigateurs de l'infini,* allows a human to fall in love with a six-eyed martian 'of ternary symmetry'![28] The instinct for beauty, an *a priori* for all possible consciousness and recalling the role of purposiveness in Kant's aesthetics, reflects the cosmic dominance of structure, and therefore implies the possibility of bringing the human into harmony with a universe full of uncharted inhuman forms of life. Rosny's touching suggestion – utterly unthinkable for Lovecraft – is that we can even come to empathic terms with 'luminous networks of phosphorescent matter' – as ridiculous as it might seem, perhaps not such a very different sentiment from the spirit that inspired the plaque on the Voyager space probe.

---

[27] Vernier, *op.cit.*

What intervened in between 'Another World' and 'The Mountains of Madness', between the cosmic optimism of diaphanous, playful lifeforms and the absymal horror of tentacular crawling chaos, was the Great War – technological arsenals unleashed in a senseless, implacable and indifferent manner that Lovecraft perhaps saw as a revelation of the very eternal truth of the universe.[29] Nevertheless, Rosny is no mere anti-Lovecraft, any more than he is merely anti-Meyersonian. In fact it is the black romantic Lovecraftian vision of dissolution into confusionist schizophrenic chaos[30] that is the reverse image of the Meyersonian glacial ascent to monolithic identity. Rosny's differential ontology means that his pluralism can affirm both simplification and complexification, in a non-dialectical relation; differentiation and selection together with a univocity that preserves an empathic opening to the cosmic. Seeing no contradiction between an immediate aesthetic apprehension of the universe (beauty) and scientific knowledge (structure), arguing for the equal importance of conceptual reduction and an experimental/experiential immersion, Rosny's work is a unique, lyrical vitalist-structuralist apology for pluralism.

[29] See China Miéville's introduction to H.P. Lovecraft, *At the Mountains of Madness* (NY: Random House, 2005); Note also that 1910 saw the publication of Rosny's *Mort de la Terre*, where the parallel life-forms – this time 'ferromagnetic beings' – finally turn on man, killing off the human race.

[30] See *A Thousand Plateaus*, 73-4, 240, 245, 248.

'Another World' typifies the Rosny narrative arc: an alienated being is reconciled with our world through systematic scientific experimentation, conducted by the sympathetic figure of the curious but prudent and objective Doctor van den Heuvel.[31] A mediation is achieved between 'durations' which would otherwise exist in parallel, unknown to each other; ending in a union which promises more experiments, more differentiations, to come.

---

[31] Note that the protagonist of 'Another World' finds both social acceptance and the scientific expertise necessary to bring him into engagement with the wider world, in the cordial cosmopolitan setting of *the city*, which, for Lovecraft, promised only the horror of pullulating 'shoggothic' masses (see Houllebecq, *op. cit.*).

ANOTHER WORLD

I

I am a native of Gelderland. Our inheritance had dwindled to a few acres of heather and yellow water. Pine trees lined its borders, quivering and rustling with a metallic sound. The farmhouse had hardly any habitable rooms, and was crumbling, stone by stone, in its solitude. We were a clerical family of old, once numerous, now reduced to my parents, my sister and myself.

My destiny, so dark to begin with, has become as wonderful as I could ever have dreamt of: I have met with those who understand me; they have learnt that which I alone amongst men know. But I suffered for such a long time, I despaired, prey to doubt, to the solitude of the soul, which ended up corroding even absolute certainties.

I came into the world with a unique constitution. From the start, I was an object of astonishment. Not that I seemed maladapted: I was, so they told me, more graceful of body and countenance than is normal in a newborn. But I had a most extraordinary complexion, a sort of pale violet hue – very pale, but most definite. In lamplight, especially that of oil-lamps, this tint became even more pale, turning into a peculiar whiteness, like a lily submerged in water. That was, at least, what other people saw: myself, I saw it differently, as I saw differently all objects in the world. For this first peculiarity was to be supplemented with others which would reveal themselves later on.

Although born with all the appearance of good health, I grew very slowly. I was thin, I cried endlessly; at eight months old, no-one had ever seen me smile. They soon began to despair of the prospect of raising me. The doctor from Zwartendam declared that I was stricken with a physiological infirmity: he could recommend no other remedy than a strict regime of hygiene. But this did not prevent my wasting away; it seemed that, day by day, I was just fading away. My father, I believe, was resigned to it, his *amour-propre* – the *amour-propre* of a Dutchman of order and regularity – somewhat injured by the bizarre nature of his child. My mother, quite against the grain, loved me all the more in proportion to my bizarreness, having eventually found the tone of my skin lovable.

Things stayed just so, until a rather simple event came to my rescue: but, just as everything was abnormal for me, this event too was to be an occasion for scandal and fear.

Upon the departure of a servant, to replace her we took on a vigorous young girl from Friesia, full of honesty and enthusiasm for work, but with a weakness for drink. I was entrusted to the new arrival. Seeing me so weak, she came up with the idea of giving me, in secret, a little beer and water mixed with jenever: a remedy, according to her, for all ills.

The most curious thing is that I wasted no time in regaining my full vigour, and that from that time onwards I demonstrated an extraordinary predeliction for alcoholic drink. This fine girl secretly rejoiced, not without a certain relish at the puzzlement of my parents and the doctor. Put on the spot, she finally solved the mystery. My father flew into a violent rage; the doctor railed against superstition and ignorance. Strict orders were given to the servants; and my nurse was sent back to Friesia.

I began to get thinner again, to waste away, to the point where, hearkening only to her love for me, my mother put me back on the regime of beer and jenever. At once, I regained my vigour and vivacity. The experiment was conclusive: alcohol was revealed to be indispensible to my health. My father took it as a humiliation; the doctor took charge of things by arranging for medicinal wines to be brought, and after this my health was excellent: although one would be forgiven for presaging for me a career of drunkenness and debauchery.

A little after this incident, a new anomaly struck those around me. My eyes, which first of all had appeared quite normal, started to become strangely opaque, taking on a calloused appearance, like the hard wingcases of certain beetles. The doctor predicted that I would lose my sight; all the time avowing that the condition seemed absolutely inexplicable to him and that he had never had occasion to study anything remotely similar. Soon the pupil was so amalgamated with the iris that it was impossible to tell the one from the other. It should be remarked, meanwhile, that I was able to look at the sun with no apparent unease. In truth, I was not in the least bit blind – in fact it would have to be admitted in the end that I saw extremely well.

Thus I attained the age of three years. I was, according to the opinion of those of the neighborhood, a little monster. The violet colour of my skin had hardly changed; my eyes were now completely opaque. I spoke poorly and with incredible speed. I was nimble with my hands and well adapted for any movements that demanded more speed than strength. It could not be denied that, if I had had a normal complexion and normal eyes, I would have been graceful and pretty. I showed signs of intelligence, but with certain gaps which those around me could not fathom, especially as – apart from my mother and the Friesian girl – they did not like me at all. For strangers I was an object of curiosity, for my father a continual source of mortification.

If, however, the latter may have nursed hopes of seeing me one day become equal with other men, time served only to dash them. I was to become more and more strange, in my tastes, in my conduct, in my qualities. At six years old, I nourished myself almost uniquely on alcohol. Only very rarely did I take a few mouthfuls of vegetables or fruits. I grew prodigiously fast, I was incredibly thin and light. I mean light in a quite specific sense – something different to merely thin people: I swam with the slightest of effort, I floated like a plank of poplar-wood. My head didn't sink any more than the rest of my body.

I was nimble in proportion to this lightness. I ran as fast as a deer; I leapt over ditches and obstacles which no man would even try to clear. In the blink of an eye, I could climb to the top of a beech-tree; or, what is even more surprising, I could jump right onto the roof of our farmhouse. On the other hand, even the slightest burden exhausted me.

*

All of these, in sum, were only phenomena indicative of a peculiar nature, which would not, on their own, serve to distinguish me or make life hard for me: none of them categorised me outside the bounds of humanity. No doubt I was a monster, but certainly no more than those born with the eyes or ears of an animal, with the head of a calf or of a horse, fins, no eyes or an extra eye, four arms, four legs, or no arms or legs at all. My skin, despite its surprising tint, was near enough to being just a tanned skin; my eyes were not particularly repugnant, despite their opacity. My extreme agility was an asset; my need for alcohol could have passed for a simple vice, the result of a family legacy of drunkenness: in any case, rustic folk like our Friesian servant would see in it only a confirmation of their ideas about the 'potency' of jenever, a particularly acute proof of their tastes. As to the speed of my speech, its volubility, which made it impossible to follow, this might have been mistaken for faults of pronunciation – stuttering, stammering, lisping – common to so many small children. I therefore did not have, properly speaking, any striking traits of monstrosity, even if the whole was extraordinary in its combination: for the most curious aspect of my nature escaped those around me, because none of them could know that my vision differed strangely from normal vision.

If I saw some things less well than others, I also saw a great number of things that others did not see at all. This difference was especially manifest with regard to colours. Everything that is called red, orange, yellow, green, blue, indigo, appeared to me as a more or less dark grey, whereas I perceived violet, and the series of colours beyond it, colours which are nothing at all for normal men. I recognised later on that I could thus distinguish about fifteen colours as dissimilar as, for example, yellow and green – with, of course, an infinity of gradations.

Secondly, transparency does not manifest itself to my eye in the usual way. I saw quite poorly through glass and through water: glass is very densely coloured for me; so is water, noticeably, even when quite shallow. Many so-called diaphanous crystals are more or less opaque to me, and inversely many supposedly opaque bodies are no barrier to my vision at all. In general, I can see through things more often than you; and translucidity, semi-transparence, is so commonplace that I might say that it is, for my eyes, the rule for nature, whereas complete opacity is the exception. Thus it is that I see objects through trees, leaves, the petals of flowers, magnetised iron, coal, *etc.* However, as their thickness varies, these bodies become an obstacle: such as a large tree, water a metre deep, a thick block of coal or of quartz.

Gold, platinum, mercury are black and opaque, ice is blackish. Air and water vapour are transparent, but somewhat coloured, like certain types of steel, certain very pure clays. Clouds do not prevent me from seeing the sun nor the stars. However, I can perceive the clouds suspended in the atmosphere.

This difference between my vision and that of other men was, as I have said, very little remarked upon by those close to me: it was known that I distinguished poorly between colours, that was all; and that is too common a problem to draw much attention. It was without great consequence for the day-to-day proceedings of my life, since I saw the forms of objects the same – and perhaps even more subtly – than most people. The designation of an object by its colour, when meant to differentiate it from another object of the same form, was only a problem if they were new to me. If someone called the colour of one waistcoat blue and that of another red, the real colours in which the waistcoats appeared to me mattered little: blue and red became purely mnemonic terms.

Along these lines, you can well understand that there emerged a certain sort of accord between my colours and the colours of others, and that ultimately it became just as if I saw their colours. But, as I have already written, I perceived red, green, yellow, blue, etc. when they were pure – as are the colours of a prism – as darker or lighter shades of grey; they simply were not colours for me. In nature, where no colour is pure, things are not the same: some substances called green, for example, are for me a certain composite colour;[32] but another substance called green, and which to you looks exactly the same shade as the first, is not at all the same colour for me. You can therefore see that my palette of colours does not correspond to yours: when I agree to call both brass and gold 'yellow', it is a little as if you were to agree to call both a cornflower and a poppy 'red'.

II

If the difference between my vision and normal vision had stopped there, this would, certainly, have been extraordinary enough. It is nothing, however, in comparison to what remains for me to tell you. The world coloured differently, differently transparent and opaque – the faculty to see through the clouds, to see the stars even on the most overcast of nights, of seeing through a wooden partition what is happening in an neighbouring room or outside a house – what is all that, compared to the perception of a LIVING WORLD, of a world of animated beings who move alongside and all around man, without man ever being conscious of it unless he is alerted to them by some sort of immediate contact? What is all that, compared to the revelation that there exists on this earth a fauna other than our fauna, one which does not resemble ours whatsoever, either in form, organisation, or behaviour, nor in the way it is born, grows, and dies? A fauna which lives side-by-side with ours and beyond ours, influences the elements which surround us and is influenced by them, is nourished by these elements, without our ever suspecting their presence. A fauna which – as I will demonstrate – knows nothing of us just as we know nothing of it, and which has developed in complete isolation from us just as we have in complete isolation from it. A living world, with just as much variety as ours, just as significant as ours – and perhaps more so – in terms of its effects on the face of the planet! A kingdom, finally, moving across the oceans, in the atmosphere, in the soil, modifying these oceans, this atmosphere and this soil, in a completely different way than we do, but with an assuredly formidable energy, and in that way acting indirectly upon us and on our destinies! … This, nonetheless, is what I saw, what I see, alone among man and beasts; this is what I have studied fervently for five years, after having spent my childhood merely observing it.

---

[32] And this composite colour, of course, does not contain green, since green is but a shadow for me.

III

Observing it! For as long as I can remember, I instinctively supressed the attraction of this creation so alien to our own. At first I confused it with other living things. Perceiving that no-one else took any notice of its presence, that everyone, on the contrary, seemed utterly indifferent to it, I made no effort to point out its peculiarities. At six years old I knew perfectly how to distinguish it from the plants of the fields, the animals of the farmyard and stable, but I sometimes still confused it with inert phenomena such as fire and light, or the motion of water and clouds. These beings were intangible: when they touched me I felt no sensory effect from their contact. Meanwhile their forms, however highly varied, had the peculiarity of being so thin in one of their three dimensions, that one might compare them to drawn figures, to surfaces, mobile geometrical lines. They traversed all organic bodies; on the other hand, they seemed sometimes to be blocked, entangled in invisible obstacles … But I will describe them later. For now, I want only to indicate, to affirm, the variety of their contours and lines, their almost complete absence of thickness, their impalpability, along with the autonomy of their movements.

*

Around the time of my eighth year, I finally realised definitely that they were just as distinct from atmospheric phenomenon as from the animals of our natural kingdom. Enraptured by this discovery, I tried to express it. I could never succeed in doing so. As well as my speech being nearly completely incomprehensible, as I have said, the extraordinary nature of my vision rendered what I said suspect. No-one would bother to spend the time to decipher my gestures and my phrases, any more than they would be minded to admit that I could see through wooden partitions, however many times I might furnish proofs of so doing. There was, between myself and others, an almost insurmountable barrier.

I fell into discouragement and reverie; I became a sort of solitary child; my presence caused unease – and I could sense it – when in the company of children my own age. I was not exactly a victim, since my speed put me well out of the reach of childhood malice and gave me the means to wreak revenge easily. At the least sign of trouble, I would be far away, leaving the pursuer floundering. No matter what numbers they came in, children could never hope to surround me, much less get a hold of me. It was not even any use to try to grab me by stealth. As weak as I was when it came to bearing a load, my speed was irresistible, and I would escape instantly. I could return unexpectedly and overcome the adversary, or even adversaries, with prompt and sure blows. So they left me alone. They took me at once for an innocent and something of a sorceror, but one whose brand of sorcery was apparently so limited that he deserved scorn. By degrees, I began to live a life apart, insular, meditative, and not completely devoid of peaceful moments. Only the kindness of my mother humanised me, even if, busy most of the day, she found little time for caresses.

IV

I will try to describe summarily several scenes of my tenth year, before making more concrete the preceding explanations.

It is morning. A large lamp lights up the kitchen, a lamp which is a pale yellow for my parents and the servants, very different for me. Breakfast is being served, tea and bread. But I do not take any tea. They just give me a glass of jenever with a raw egg. My mother busies herself tenderly with me; my father questions me. I try to answer him, I slow down my speech; he only understands one syllable here, one there, and shrugs his shoulders.

"He'll never speak! …"

My mother looks at me compassionately, convinced that I am a little simple. The domestic staff and the servants are not even curious any longer about the little violet monster; the Friesian returned to her homeland a long time ago. As for my sister – she is two – she plays around me, and I feel a great fondness for her.

The meal finished, my father goes on his way, along with the servants, and my mother begins to attend to the daily chores. I am in there in the courtyard. The animals gather around. I regard them with interest, I love them. But all around, the other Kingdom shifts and changes and captures me even more: the mysterious domain that I alone know.

On the brown earth, there are various scattered forms; they move, stop, palpitate across the expanse of the ground. They are of many types, differentiated by their shape, their movement, and above all by their behaviours, the contours and the hues of the curves which traverse them. These curves constitute, in sum, the principle of their being and, even as a child, I could see this quite well. Whilst the greater part of their form is dull and greyish, the lines are almost always sparkling. They form very complicated webs, they emanate from centres, they radiate, until they die out, becoming indiscernible. Their hues are innumerable, their curves infinite. These hues vary for one single line, as they do also, but less so, for the whole form.

Taken as a whole, each being is described by a contour, rather irregular but very distinct, by centers of radiation, by multi-coloured, multiply intersecting lines. When it moves, the lines vibrate, oscillate, the centres contract and dilate, whilst the contour hardly varies.

All of this, I saw quite well, already, even if I was incapable of defining it; I was penetrated by an exquisite charm in contemplating the Moedigen.[33] One of them, a colossus ten metres long and almost as wide, passes slowly across the courtyard, with great centres like eagles' wings, interests me greatly and almost frightens me. I spend a moment following it, but then others claim my attention. They are of all sizes: some are no bigger than our most common insects, whereas I have seen some attain more than thirty metres in length. They proceed on the ground only, as if they are attached to solid surfaces. When a material obstacle – a wall, a house – presents itself, they clear it by moulding themselves to its surface, always without any significant modification of their contours. But when the obstacle is of matter that is living or has lived, they pass directly through it: I have seen them thus, a million times, emerging from a tree and under the feet of an animal or a human. They also pass through water, but prefer to remain on the surface.

These terrestrial Moedigen are not the only intangible beings. There is an aerial population, marvellous and splendid, of an incomparable subtlety, variety, and lustre, besides which the most beautiful birds are dreary, slow and heavy. Here again, a contour and some lines. But the bottom is not greyish; it is strangely luminous; it sparkles like the sun, and the lines detach themselves from it in vibrating veins, the centres palpitating violently. The Vuren, as I named them, are more irregular of form than the terrestrial Moedigen, and generally speaking they direct themselves with the aid of rhythmic behaviours, crossings and uncrossings whose nature, in my ignorance, I could not determine and which confounded my imagination.

---

[33] This is the name which I spontaneously gave them during my infancy, and which I have kept for them, even if it does not correspond to any quality or form of these beings.

Meanwhile I had taken my route across a recently-mown lawn: the combat of one Moedig with another drew my attention. These combats are frequent; they intensely excited me. Sometimes, it is a combat between equals; most often the attack of a strong one against a weak (the weak is not necessarily the smallest). In the present case, the weak one, after a summary defense, takes flight, pursued briskly by its aggressor. Despite the speed of their progress, I follow them, and I succeed in not losing sight of them, up to the moment when the battle recommences. They fall on one another, firmly, rigidly even, each one solid against the other. At the shock, their lines phosphoresce, are directed towards the point of contact, their centres blanching and contracting. At first, the struggle remains fairly equal, the weaker expending energy the most intensely, and even succeeding in obtaining a respite from its adversary. It profits from this by fleeing anew, but is rapidly caught up, attacked with force and finally seized upon, that is to say consumed through an opening in the contour of the other. This is precisely what it had sought to avoid, by responding to stronger shocks with less energetic, but more sudden shocks. Now, I see all of its lines vibrating, its centres pulsing despairingly; and, in proportion to this, its lines fading, growing finer, the centres becoming more indistinct. After a few minutes, it is granted its liberty: it moves away slowly, dimly, debilitated. The antagonist, on the contrary, sparkles yet brighter, its lines are more highly coloured, its centres more distinct and more rapid.

This struggle has profoundly moved me; I re-imagine it, I compare it to battles which I have seen sometimes between our animals; I grasp confusedly the fact that the Moedigen, essentially, do not die, or only rarely so; that the victor contents itself with taking energy at the expense of the vanquished.

The morning wears on, it is nearly eight'o'clock; the Zwartendam school will open soon: I make a leap back to the farmhouse, I gather my books, and there I am, amongst my classmates, where no-one divines the profound mysteries which pulsate all around us, where no-one has even the most confused idea of the living things which all humanity traverses and which traverse humanity, with no indication of this mutual penetration.

I am a truly awful scholar. My writing is but a halting trace, unformed, unreadable; my speech remains uncomprehended; my distraction is obvious. The schoolmaster continually cries:

"Karel Ondereet, are you finished watching the flies buzzing around? …"

Alas! Dear master, it is true that I watch the flies buzzing, but how much more my soul follows the mysterious Vuren which move through the room! And what strange sentiments haunt my young soul, in observing everyone else's blindness, and above all yours, grave pastor of minds!

V

The most painful period of my life was from twelve to eighteen years old.

Firstly, my parents tried to send me to college; there I knew only miseries and vexations. At the cost of exhausting difficulties, I was able to express in an almost comprehensible manner the most common things: slowing my syllables with great effort, I spat them out maladroitly and with the accent of a deaf person. But, as soon as it was a question of something more complicated, my speech reverted to its inevitable speed; and once again no-one could hope to follow me. I could not hope therefore to make my progress known orally. On the other hand, my writing was atrocious, my letters squashed up one on top of the other, and, in my impatience, I missed out syllables, words: it was a monstrous gibberish. In any case, writing was for me a torment perhaps even worse than speaking: – of an asphyxiating heaviness and slowness! – If, on occasion, by sheer painful force of will, and sweating great drops, I managed to begin some work, soon I was at the end of my energy and patience, and felt I was about to faint away. So that I preferred the remonstrances of the masters, the punishments, the scorn, to this horrible labour.

Thus, I was almost totally deprived of any means of expression: an object of ridicule, already, because of my skinniness and my bizarre colouring, because of my strange eyes, I now also passed for some sort of idiot. I would have to remove myself from the school, resign myself to being a peasant. The day when my father decided to renounce all hope, he said to me with unaccustomed kindness:

"My poor boy, you see, I have done all I can … all I can! Do not reproach me for your fate!"

I was intensely moved; I cried hot tears: I had never felt with such bitterness my isolation from the world of men. I ventured to embrace my father tenderly; I murmured:

"But still, it isn't true that I'm an imbecile!"

And, in fact, I felt myself superior to those who had been my colleagues. For a while now, my intelligence had taken a remarkable turn. I read, I understood, I did some guesswork, and I had sufficient occasion for meditation, far more than others, in this universe visible to me alone.

My father did not decipher what I said, but he softened to my embrace.

"Poor boy!" he said.

I looked at him; I was in dreadful distress, knowing more than ever that the void between us would never be filled. My mother, by some intuition born of love, saw in that moment that I was not inferior to other boys of my age: she beheld me with great tenderness, mouthing naïve pleasantries from the depths of her being. But I was nonetheless condemned to cease my studies.

Because of my feeble muscular power, they entrusted me with the care of the livestock. I acquitted myself marvellously; I never needed a dog to keep the herds or a foal under control, no stallion was more agile than I.

I lived, then, between the ages of fourteen and seventeen, the solitary life of the shepherd. It suited me more than any other. Given over to observation and contemplation, and also to much reading, my brain never ceased to develop. I compared ceaselessly the double creation I had before my eyes, drawing from this some ideas on the constitution of the universe; I vaguely fabricated hypotheses and systems. If it is true that my thoughts could not have at this time a perfect correlation, did not form a lucid synthesis – for they were the thoughts of an adolescent, uncoordinated, impatient, enthusiastic – they were nevertheless original and fecund. That they were only of value to my unique constitution, I would not deny at all. But not all their force came from this. Without the least pride, I believe I can say that they surpassed appreciably, in subtlety and in logic alike, those of ordinary young people.

They were the sole source of consolation in my sad life of a semi-pariah, without companions, without real communication with those around me, even my beloved mother.

*

At seventeen, life became decidedly unbearable for me. I was sick of dreaming, sick of vegetating in a desert island of thought. I fell into languor and boredom. I spent long hours immobile, disinterested in the whole world, inattentive to everything that happened within my family. What did it matter to me to know things more marvellous than other men, since in any case this knowledge was to die with me? What use to me was the mystery of the living beings, and even of the duality of the two vital systems traversing one another without any knowledge of each other? These things could have intoxicated me, filled me with enthusiasm and ardour, had I been in any way able to teach them or to share them. But what hope of that! Vain and sterile, absurd and miserable, they rather contributed to my perpetual psychic quarantine.

Many times, I dreamt of writing, of setting down, all the same, at the price of continual efforts, some few of my observations. But, since I had left school, I had completely abandoned the pen, and, such a poor writer before, now, even when I applied myself fully, I could barely write the twenty-six letters of the alphabet. If I could have still conceived of some hope, perhaps I might have persisted! But who would take my miserable lucubrations seriously anyhow? Where was the reader who would not think me insane? Or the sage who would not dismiss me with disdain or irony? What purpose, then, could I adduce for such a vain task, such a tiresome devotion – something like the obligation, for an ordinary man, to carve his thoughts on tables of marble, with a hammer and chisel! Any writing of mine would have to be stenographic – and what's more, a stenography more rapid than the usual!

Thus I had not the courage to write, but nevertheless I hoped fervently for some unknown, some happy and singular stroke of destiny. It seemed to me that there must exist, in some corner of the earth, impartial, lucid, rigorous minds, able to study me, to understand me, to be able to speak with me and to communicate my great secret to others. But where might these people be? And what hope did I have of ever meeting them?

And I fell again into a vast melancholy, into desires for immobility and annihilation. For a whole autumn, I despaired of the universe. I languished in a vegetative state, from which I only emerged to give voice to great laments followed by dolorous revolts.

I became thin again, to the point of becoming fantastically so. The people of my village called me, ironically, Den Heyligen Gheest, the Holy Ghost. My silhouette trembled like that of the old poplars, light as a reflection, and, at the same time, I attained the stature of a giant.

Slowly, a project was born. Since my life was sacrificed, since none of my days held any appeal to me, since all was darkness and bitterness to me, why stagnate in inactivity? Even supposing that no soul existed which could respond to mine, surely it was worthwhile to make the effort to convince myself of it. At least it was worth quitting this morose land, going to find the great cities of scientists and philosophers. Wasn't I, after all, an object of curiosity? Before even calling attention to my superhuman cognitions, could I not excite the desire to study my person? Weren't the physical aspects of my being alone worthy of analysis: my sight, the extreme quickness of my movements and the peculiarity of my nutrition?

The more I reviewed these thoughts, the more it seemed reasonable to hope, and the more my resolution grew. The day arrived when it became absolutely firm, and I revealed it to my parents. Neither of them really understood, but both ended by ceding after repeated insistences: I obtained the means to take myself to Amsterdam, and to return should the outcome be unfavourable to me.

I left one morning.

VI

From Zwartendam to Amsterdam it is around a hundred kilometres. I made this distance easily in two hours, with no particular incident apart from the extreme surprise of those coming and going at seeing me run with such speed, and some gatherings at the outskirts of small towns and large market-towns which I passed. To be sure of my route, I addressed myself to two or three solitary old people. My sense of direction, which is excellent, did the rest.

It was around nine'o'clock when I got to Amsterdam. I entered resolutely into the great city, I walked the length of its beautiful dreamy canals where the commercial flotillas live. I did not attract as much attention as I had expected to. I walked fast, amongst people who were busy, suffering here and there the gibes of a few young urchins. I decided not to stop, however. I walked around the city a little in every direction, until finally I resolved to enter a cabaret, on one of the quays of the Herengracht. The location was peaceful; the magnificent canal stretched out, full of life, between fresh rows of trees; and amidst the Moedigen which I saw circulating on the banks, I seemed to see a new species. After a moment of indecision, I crossed the threshold of the cabaret and, addressing myself to the patron, as slowly as I could manage, I asked him to be so good as to tell me the way to a hospital.

The host looked at me with a mixture of stupor, defiance and curiosity, took his big pipe from his mouth and put it back, many times, then finished by saying:

"You are from the colonies, no doubt?"

As it was perfectly useless to contradict him, I responded:

"That's right! …"

He seemed enchanted by his own perspicacity; he set me a new question:

"Perhaps you come from that part of Borneo where no-one has yet set foot?"

"The very same! …"

I had spoken too fast: he opened his eyes wide.

"The very same!" I repeated more slowly.

The host smiled with satisfaction:

"You can't speak Dutch too well, eh? … Well, it's a hospital you want … You're ill, are you?"

"Yes …"

Some customers had approached. The rumour was already going round that I was a cannibal from Borneo; nevertheless, they looked at me more with curiosity than antipathy. Some men ran up from the road. I became nervous, disquieted. Nevertheless I kept a straight face, and said, coughing:

"I'm very ill!"

"Just like the monkeys from that country," offered a very fat dutchman cordially, "the Netherlands kill them!"

"What funny skin!" said another.

"And how does he see?" asked a third, indicating my eyes.

The circle drew nearer, enveloping me with a hundred curious looks, with new arrivals constantly entering the room.

"How tall he is!"

It is true that I was taller than the tallest of them by a head.

"And thin!"

"He doesn't seem to be getting much nourishment, this cannibal!"

None of the voices seemed particularly malevolent. A few sympathetic individuals protected me:

"Don't push him like that, he's ill!"

"Come on, friend, courage!" said the big fat man, seeing my nervousness. "I'll take you to a hospital myself."

He took me by the arm; he set about pushing through the crowd, shouting:

"Make room for an invalid!"

The dutch crowd were not particularly fierce: they let us pass, but tagged along after us. We strode along the canal, followed by a compact multitude; with people crying:

"It's a cannibal from Borneo!"

*

Finally, we got to the hospital. It was visiting time. They led me to an intern, a young man with blue glasses, who received me sullenly. My companion said to him:

"It's a savage from the colonies."

"What, a savage!" cried the other.

He removed his glasses to look at me. For a moment his surprise held him immobile. He asked me brusquely:

"Can you see?"

"I see very well …"

I had spoken too fast.

"It's his accent!" said the fat man proudly. "Say it again, friend!"

I repeated it, and made myself understood.

"They are not human eyes …" murmured the student. "And the colour! … Is that the colour of your race?"

I said, making a terrible effort to slow myself down:

"I've come to be seen by a scientist!"

"You're not ill then?"

"No!"

"And you're from Borneo?"

"No!"

"Where are you from then?"

"From Zwartendam, near Duisbourg!"

"So why did your companion claim that you were from Borneo?"

"I didn't want to contradict him … "

"And you want to see a scientist?"

"Yes."

"Why?"

"To be studied."

"To make some money?"

"No, nothing like that."

"You're not a poor person? A beggar?"

"No!"

"Why are you so keen to be studied?"

"My constitution … "

But I had again, despite my efforts, spoken too fast. I had to repeat myself.

"Are you sure that you can see me?" he demanded, looking fixedly at me. "Your eyes are like callouses … "

"I see very well."

And, moving right and left, I swiftly picked up objects, put them down, through them into the air and caught them.

"Extraordinary!" continued the young man.

His voice now softer, almost amicable, filled me with hope:

"Listen," he said finally, "I think doctor Van den Heuvel might well be interested in your case … I'll go and tell him about it. You wait in the next room … And, about …. I forgot … you're not ill, then?"

"Not at all."

"Good. Come on … in here … the doctor won't be long … "

I found myself seated amongst monsters conserved in alcohol: foetuses, children of bestial form, colossal frogs, vaguely anthropomorphic reptiles.

This is definitely, I thought to myself, my waiting-room … Aren't I a candidate for one of these formaldehyde sepulchres?

VII

When doctor Van den Heuvel appeared, emotion overwhelmed me: I had the frisson of the promised land, the joy of touching it, the fear of being banished from it. The doctor, a large bald man, with a powerful analytical gaze, a soft but stubborn mouth, examined me in silence, and, as with everybody, my excessive thinness, my great height, my encircled eyes, my violet complexion, were causes for astonishment.

"You say that you would like to be studied?" he asked finally.

I responded with great force, almost violence:

"Yes!"

He smiled in an approving manner, and then posed the customary question:

"Do you see well with those eyes?"

"Very well … I can even see through trees and clouds …"

But I had spoken too quickly. He shot me a disquieted glance. I reiterated, sweating great drops:

"I can even see through trees and clouds …"

"Really! That would be extraordinary … Well then! What do you see beyond that door … there?"

He indicated to me a long-disused door.

"A large glass-fronted bookcase … a large carved table …"

"Really!" he repeated, stupefied.

My chest expanded, a profound peace descended upon my soul.

The scientist remained in silence for a few seconds, then:

"You speak with great difficulty."

"Otherwise I speak too fast! … I can't speak slowly."

"Alright, then tell me something in your usual voice."

I recounted then the episode of my entry into Amsterdam. He listened with great attention, with an air of intelligence and observation that I had never before encountered from my own people. He did not understand anything I said, but he displayed great sagacity in his analysis:

"If I'm not mistaken … you pronounce between fifteen and twenty syllables per second, that is to say three or four times more than the human ear can perceive. Your voice, also, is far more acute than anything I have heard from a human voice. Your gestures, excessively rapid, correspond to your speech … Your constitution is probably as a whole more rapid than ours."

"I run," I said, "quicker than a greyhound … I write …"

"Ah!" he interrupted. "Let's see your writing …"

I scribbled a few words down on a blotter he handed to me, the first quite legible, the others more and more mixed-up, abbreviated:

"Perfect!" he said, and a certain pleasure was mixed with his astonishment. "I really think that I can count myself lucky in making your acquaintance. It will assuredly be most interesting to study you."

"It's my most dear, my only desire!"

"And mine, obviously … Science … "

He appeared preoccupied, in a reverie; he finally said:

"If only we could find some more easy way to communicate … "

He paced the room from end to end, his brow furrowed.

All of a sudden:

"Am I stupid! You must learn stenography, by jove!… Eh! … eh! … "

A jovial expression appeared on his face:

"And I forgot about the phonograph … the perfect confidante! It will allow us to turn it slower for listening than for recording … That's it then: you will stay with me during your stay in Amsterdam!"

The joy of a satisfactory vocation, of never having to spend vain and sterile days! Before the intelligent person of the doctor, in this scientific milieu, I felt a delicious well-being; the melancholy of my soul's solitude, the regret for my lost faculties, the long misery of a pariah that had crushed me for so many years, all disappeared, evaporated in the sentiment of a new life, a real life, a destiny saved!

VIII

The next morning the doctor made all the necessary arrangements. He wrote to my parents; he arranged a stenography teacher for me and procured some phonographs. Since he was extremely rich, and science was everything to him, there was no experiment he wasn't ready to try, and my vision, my hearing, my musculature, the colour of my skin were subjected to scrupulous investigations, the results of which made him more and more enthusiastic, crying:

"What wonders!"

I realised with marvel, after the first few days, how important it was that things were carried out methodically, from the simple to the complex, from the simple abnormality to the marvellous abnormality. I myself also had recourse to a little skill of mine, of which I made no secret with the doctor: that is, only to reveal my faculties bit by bit.

It was the rapidity of my perception and my movements that occupied him first of all. He hypothesised that the subtlety of my hearing corresponded with the speed of my speech. Graduated experiments on more and more fugitive sounds, which I was able to repeat back with ease, the sound of ten or fifteen people speaking at the same time, each of which I was able to understand perfectly well, proved the point clearly enough. The speed of my vision was no less proved by experiment; in comparative studies of my ability to decompose into separate images the gallop of a horse or the flight of an insect, and the same task carried out with instantaneous photographic apparati, demonstrated the superiority of my eye. As to my perception of ordinary things, the simultaneous movement of a group of people, of children playing, pebbles thrown in the air or little balls thrown in an alley to be counted as they flew – it amazed the family and friends of the doctor.

My walks in the large garden, my bounds of twenty metres at a time, the instantaneity with which I seized objects or replaced them were even more admired, not by the doctor, but by those around him. And it was a totally new pleasure, for the children and the wife of my host, on a walk in the country, to see me run ahead of a rider at a gallop or to follow the flight of swallows: there was no thoroughbred that I could not outrun by two-thirds, whatever the running, no bird that I could not easily outdo.

As for the doctor, more and more satisfied with the results of his experiments, he defined me thus: “A human being endowed, in all his movements, with a speed incomparably superior, not only to other humans, but to that of all known animals. This speed, found in every particular of his organism just as in the whole, makes him a being so distinct from the rest of creation that he merits a new category for himself alone in the animal hierarchy. As to the most curious disposition of his eye, as for the violet tint of his skin, we must consider them as simple indices of this special state."

Verification made of my muscular system, he found nothing remarkable, except for an excessive thinness. Neither did my ears seem to show any peculiar characteristics; nor, for that matter did my epidermis, except of course for its unusual colour. As for hair, of a rich dark colour, a violet-black, it was fine like a spider's web, and the doctor made a meticulous examination of it:

"We shall have to dissect you!" he sometimes said laughingly to me.

Time passed most pleasantly. I had picked up stenography very quickly, thanks to the intensity of my desire to do so, and the natural aptitude which I displayed for this method of rapid transcription, to which I actually introduced further new abbreviations. I began by taking notes, which the stenographer transcribed; and for the rest, we had phonographs, made to a design specially formulated by the doctor, and which we found perfectly suited to rendering my speech, at a slower speed.

The confidence of my host, over time, became unreserved. In the first weeks, he had not been able to avoid the suspicion – quite natural, of course – that the peculiarity of my faculties was not unaccompanied by some form of insanity, some cerebral derangement. Once disabused of this fear, our relationship became wholly cordial, and, I believe, equally captivating for both parties. We made an analytical examination of my perception of objects through a great number of different substances said to be opaque, and of the darkish coloration which water, glass and quartz had for me when a certain thickness. You will remember that I saw very well through wood, the leaves of trees, clouds and many other substances, but that I could distinguished but poorly the bottom of a pool of water half a metre deep, and that glass, although it might be transparent to me, was less so than for the common man, and was of a dark colour. A large piece of glass appeared almost black to me. The doctor was able to convince himself at leisure of all of these peculiarities – and was struck above all by observing how I was able to make out the stars on cloudy nights.

It was only at this time that I began to tell him how colour also seemed different to me. Experiments showed beyond doubt that red, orange, yellow, green, blue and indigo were as completely invisible to me as infra-red and ultra-violet to the normal eye. On the other hand, I was able to demonstrate that I could perceive violet, and, beyond violet, a range of graduated shades, a colour spectrum at least twice the range of that which extends from red to violet.[34]

This astonished the doctor more than all the rest. His study of it was lengthy, minute, and, meanwhile, conducted with infinite art. It became, in the hands of this able experimenter, the source of some very subtle discoveries in the order of the sciences, providing the key to phenomena as far removed as magnetism, affinity, inductive power, and guiding them towards new notions of physiology. To know that a certain metal contained a series of unknown gradations, which varied under pressure, temperature, electrical charge, that the finest gases had distinct colours, even when very thin; to learn of the infinite richness of tones of objects that appear more or less black, but which display a gamut of tones more magnificent in ultra-violet than all the known colours; to know lastly how an electrical circuit, the bark of a tree, the skin of a man, vary in unknown nuances during a day, an hour, a minute, – it is easy to imagine all the many lines of research an ingenious scientist might initiate on the basis of such notions.

---

[34] Quartz gave me a spectrum of around eight colours: extreme violet and seven colours beyond it within ultra-violet. But there remained about another eight colours which quartz did not separate further but which other substances separated more or less.

With his study, whatever it might be, the doctor was plunged into the delight of scientific novelty, set against which the products of the imagination are cold like ashes from the fire. He never ceased exclaiming to me:

“It’s clear! Your extra-perception of light is, essentially, just an effect of the great speed which your organism has developed!”

We worked patiently for a whole year without my making any mention of the Moedigen – I absolutely wanted to convince my host, to give him innumerable proofs of my visual faculties before venturing to bestowing on him the supreme confidence of this disclosure. Finally, the moment came when I felt I could reveal all.

IX

It was one morning, during a lovely autumn full of clouds, which had rolled along for a week in the dome of the sky, without any rain having fallen. Van den Heuvel and myself were walking in the garden. The doctor was silent and thoughtful, completely absorbed by speculations of which I was the principal object. Finally, he began to speak:

“It’s a lovely dream to be able to see through the clouds … to penetrate right to the ether, whereas we … blind as we are … ”

“If only I saw just the sky!” I replied.

“Ah! Yes, the whole world is so different for you … ”

“Even more different than I’ve told you so far!”

“How?” he cried, with avid curiosity, “have you hidden something from me?”

“The most important thing of all!”

He stood before me, staring at me fixedly, with a look of veritable anguish mixed with who knows what mystical intuition.

“Yes, the most important thing!”

We had arrived outside the house; I called for a phonograph. The instrument they brought me was of a scale perfected for my friend, able to record a long discourse; the domestic placed it on the stone table where the doctor and his family took their coffee on sunny summer days. The apparatus, a miracle of clockwork, lent itself admirably to discussions. Thus we pursued our conversation almost like a normal conversation:

"Yes, I hid the main thing from you, wanting to make sure first that I had your full trust. And even now, after all the discoveries my organism has allowed you to make, I still think it will be hard for you to believe me, at least at first."

I stopped to repeat the phrase using the machine: I saw the doctor become pale, the pallor of great scientists observing a new disposition of matter. His hands trembled.

"I will believe you!" he said with a certain solemnity.

"Even if I tell you that our creation, I mean our animal and vegetable world, is not the only life on earth … that there is another, just as vast, just as multiform … invisible to your eyes?"

He suspected some sort of occultism and couldn't stop himself from saying:

"The world of the afterlife … souls, the ghosts of departed spirits?"

"No, no, nothing like that. A world of living beings condemned like us to a brief life, to organic needs, to birth, to growth, to struggle … a world as precarious and ephemeral as our own, a world subject to laws just as fixed as ours, if not identical, a world that is also a prisoner of the earth, just as helpless before its contingencies … but nevertheless totally different to ours, without any influence on us, as we are without influence on it, – except for changes which it can effect upon our common ground, the earth, or by parallel modifications that we can make to this same earth."

I no longer knew whether Van den Heuvel believed me, but had no doubt he was in the throes of intense emotion:

"Are they fluid, then?" he asked.

"This is something I can't answer, because their properties are too contradictory to the idea which we have of matter. The earth is resistant to them as to us, the same for most minerals, although they can enter a little into a humus. They are totally impermeable, solid, in relation to each other. But they pass through, if with some difficulty, plants, animals, organic tissues; and ourselves, they pass through us in the same way. If one of them could perceive us, we would appear to them perhaps as fluid in relation to them, as they appear so in relation to us; but it would probably be unable to conclude anything, it would be so struck by parallel contradictions … Their form has the strange quality that it has no thickness at all. Their size varies to infinity. I have known one reach one hundred metres in length, other common ones as small as our smallest insects. Their nutrition is taken, for some of them, from the earth and from meteors; with others, from meteors and from other individuals of their kingdom, without this ever being cause for murder as it is with us, since it suffices that the strongest takes some energy and that this energy can be tapped without exhausting the sources of life."

The doctor said brusquely:

"Have you seen them since childhood?"

I suppose that he suspected some more or less recent disorder in my organism:

"Since I was a child!" I answered energetically … "I can give you all the details you want."

"Do you see them now?"

"I see them … the garden contains a great many… "

"Where?"

"On the path, on the lawns, on the walls, in the air … because, you see, there are terrestrial and aerial varieties … and also aquatic ones, but those ones rarely leave the surface of the water."

"Are there many of them everywhere?"

"Yes, but less in towns than in the fields, less in houses than in the streets. Those which like to be indoors tend to be smaller, doubtless because of the difficulty of moving about, although wooden doors are no obstacle to them."

"And iron … glass … brick…"

"They are impermeable to them."

"Can you describe one to me … one of the larger ones?"

"I can see one near to that tree. Its form is extremely elongated, quite irregular. It is convex on the right, concave to the left, with bulges and notches: one might imagine it as the projection of a gigantic, squat larva. But its structure is not typical of the Kingdom, because structure varies a great deal from one species (if you can use the word) to another. Its infinite thinness is, on the other hand, something common to all of them: they are never more than a tenth of a millimetre, whereas they are five feet long and forty centimetres at the widest point. What defines them most of all, and their entire Kingdom, are the lines which traverse them, in every direction, finishing in webs which get finer between two systems of lines. Each system of lines has a centre, a sort of slightly raised patch beneath the mass of the body, or sometimes on the contrary, sunken. These centres have no fixed form, sometimes almost circular, or elliptical, sometimes circumscribed or spiraloid, occasionally divided by many loops. They are astonishingly mobile, and their size varies from hour to hour. Their outline palpitates strongly, with a sort of transversal undulation. Generally, the lines which lead out from it are thick, although they can also be quite fine; they diverge, ending up in an infinity of delicate traces which gradually disappear. Some lines, meanwhile, far paler than others, don't belong to any centre; they remain isolated in the system and grow without changing in colour: these lines are able to move around the body, and to vary their curves, whilst the centres and the lines radiating from them remain stable in their respective places … As to the colours of my Moedig, I can't hope to describe them: there is nothing perceptible to the register of your eye, none of them have a name for you. They are extremely bright in the webs, less so in the centres, very faint in the independent lines which, however, do have a sheen, a metallic ultra-violet sheen, if I could describe it like that … I have collected various observations on the way of life, the nutrition, and the autonomy of the Moedigen, but I don't want to give them to you now."

I became silent; the doctor replayed several times the words inscribed on our impeccable intermediary, and then remained a long time in silence himself. I had never seen him in such a state before: his face was rigid, frozen, his eyes glassy, cataleptic; sweat ran down his temples and dampened his hair. He tried to speak but could not. Trembling, he made a round of the garden, and, when he reappeared, his look and his mouth expressed a violent, fervent, religious passion: one might have taken him for a disciple of some new faith rather than a serene researcher of phenomena.

Finally he murmured:

“You’ve got me beat! Everything you say seems hopelessly lucid, and have I really the right to doubt you, after all the marvels you have revealed to me?”

“Doubt,” I said to him warmly, “Doubt as strongly as you can … Your experiments will only be more fertile for it!”

“Ah!,” he replied in a dreamy voice, “it is a veritable miracle, and so magnificently superior to the vain miracles of legend and fable! … My poor human intelligence is so tiny compared to such knowledge! ... but my enthusiasm is infinite. However, something in me still doubts …”

“Then let us begin work on dissipating your uncertainties: our efforts will be repayed a hundredfold!”

X

We worked. It took several weeks for the doctor to fully dispose of his doubts. Ingenious experiments, irrefutable correspondences between each of my affirmations, two or three lucky discoveries about the influence of the Moedigen on atmospheric phenomena, left no remaining place for equivocation. The addition of the eldest son of Van den Heuvel, a young man full of the greatest scientific aptitude, increased yet more the fecundity of our work and the certitude of our findings.

Thanks to the methodical spirit of my companions, thanks to their power of investigation and classification – faculties which I was assimilating more and more – that which, in my understanding of the Moedigen, was uncoordinated and confused was transformed in no time. Discoveries multiplied, rigorous experiments gave firm results, from evidence which, in ancient times and even in recent centuries, might have suggested at most some fanciful speculations.

It is now five years that we have been pursuing our research: they are far, very far, from finished. The first report of our work will not appear for some time yet. We are, however, determined as a strict rule not to submit to haste: our discoveries are of too important an order to be reported but in the greatest of detail, with the greatest of patience, and with the most minute precision. We have no other researcher to compete with, no brief to follow nor any ambition to satisfy. We exist at such heights that vanity and pride are no longer an issue. How can we reconcile the delicious joys of our work with the miserable enticement of human fame? In any case, isn't the random chance of my constitution the source of the whole affair? In which case, how base it would be of us to glorify ourselves because of it!

We live passionately, always on the verge of marvellous things; but also we live in an immutable serenity.

*

Something has happened to me which may add to the interest of my life, and which, in my rest, has brought me infinite joy. You well know how ugly I am, how strange, fit to scare away any young lady. However I have found a companion who has been able to accept my affections to the point of our being happy together.

She is a young girl, a hysteric, with a nervous illness, who we encountered one day in a hospice in Amsterdam. You would say she had a miserable look about her, as pale as plaster, hollow-cheeked, wild-eyed. But to me, her aspect seemed agreeable and her company most charming. My presence, far from astonishing her, as it did all the others, seemed from the first to please and to comfort her. I was touched by her, I wanted to see her again.

It did not take long to notice that I had a beneficial effect upon her health and her well-being. On closer examination, it appeared that I affected her magnetically: my approach, and above all the touch of my hands, communicated a gaiety to her, a serenity, a truly restorative spiritual equilibrium. In return, I found great joy being with her. Her face appeared so pretty to me; her paleness and her thin body were the fondest delicacy for me; her eyes, capable of seeing the glow of lovers, like those of many hyperesthetics, hadn't for me in the slightest that character of wildness of which she was accused.

In a word, I felt a great affection towards her, which she reciprocated with passion. So that I took the decision to marry her, and arrived easily at this goal, thanks to the goodwill of my friends.

The union was a happy one. My wife's health returned to her, although she remains extremely sensitive and frail; I tasted the joy of being, in principle at least, equal to other men. But my destiny has been even more enviable since six months ago: a child was born to us, and in this child are united all the characteristics of my constitution. Colour, vision, hearing, extreme rapidity of movement, nutrition – he promises to be an exact replication of my organism.

The doctor watches him grow up with delight: a delicious hope has come to us – that the study of the life of the Moedigen, of that Kingdom parallel to our own, that study which demands such time and such patience, shall not end when I am no more. My son will continue it, no doubt, in his turn. And why should he not find collaborators of genius, capable of taking it to new heights? Why should he also, in turn, not father new witnesses of the invisible world?

And may I not myself expect more children, may I not hope that my dear wife will give birth to new offspring of my flesh, just like their father? … In thinking of it, my heart trembles, an infinite beatitude overcomes me, and I feel blessed amongst men.

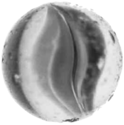
Speculative Realism

A One-Day Workshop
1–7pm, Friday 27 April 2007
Lecture Hall, Ben Pimlott Building
Goldsmiths, University of London
New Cross, London SE14 6NW

Participants: Ray Brassier (Middlesex), Iain Hamilton Grant (UWE), Graham Harman (American University in Cairo), Quentin Meillassoux (Ecole Normale Supérieure)



Contemporary 'continental' philosophy often prides itself on having overcome the age-old metaphysical battles between realism and idealism. Subject-object dualism, whose repudiation has turned into a conditioned reflex of contemporary theory, has supposedly been destroyed by the critique of representation and supplanted by various ways of thinking the fundamental correlation between thought and world.

But perhaps this anti-representational (or 'correlationist') consensus – which exceeds philosophy proper and thrives in many domains of the humanities and the social sciences – hides a deeper and more insidious idealism. Is realism really so 'naïve'? And is the widespread dismissal of representation and objectivity the radical, critical stance it so often claims to be?

This workshop will bring together four philosophers whose work, although shaped by different concerns, questions some of the basic tenets of a 'continental' orthodoxy while eschewing the reactionary prejudices of common-sense. Speculative realism is not a doctrine but the umbrella term for a variety of research programmes committed to upholding the autonomy of reality, whether in the name of transcendental physicalism, object-oriented philosophy, or abstract materialism, against the depredations of anthropocentrism.

Schedule
Chair: Alberto Toscano (Sociology, Goldsmiths)
1-1.15 Welcome
1.15-2.30 Ray Brassier
2.30-3.45 Iain Hamilton Grant
3.45-4.15 Break
4.15-5.30 Graham Harman
5.30-7.00 Quentin Meillassoux
7.00-8.00 Drinks

for further information, and advance excerpts of speakers' work see http://www.goldsmiths.ac.uk/csisp/
THIS EVENT IS FREE, BUT PLEASE REGISTER BEFOREHAND BY EMAILING a.toscano@gold.ac.uk

Speculative Realism

Ray Brassier, Iain Hamilton Grant,
Graham Harman, Quentin Meillassoux

'Speculative Realism: A One-Day Workshop' took place on 27 April 2007 at Goldsmiths, University of London, under the auspices of the Centre for the Study of Invention and Social Process, co-sponsored by **COLLAPSE**. *Rather than announcing the advent of a new theoretical 'doctrine' or 'school', the event conjoined four ambitious philosophical projects – all of which boldly problematise the subjectivistic and anthropocentric foundations of much of 'continental philosophy' while differing significantly in their respective strategies for superseding them. It is precisely this uniqueness of each participant that allowed a fruitful discussion to emerge. Alongside the articulation of various challenges to certain idealistic premises, a determination of the obstacles that any contemporary realism must surmount was equally in effect. Accordingly, some of the key issues under scrutiny included the status of science and epistemology in contemporary philosophy, the ontological constitution of thought, and the nature of subject-independent objects.*

COLLAPSE III, ed. R. Mackay (Falmouth: Urbanomic, November 2007)
ISBN 978-0-9553087-2-0

However, as workshop moderator and co-organiser Alberto Toscano indicated, a common feature of the work presented was the implication that from a genuine interrogation of the continental tradition necessarily ensues a repudiation of the orthodoxies symptomatic of that tradition's conceptual exhaustion (the most visible of which being the seemingly endless deluge of insipid secondary literature and the 'X-ian' identity of its authors), thus rendering the task of doing philosophy 'in one's own name' essential once again. 'Speculative Realism', then, forces contemporary philosophy to make a decision, but it is not so much one concerning idealism or realism. Rather, at stake here is the possibility of a future for audacious and original philosophical thought as a discourse on the nature of reality – or, as one might otherwise call it: philosophy itself.

PRESENTATION BY RAY BRASSIER

Rather than reading a paper, I'm just going to make some general remarks about what I take to be the really significant points of convergence and divergence between Iain, Graham, Quentin, and myself. The fundamental thing we seem to share is obviously a willingness to re-interrogate or to open up a whole set of philosophical problems that were taken to have been definitively settled by Kant, certainly, at least, by those working within the continental tradition. This is why, as I'm sure everyone knows, the term 'realist' in continental philosophy is usually taken to be some kind of insult – only someone who really hasn't understood Kant could ever want to rehabilitate something like metaphysical realism, or any form of realism which does not depend upon some kind of transcendental guarantor, whether that guarantor is subjectively instantiated by pure apperception, or construed in terms of linguistic practices, or a communicational consensus, etc. Much of the mainstream of nineteenth and twentieth century post-Kantian philosophy is about simply redefining, generalising, specifying, these transcendental structures or conditions of cognitive legitimation. And in a way, it doesn't really matter whether you claim to have replaced the subject and the object with some form of communicational consensus or being-in-the-world or any variant of the latter on these issues: The transcendental function has been variously encoded in different versions of post-Kantian continental philosophy. But the thing that seems to be assumed within this tradition, the thing that actually Graham's work first brought out to me, is the notion that whatever structure there is in the world has to be transcendentally imposed or generated or guaranteed, which is to say that objectivity can only be a function of synthesis. And it's striking that in post-Kantian philosophy the difference between Kant and Hegel seems to be that where Kant will localise the synthesising function in something like pure apperception or wholly on the side of the subject, Hegel and the various forms of objective idealism will say that reality itself is self-synthesising, that there is a kind of principle of synthesis encoded in objective reality itself. So that, famously, in Hegel's objective idealism, the relational synthesis which Kant takes to be constitutive of objectivity is simply transplanted from its localisation in the subject and construed rather as the relation between subject and object, which Hegel recodes as the 'self-relating negativity' that yields the structure of reality. So the question is: If you refuse to say that synthesis – the synthesis which produces objective structure – is anchored in a subject, does this mean that you have to idealise the real by attributing to it this capacity for self-relation? A capacity for self-synthesis whereby a continuum of relation itself yields the type of discontinuity that gives rise to discrete objects? In other words, is there a principle of intelligibility encoded in physical reality?

This is absolutely the key issue, I think, in Iain's book on Schelling.[1] And according to Iain's reconstruction, Schelling proposes an alternative variant of objective idealism, one wherein structure and objectivity are intrinsic to nature, but the ideal structures that are intrinsic to or inherent in physical reality are no longer construed in terms of a dialectic of opposition and contradiction. In Iain's brilliant reconstruction of Schellingianism, what you get is something like a 'transcendental physics', a physics of the All, where ideas are differential dynamisms, attractors immanent to and inherent in material reality. So, nature is self-organising. And the ideal structure of nature produces the structure of thinking. But if cognition is a result, a product – if it's every bit as conditioned as any other natural phenomenon – the question then becomes whether there's any reason to suppose that thought can limn or grasp the ultimate structure of reality at any given moment, any specific historical juncture. Because the key thing, if you're committed to a transcendental realism, of which Iain provides a powerful reconstruction in his book, is that it is the structure of material reality that generates the structure of thinking. But this means that one must discount any appeal to intellectual intuition, which is to say, the idea that thinking can simply transcend its own material, neurobiological conditions of organisation and effectuation and grasp the noumenal structure of reality as it is in itself. The problem is this: If the structure of reality produces the structure of thinking, then the challenge is to avoid both transcendentalism and a kind of pragmatism which would say that evolutionary history simply guarantees the congruence between representation and reality as a function of adaptational necessity, so that only creatures that have a cognitive apparatus that is appropriate to their kind of biophysical environment will be able to survive. And this is a claim that fuels much of naturalised epistemology, but one that I think is metaphysically problematic, because there is no reason to suppose that evolutionary adaptation would favour exhaustively accurate beliefs about the world. There's no reason to suppose that evolution would infallibly provide human organisms with a cognitive apparatus that can accurately track the salient features or the deep structure of reality. So in other words, there seems to be a kind of incompatibility between any pragmatic, adaptationist rationale for cognitive functioning, and scientific realism, which says that the physical structures of reality, as articulated by the natural sciences, can't simply be explained in terms of their usefulness as viable survival strategies. And the force of Iain's book is to try to propose what he calls a 'transcendental naturalism' – which claims that you can explain the emergence of the structure of ideation from the ideal structure of physical reality, so that ideation would be capable of tracking the ideal dynamisms, the transcendental dynamisms, that underlie merely empirical or merely somatic reality.

---

[1] Iain Hamilton Grant, *Philosophies of Nature After Schelling* (London: Continuum, 2006).

An important distinction in Iain's book is between the Aristotelian-Kantian reduction of materiality to somatic or corporeal reality – the idea that to be material means to be some sort of body with a set of perceptible properties – and the transcendental materialism that Iain ascribes to Schelling, where the real material structures are the abstract differential dynamisms that generate and produce bodies, organisms, and spatio-temporal objects, but can never be reduced to them. But here's one consequence of this: if the structure of ideation is a function of the ideal structure of material self-organisation, then the process is ongoing – and Iain emphasises this – so it's simply not the case that biological history has reached some sort of apex in human consciousness. And if the process is still ongoing and will keep going, then not only is there more to know about the structure of *reality* than we currently know just now; there's also more to know about the structure of *ideation* than we currently know. And I think this presents a quandary for someone who's committed to a version of speculative realism: transcendental physicalism insists that there are real conditions of ideation but that these conditions have an ideal structure. The question then is: can the specific conceptual details of these ideal physical structures be satisfactorily identified using the currently available resources of conceptual ideation? What does this mean? It means using either the available registers of mathematical formalisation available to contemporary science; *or* – if we are thinking in terms of transcendental philosophy – a set of suitably generic conceptual categories. But then, can we be sure that any of the abstract conceptual categories in terms of which we propose to reconstruct these ideal structures

Ray Brassier

are applicable? Can we be sure that these self-organising features of material reality can be linguistically encoded and encapsulated? In other words, are the resources of natural language sufficient to successfully articulate the transcendental dynamisms that fuel material processes? Or do we need to discover more about the machinery and structure of ideation before we can confidently specify the physical structure of nature? So, as regards the characterisation of ideas as 'phase space attractors', the question is whether that could ever satisfactorily characterise the underlying dynamisms of physical nature. More importantly, with regard to the category of 'dynamism', which, as Iain shows, goes back to Plato and Aristotle: Is it enough simply to supplant a somatic or Aristotelian metaphysics, which equates material reality with constituted bodies, products, organisms, and objects with a metaphysics of dynamisms as the real, underlying motors of self-organisation, or ultimate generators of material structure?

So, I guess what I'm asking is: what is the status of dynamism in speculative physics? Is it truly adequate to physical infrastructures? Or might it not be contaminated by certain folk-physical prejudices? I agree with Iain about re-inscribing the machinery of ideation within the physical realm, and about the need for a transcendental naturalisation of epistemology, but wonder whether that re-inscription provides a warrant for what he calls 'speculative physics'. What is the relationship between the dynamic structure of the idea and the mathematical register deployed for its formalisation? So my question to Iain then is really about the status of epistemology within transcendental materialism: Although the advantages of the latter vis-à-vis the pragmatic variants of naturalised epistemology are fairly evident, I think there's an issue here about what articulates ideation and the mathematical resources of ideation that have been crucial in ridding us of this parochial Aristotelian model of physical reality. It was the mathematisation of nature that definitively ruined and shredded the medieval Book of the World. And the question is, can we rehabilitate a form of transcendental or speculative materialism or realism that would also explain the success of mathematical formalisation in supplanting the old, pre-Galilean models of physics and metaphysics?

One final point, concerning the nature of dynamism, and this is a general point related to process philosophy:

If you privilege productivity, if these ideal generative dynamisms that structure and constitute material reality can be characterised in terms of the primacy of production over product, then the question is, how do we account for the interruptions of the process? How do we account for discontinuity in the continuum of production? And while I have no doubt that it's possible to do so, I think it's a significant problem for any process philosophy that wants to defend or prosecute a form of ontological monism based on something like 'pure productivity', 'pure becoming', 'duration', or whatever one chooses to call it. Because then it seems that you always have to introduce or posit some sort of conceptual contrary, some principle of deceleration, interruption, disintensification or whatever, in order to account for the upsurges of stability and continuity and consistency within this otherwise untrammelled flux of becoming and pure process. So even if one then goes on to reintegrate it into the former as a mere moment, one still has to explain why there is anything but pure process or why the processual flux is ever momentarily stabilized. It's striking that you see this in Bergson: the idea that you need something to explain what interrupts the process, what produces or introduces discontinuity into the flux of becoming.

And I think Graham's contribution lies precisely in this key area. The idea is that if you begin with some form of preliminary methodological dualism of production and product or, in its classic Bergsonian articulation, something like duration and space, then you need to explain what interrupts the continuum – how duration ever externalises itself or coagulates into something like a spatial fixity or stasis. And Graham gets around this problem by simply having a metaphysics of objects, which in a way removes the question of synthesis altogether. What's striking about Graham's account is that you don't need to explain how objects are synthesised, because you simply take objects as nested within one another. You have this kind of infinite nesting of objects within objects within objects … Every relation between objects itself unfolds within another object. So Graham turns the question around by showing how the problem consists in showing how discontinuous, autonomous objects can ever enter into relation with one another – his answer is that they do so on the inside of another object. In other words, every relation is itself another object. So what you have then is a kind of egalitarian objective univocity, a kind of ontology of pure objectivity: there are nothing but objects, objects nested within one another, and the really significant metaphysical challenge is explaining their interaction.

But I have two questions vis-à-vis Graham's project: First, Graham explains the interaction between objects in terms of their sensual properties, *i.e.*, no object ever exhausts the ultimate reality of another object. It engages or interacts with it on the basis of a set of sensual or perceptible properties, and it is these that provide the basis for the reciprocal interaction between objects. And my question is: what is the criterion for distinguishing sensible from non-sensible properties for any given object? Is it possible to provide such a criterion without giving it some sort of epistemological slant or formulation? In other words, in order to interact with one another, it seems that objects need to 'know' something about one another. The fire must 'know' that the cotton is not rock; the rock must 'know' that the ice is not water. Whatever kind of interaction objects have, the fact that their interface is possible on the basis of this recognition of something like sensual properties, which are capable of locking together and causing the interaction – well, I think the question is whether it is possible to explain how objects discriminate between the sensual or perceptible and the imperceptible properties of any other object. And this ties into a second question, which is about the status of the distinction between real and imaginary objects for Graham, because, for Graham, it makes no sense to ask whether something is real: everything is real, everything is objective, so nothing is more real than anything else. He provides us with an absolutely egalitarian, flat ontology of objects. But the danger then is – and Graham and I have spoken about this before – that this would simply license too much or result in too liberal a construal of objectivity. For instance, what would be the distinction between a hobbit and a quark here? This is a very serious metaphysical question! And Graham maintains that the properties of the hobbit or any other kind of fictitious, contrived, artificially generated example would be purely imaginary, and of course one can contrive and generate imaginary qualities for imaginary objects. But how do we make the distinction, given that we know that imaginary objects or fictitious entities such as the Virgin Mary or Yahweh or phlogiston seem perfectly capable of producing real effects – it's perfectly possible for these things to generate real effects in so far as people believe in them and do things in the world on the basis of their belief in them. If we say that this is a misdescription, and that there's actually a real object underlying the imaginary object, and it is this real object that causes things to happen, then the question is: on what basis do we make this distinction if not by invoking some form of epistemological criterion that distinguishes between real and imaginary properties or objects?

In other words, my question to Graham is: Is it possible to prosecute an ontology of objects without explaining *how it is that we are able to do so*; *i.e.* how we seem to have to *know* something about objects? This is not to reintroduce the Kantian primacy of the subject, but just to say that even objects seem to have to know certain things about one another in order to interact, just as we seem to have to know something simply in order to be able to describe and identify objects. And Graham is clear that the epistemological relation, which Kantianism took to be absolutely primary and fundamental – *i.e.*, the subject-object relationship – is merely a relation between objects just like any other. It has no kind of epistemological or transcendental primacy, so that explaining how we're able to know the laws of mechanics is an interesting question, but it's not really fundamentally different in kind from explaining how fire is able to burn cotton, or how a marble is able to interact with a table. But I think I want to problematise this issue further – my conviction is that it's not so clear, and that philosophy should do more than simply generate a formal metaphysics of objects; my conviction is that describing or reconstructing the structure of interaction between objects does not exhaust the task of philosophy.

And finally, I'm just going to say a few things about Quentin and how I situate myself vis-à-vis his work. My key reservation concerns the status of intellectual intuition.

Quentin defends the claim that mathematical ideation, mathematical intellection, has a grasp of things-in-themselves. It grasps the intelligible structure of reality. He has an extremely interesting hypothesis about why it's precisely the meaninglessness or the insignificance of mathematical inscription that allows you to grasp what he calls the 'absolute contingency' of reality. But he explicitly wants to rehabilitate the Cartesian project, where mathematical ideation accurately describes the objective structure of reality as it is in itself, against the Kantian one, which would limit the scope of scientific cognition to the phenomenal realm. My question is very simple: Is it possible to abstract ideation from the physical reality which it grasps or apprehends, given what we know since Darwin, *i.e.*, that the capacity for mathematical ideation which underwrites the objectivity of scientific cognition is the result of a long process of evolutionary development? And the question here again is: Can one concede that ideation, even the most sophisticated form of abstract conceptual ideation as it's deployed in mathematical science, simply supervenes on a set of fundamental neurobiological processes? Can one grant this without reducing cognition and ideation to pragmatic expediency – *i.e.*, the claim that we represent the world in the way we do because evolution has guaranteed this congruence between mind and world (a claim which I think provides an extremely feeble warrant for scientific realism)? In other words, can one reject pragmatism, and naturalist pragmatism in particular, without ascribing some kind of mysterious transcendence to thinking; without saying that thinking, and specifically scientific cognition, is this mysterious kind of capacity that human beings have either stumbled upon or had bestowed upon them by some mysterious sort of process, and which it's impossible to try to understand in more rudimentary terms? And I think that arguably *the* most significant philosophical development of the twentieth century is the emergence of a science of cognition; that is, the idea that the process of cognition can be re-integrated into the realm of objective phenomena studied by the empirical sciences. In other words, there's a circle here, and a circle which, I think, is too quickly disqualified as vicious by transcendental philosophy. Husserl tried to disqualify psychologism on the grounds that if you reduce ideation to a set of psychological processes, then you remove the dimension of necessity, of logico-mathematical validity, which is the guarantor for the cognitive authority of the natural sciences. In other words, you reduce scientific discourse to a discourse like any other discourse, simply a way of speaking, and you basically turn into Richard Rorty.

So, as I see it, the key challenge for speculative realism is: Can one be a realist about the sorts of entities and processes postulated by the sciences without having to shore up that commitment to realism with some sort of pragmatism on the one hand, or transcendentalism on the other? Can one be a naturalist without turning into Richard Rorty, and can one maintain that what science says is true without becoming a Husserlian or something of that ilk? And I think this is a really interesting question; I think this is where some kind of communication is needed between the speculative audacity which is a characteristic of so-called 'continental philosophy' and the really admirable level of engagement with the empirical sciences which is a feature of the most interesting work being done specifically in the kind of Anglo-American philosophy of mind that engages directly with, or that sees its project as continuous with, cognitive science. So, can one be a transcendental realist without idealising ideation, but without reducing it to a set of pragmatic functions either?

*

Iain Hamilton Grant: This is fascinating, Ray, not least because I've never heard anyone talk about my work before! But several things you mentioned brought to mind certain features which I think are perhaps necessary to any speculative project. One of them is a certain commitment to a variety of realism, and the question is, which realism? And my question is: Is it possible that there is a realism which is in some sense eliminativist? Because if so, then there are all sorts of ontological problems with that. If not, then, if nothing can be eliminated, then we have a situation where it no longer makes sense to ask, 'What is the difference between a hobbit and a quark?', or for that matter, between Rorty and Husserl! Actually, is there one? Or rather what are the differences? There are several differences between these entities, but to use a difference as a disqualification for their being 'real' or not is simply to beg the question about realism, fundamentally. And for that reason, it seems to me that a non-eliminative realism is committed to becoming a form of idealism, in which case we merely extend realism to the Ideas: In which case we no longer have the problem of the separativity, the subtraction, of ideation from nature, which you were suggesting might be a problem; nor do we have the reducibility to a simple state of affairs whose mere existence guarantees an equilibrium reached between the forces of nature and this highly evolved product or what have you – what you've described as 'pragmatism'. So really my question to you is – and this is also in the light of what reading I've done of your book,[2] really – what are the grounds on which it would become possible for any realist to say, '*x* or class *x* or category *x* cannot and does not enjoy being'?

RB: Well, the traditional way, although it may be completely implausible, is to say that to be real is to make a difference. Anything that makes a difference is real. And of course, then you have to say, 'Well, it has to be a *real* difference, so what do you mean by *real* difference?' And one traditional response to this is that anything that has effects, anything that produces effects, must be real, no matter how else it might be qualified. And this is the key question for Graham, who refuses any distinction between the real and the imaginary, so that it doesn't make sense to ask if anything is more real than anything else. I can see why, because it seems that the difficulties attendant upon trying to articulate a difference between what is real and what isn't just seem insuperable. But it seems to me that if you're willing to grant that we know more about the world than we used to – which I know some people are not willing to grant, but which I'm kind of desperately wedded to – then it seems that you want to say that what happens when we discover something real about the world is that we discover the real causal mechanism, we discover what is *actually* making the difference – so it's not the Virgin Mary who's making the difference, it's a complicated set of processes for which the Virgin Mary is some sort of figurative shorthand. In other words, I'm not simply saying there is no such thing as the Virgin Mary, because clearly there is, in the same sense simply in which there are such things as hobbits or unicorns: the sense in which all these things have made a difference to *our* world, at least. But the claim would be that this is a kind of a folk-language, a kind of linguistic shorthand to describe something else, something that is inapparent, and whose proper description would invoke complex configurations of psychological, as well as socio-historical, processes. In other words, this stuff happens, everyone knows it: why is it that people's apparently false beliefs can have real consequences in the world? The answer would be because we can account for how things can happen even when we ourselves as agents of that happening are deluded about the causally salient factors. There is a way of describing what the salient mechanisms are that produce what's happening. And I think the question of scientific realism is: What are the salient mechanisms that make a difference in the world, that produce difference? In the history of science, phlogiston, calorific fluid, etc. – these things were thought to be viable explanatory categories, and when we dispensed with them, when we said, 'No, that's not an adequate explanation for heat, etc.', we realized we were misconstruing or misdescribing the relevant factors or mechanisms. My conviction – and I think it's a necessary conviction if you want to be a transcendental realist – my conviction would be that we can always misdescribe the structure of reality, but that doesn't mean that there isn't a kind of underlying, deep structure, even if there's always going to be something unsatisfactory or superficial about the mechanisms that we describe. For instance, when Newtonian physics was supplanted by Einsteinian physics – did Einstein 'falsify' Newton? Well, not really, he just showed that his physics had only a limited domain of applicability. And it seems to me that that's the dynamic, the cognitive dynamic that underlies science. It's not that we discover that what we knew was false, but rather that it was limited. This is what it means to find out more about the world, that there's much more going on, and that it turns out to be more complicated, and that we need to forge new resources in order to be able to adequately describe or identify these complex processes. So, in a way, the distinction then wouldn't be between what's real and what isn't real, but between degrees, I suppose – possibly between degrees of adequation. And I think it's possible to describe what adequation would be, what it means for thought to be adequate to its object, without resorting to a Kantian framework. But I'm still groping at this. I really haven't got anything worked out, so these are just kind of intuitions.

---

[2] Ray Brassier, *Nihil Unbound: Enlightenment and Extinction* (Basingstoke: Palgrave Macmillan, 2007).

GRAHAM HARMAN: Ray also mentioned a few things about my work that I can respond to. First I want to say, though, in your response to Iain you mentioned defining the real as that which has effects, and I would encourage you to stay away from that definition, because then it seems like you're defining the real by something outside the real. So it's not the real in its own right, but something outside of it – potential or something. We can argue about this, but this is why I shy away from that definition, just as I shy away from the definition ‘reality means resistance’, which you see in Heidegger and Max Scheler and others. That might be a way we measure reality, but that can’t be reality in itself, because *something* is resisting. The resistance itself is at best a way of *knowing* the reality.

The last thing you asked about my work was whether I think that this theory of relations between objects exhausts philosophy, and at this point I’m not in a position to say yes or no – but that’s definitely my project, that’s what I’m trying to say. And just in the last week in London I’ve decided what I’m going to do for the second half of this next book, which is go through every one of the metaphysical problems that Kant throws out and try to rehabilitate every one of them – such as, ‘is there a smallest possible unit of substance, or does the division go on forever?’, ‘is there freedom or no freedom?’ It would be fun to try to rehabilitate all these problems in terms of objects and the relations between them. I was struggling with how to organise that metaphysical part of the manuscript, but I think this is the way to do it, since Kant is the one who destroyed all these problems, according to everyone. Why not just go right in his face and try to bring them all back? Who knows if it will work or not, but it should be fun.

The hobbit and the quark, I think, was the second point, and that’s actually easier to deal with than the first. I’m a Latourian on this point. For Latour, every kind of object is real, and you simply judge an actor by how many allies it has, and what sorts of … – I almost said ‘effects’, I’m contradicting myself – how well it resists tests of strength that are made against it. Clearly a hobbit has to be a real object in some sense, because I can ask ‘What is a hobbit?’, ‘What does a hobbit do?', 'How does it behave?', and this will never be completely reducible to all the things that Tolkien says in all of his novels, because you can imagine new scenarios. You can ask, 'Could a hobbit fit in a Lovecraft story?', 'Could a hobbit fit in a Proust novel?' I would say no. Now why is that? It's never been tried, so why is it that when I mention these possibilities we immediately reject them? It's because you have a sense of what the hobbit is beyond all of the things that have been said about hobbits in films and novels that we already know. So I'd say a hobbit is real. Okay, of course you don't want to say a hobbit is as real as a quark – why not? Or to take an even sharper example, you don't want to say that five hundred imaginary crowns are the same as five hundred real crowns. And the way I would deal with that problem is as follows: The traditional pre-Kantian solution was to say there isn't really anything different in the two. God creates the five hundred real crowns, being becomes a real predicate in the real ones that wasn't there in the imaginary ones. And then Kant says it's not a real predicate, it has to do with our position, namely their relation to us. But why not say that the five hundred real crowns and the five hundred imaginary crowns do not have the same qualities in the first place? They differ in essence, not just existence. That's my solution, and it's not fully worked out yet. The shiny gold lustre of the real coins is not the same as that of the imaginary coins, because somehow qualities are borrowed from the parts of a thing, I would say, and the five hundred real crowns have real parts, the five hundred imaginary crowns do not. So that's the direction I would go in, to answer that: to say that everything is real, and that the qualities of things are not universals. The qualities of things come from individual parts. And then you have to explain what universals are, which is another problem I haven't even touched yet – how do you explain what 'red' means?

The first question you asked was the hardest. Objects interact on the basis of essential properties. In order to interact, objects need to know something of one another. I'm not sure if this answer will satisfy you, but what I say is that objects do not interact with each other directly, but simply somehow allude to each other, and what they're coming in contact with are qualities of each other, that somehow allude to the things. And I think you see this in metaphor, and this is the example I used in *Guerrilla Metaphysics*[3]: The example Max Black uses was 'man is a wolf', which is a different metaphor from 'wolf is a man', it has a completely different effect. When you've got 'man is a wolf' in Black's example you have some sort of elusive human thing there that's being orbited by wolf qualities that are transformed in a human direction. But somehow those qualities allow you access to the human underneath that wolf-man thing, whatever it is. So, things do interact but they interact only on the interior of another object where one of them is merely sensible, or an intentional, object, and you're trying to point at a real object in that way.

I don't want to hog the time here, but I was going to answer Iain's rhetorical question about whether there's a difference between Husserl and Rorty. I think there is a difference, and the difference is that the key to Husserl is the intentional objects. Husserl *is* speaking of the phenomenal realm, but he's also speaking of a phenomenal realm broken up into objects that are never fully exemplified by our specific perceptions of them – I think that's his great discovery. These are different from real objects that withdraw and hide as in Heidegger and in various realists. In Husserl what you have are objects that are already there yet somehow covered over with too much detail, so you have to eidetically vary them and circle the thing from many different directions and finally, asymptotically perhaps, get at what the thing is by looking at it from all the different possible angles. And you certainly don't see that in any of the empiricists. Objects are merely arbitrary bundles imposed by us on sense data, for empiricists. Whereas I think the object is really there, organising the qualities, and Merleau-Ponty actually does a nice job on this. I'm not the greatest fan of Merleau-Ponty, but he does a nice job arguing that the black of a pen is not the same as the black of a coat – there's a connotation to the blackness that is different in each case, because the quality is somehow impregnated with the object to which it belongs. So … I will let our visitor from Paris take the reins now.

---

[3] Graham Harman, *Guerrilla Metaphysics: Phenomenology and the Carpentry of Things* (Chicago: Open Court, 2005).

Quentin Meillassoux: Thank you, Graham. I would say the following about formalisation, mathematics, in relation to the world: I don't want to demonstrate that there is a necessary relation between mathematics and reality. My problem is a problem of *possibility*. In *After Finitude*,[4] the problem that I encounter is that of explaining the possibility of science, physics, being able to describe a world without humans. For a transcendental philosopher, for what I call ‘correlationism’, this makes no sense – it is an absurd question to ask, ‘What would the world be if there were no humans?’ ‘What would the world be like if we didn’t exist?’ – This is an absurd question, *the* absurd question, I think, for every Kantian or post-Kantian philosophy. But the problem is that sciences are supposed precisely to explain what the world is like even if there are no humans. What is the world before humanity? What could the world be after humanity? So, my problem is just a problem of possibility. What distinguishes scientific description is its mathematicity. So, the problem that I encounter is to explain how mathematics might possibly be able to describe this world. Of course this description may be deficient, it may be that there is far more in the world than mathematics is able to describe. But at least we must explain the possibility that the theory – a theory which may be refuted in the future – a physical theory, might be able to describe the world. That is the fact I want to explain. I don’t feel that contemporary theories are necessarily true – maybe they are false, but maybe they are true; this ‘maybe’ must be explained. So, it is really a modest position. I just want to explain the possibility of mathematical explanation. For I think this possibility is a condition of an explanation of science itself. By which I mean: how it is possible that mathematics could be able to describe the world, even a world without humans. This is the problem of science.

---

[4] Quentin Meillassoux, *Après la finitude: Essai sur la nécessité de la contingence* (Paris: Seuil, 2006), translated into English by Ray Brassier as *After Finitude: An Essay on the Necessity of Contingency* (Continuum: London, forthcoming 2008).

About Rorty and Husserl, I would say this. I think that every time a Rortian speaks and argues, he always has the following position. He always says that, ‘Your discourse is a contingent discourse, a discourse among other possible discourses'. And he will say that about mathematics. So, I will say he has this sort of primitive theme in his mind: Maybe there could be some non-human organism, some extra-terrestrial, that would be able to have a radically different relation to the world – a different perception, different conceptual apparatus, etc. So all discourses are historically or maybe biologically contingent. So I would say that contingency is the ground of every relativist theory. What we have in common with every human or non-human discourse is that we think we are able to be Rortian – even an extra-terrestrial can be Rortian. And imagine an extra-terrestrial which was Rortian – what would he say? He would say the same as the terrestrial Rortian, he would say, 'Maybe all discourses are contingent, maybe there could be other possible discourses, *etc.*'. So contingency is a common property of all relativisms of all times, on all planets. That's why I made contingency the real ground, the universal and eternal ground, of every relativism in the universe – I'm sure of that. So, if there is a certain sure ground of every discourse, which would be accepted by every Rortian – human or non-human – I would say it would be contingency. So, my problem is very simple: are we able to derive, to deduce, from this eternal ground – which, according to me, is contingency – the capacity of mathematics to possibly be able to describe a world without humanity? I have the ground, I have the problem. Between them what I try to show is, if contingency is eternally true, maybe there are determinations of contingency itself. Maybe to be contingent, you must be *a* or *b* or *x*. Because you can't be just anything if you want to be contingent. My hypothesis is that to be contingent you must not be contradictory, because if you are contradictory you are everything and you can't change. So if I can derive, deduce – but I don't yet do this in *After Finitude* – if I could derive from contingency a condition which explains the possibility of mathematics describing a world without humanity, okay, bingo. I didn't do that in *After Finitude*. But I think it's possible. And in that case, you know, we would be sure to be immune from Rortian refutation, because Rortian refutation is always grounded on contingency; and on the other hand, we would have explained what must be explained to understand the capacity of sciences to possibly describe a world without us.

RB: Okay. It's a question of scientificity here: whether mathematical formalisation or mathematical science can and should be the privileged paradigm of scientificity. Because there's another issue here, which is that lots of what we know about the world before and after humans is not mathematical knowledge. Lots of biology and geology is not mathematically formalised. And yet surely we want to say that we know that dinosaurs existed, and that we know quite a lot about the morphology of brontosauruses. I mean, I know the question of dating is crucial here, but it's not just that we know that the accretion of the earth happened 4.5 billion years ago because we have a mathematical way of determining the date, but that we know much more. We know about the processes involved, which are geological, physical, chemical processes, just as we know an incredible amount about the pre-human world, about pre-human flora and fauna. And surely it's important to be able to defend the reality of the claim that brontosauruses had such and such a property. There's very little that is mathematical about what we know about brontosauruses. And my worry is that if you turn mathematisation into the criterion of scientificity, you accidentally or unwittingly compromise the authority of all sorts of non-mathematical knowledge, which surely we want to say is objective: geology, biology, etc. And this can be turned around, because lots of people will say – an idealist will say – certainly mathematics is the only reliable guarantor of objectivity, the irrefutable canon of objective validity, and they will use that to discount biology and all sorts of other things. And this position has been used to disqualify lots of other areas of knowledge which are deemed not to be scientific just because they haven't been formalised. So I wonder, is it possible to loosen or weaken the criterion of scientificity in order to guarantee the same degree of insuperable objective validity to biological, geological, and even zoological discourse, without saying that science is purely about a set of stipulative conventions and criteria of legitimation? And I think this is a really profound epistemological problem, and that's why I want to refuse the idea that Kant definitively resolved the epistemological problematic. Kant gave a bad answer, it's not a satisfactory answer, because of what we know about the contingency of thought and consciousness. We know that thought and consciousness are not ineliminable features of reality, and that reality would have many of the same characteristics even if thought were not there. As Steven Jay Gould said, if the dinosaurs hadn't been wiped out by whatever wiped them out, they would have carried on, evolution would have followed some other trajectory, in which consciousness and all those characteristics and peculiar cognitive prowesses exhibited by sentient creatures would simply never have come into existence, and yet reality would have been the way it is. So I want to generalise, I want to be able to say that we can describe a non-human world, or the inhuman world, without mathematics. Because if you cast doubts upon the objectivity of these non-mathematical discourses, then it seems a very … well, it's a concession that I'm not willing to make, because it simply seems to open the door to all sorts of obscurantism, which I think really need to be exterminated.

Presentation by Iain Hamilton Grant

The basic thing I want to talk about is the philosophical problem of nature, and I think this is a springboard for speculation – not opportunistically, but necessarily. I think that if philosophy of nature is followed consistently it entails that speculation becomes necessary, as the only means not of assessing the *access* that we have, but of the *production* of thought.

I'll start from two things that I think everyone would accept and see if we can work outwards from there. I think that, unless you're some kind of convinced dualist, it's absolutely necessary that we accept that there's something prior to thinking, and that there are several layers of dependency amongst what is prior to thinking. It's not just one thing, it's an entire complex series of events. Now we could articulate that by means of some form of causation. We could try to establish, as it were, a direct line between the event we're trying to analyse, the event we're trying to account for in naturalistic terms, and all the causes that might have contributed toward its production, and so on. Such a task is inexhaustible in principle, not merely in fact. It's inexhaustible in principle because the conditions that support the event that's produced also support the production of other events. So if we accept that there are naturalistic grounds for the production of thought, then we have to accept that the naturalistic grounds for the production of thought are not themselves evident in thought except in so far as thought is regarded as part of nature.

So that's the starting point, and I take this to be Schelling's central contribution to philosophy. Schelling, of course, is known as a transition engine. He was a sort of facilitator, a go-between, for philosophical history. He sits between Fichte – who we all equally understand because, after all, Fichte talks about ethics – and Hegel – who no one understood but who everyone would like to. Schelling had neither of these benefits nor deficits, and in consequence, no one could understand him nor wished to! However, Schelling also produced this monumental series of works on the philosophy of nature, this extraordinary series of overtly speculative works – and when I say that, there's partially a descriptive element here. It's like a genre of writing, at one level. That is to say, the commitment to getting it down as it's coming out, is not merely that of a poet under inspiration – it's also an ideational requirement, really. If the thought as it's happening is to have any impact whatsoever on the world in which it's happening, then it's absolutely necessary that it be got down. So if you look at Schelling's output, it's hideous, it's absolutely frightening. No wonder people hated his guts: he was writing six books a year – and that's not counting essays and journals edited and so on. It was frightening – he turned out more than a novelist. So there's this extraordinary record of production of works on the philosophy of nature. And to distinguish the philosophy of nature as Schelling propounds it or explicates it successively, again and again – and not always in the same way or according to central shared principles – it's convenient to call it 'speculative physics', as indeed he did in the journal he edited under that name, the *Journal of Speculative Physics*. I don't know about you, but the very idea of combining those two things seems an absolute recipe for heaven on Earth. This is building particle accelerators that cost billions, that bankrupt countries, sinking great tunnels into the centre of mountains in order to capture sunlight from aeons ago, starlight from aeons ago – this is speculative physics. So the combination isn't at all strange to us at one level, but at another level it's strange to see it coming out of a philosopher's works.

So those really are the two things. Speculative physics: what is entailed, on the one hand, vis-à-vis the nature of philosophy; and on the other, what it entails for the nature of thought. Those are the two areas I'm particularly interested in. And the reason I think these are significant – beyond the fact that they happen to interest me, which isn't significant – the reason I think these are interesting at all is that they present us with an idealism which is wholly and utterly different. And to illustrate this I'm going to cite, paradoxically, Bernard Bosanquet. I'm very concerned to show that idealism, as it were, doesn't look like we think it does. I'm very concerned that we see and acknowledge this to be the case, because the speculative tools that it has built into it are immense. This is from a book that Bosanquet wrote called *Logic, or the Morphology of Knowledge*. It's a book on logic. One question is, why are the idealists so fascinated by logic? Why are they all experimenters in logic? Why do we get vast tomes, repeatedly, from idealists on logic? There are many possible answers to this, and I'll come to one of them later. But this is what Bosanquet has to say at the very conclusion of his book. Upon starting it out he has two epigrams, one from Hegel, from the *Science of Logic*, the other from Darwin, from *The Origin of Species*, and his avowed aim is to bring these two things together. I won't use the phrase 'evolutionary epistemology', although obviously there's a certain kinship between these strategies

– but there is certainly something about knowledge that entails that it is evolutionary, if it is knowledge of nature. This is what he has to say:

> In knowledge, the universe reveals itself in a special shape which reposes on its own nature as a whole and is *pro tanto* proof against contradiction. The detail that the universe presents in the form of cognition is true *of* the universe, although falling within it, because the universe *qua* object of cognition, in it's self-maintenance against self-contradiction, in that form, shows that it must take the detailed shape it does and no other. And to know it is to endow it with that form, making the given more and more of itself.[5]

Now this has got a lot in it, but the two things to pull out of it are: 1) the fact that there is, again, this nature that precedes the production of logic – and incidentally, in the quote from the *Science of Logic*, is Hegel talking about, you know, how evolution is significant if and only if we can account for the production of the syllogism in evolutionary terms, which is fair enough, really: a true philosopher, there. But this is not Bosanquet's project. He thinks that the universe is actually manifesting logical laws and their expression is largely indifferent. What we will find is that nature does behave in this way. So there's this *prius*, this 'firstness', preceding, as it were, the production of the laws of logic in so far as they are *overt* laws of logic and are articulated by ourselves or some variant thereof. 'To know it is to endow it with that form', Bosanquet says; and that form is the form it necessarily has in so far as it is the universe, manifesting itself and maintaining itself against self-contradiction. There is a reality to the law of non-contradiction. It's not merely a formal thing, it derives from natural history. There is a production of non-contradiction which takes place constantly throughout the production of nature. The productivity of these logical constants can be measured in terms of existence. Beings are everywhere the fruit of the stated mechanism. It would be one and the same thing if we discovered any other law of nature. All that's happening here, all that Bosanquet is suggesting, is that the grounds for our being able to have a law of non-contradiction are supplied, as they are for all thought or all systems of thought, *not* from the ether, *not* from some non-physical cause, but from nature.

---

[5] B. Bosanquet, *Logic, or the Morphology of Knowledge* (Oxford: OUP, 1911), Vol. II, 322.

Now if we accept that, it seems to me that idealism is committed to a realism about all things, a realism that applies equally to nature and to the Idea. And in general terms I think this is true, I think this is what all idealism in fact does: it approximates, more or less. If you look at Plato, who is often regarded as the very archetype of the 'two-worlds' metaphysician, what does he say? He says fundamentally that becoming is caused by the Idea which it can never be but can only approximate. This is a physics, this is fundamentally a physics. The Idea is a content-free point that denies accessibility, that determines, as it were, the chaos around it to be chaos around it. Why? Because the chaos around it cannot be what it is, because it is the only self-identical thing there is. There are several Ideas of course, so it's not just one, despite certain splits toward the end of the *Republic*.

Okay, so I think basically there are grounds to assume that idealism is realism about nature coupled with realism

Iain Hamilton Grant

about an Idea. In terms of the situation in which we find ourselves today, my question really is: does this or does this not, as it seemed to at the turn of the nineteenth century, provide an exit from the strictures of Kantianism? Clearly, I think it does, and it does so by denying that interiority plays any role whatsoever. The Idea is external to the thought that has it, the thought is external to the thinker that has it, the thinker is external to the nature that produces both the thinker and the thought and the Idea. There are a series of exteriorities between thinker, thought, Idea, the various strata of the nature necessary to produce that event – necessary but not sufficient, it should be stressed. So you can't say that this and only this nature could produce that event, but we can say that it's necessary. I've said a little about why, and that's a huge problem actually. It's simply that the problem of ground, naturalistically understood, presents us with a tremendous series of problems. If it is the case that the Idea is exterior to the thinking, the thinking is exterior to the thinker, and the thinker is exterior to the nature that produced it, then, inevitably, we no longer have a series of interiorities within which it's possible for anyone to recognise themselves in the production of their thoughts. It's simply a banal accident that we know what it feels like to have thoughts. That is not particularly significant. What's significant is the thought. The thought is the product, and of course there are events taking place that surround that thought. It's very difficult to imagine, as I said, that what's necessary for the production of a particular event in nature is sufficient for the production of *that* and only that event. In other words, we have no reason whatsoever to assume that our perception of our own interiority guarantees that that interiority is somehow reproduced in reality. It just isn't: that the Ideas are separate from the thinker that thinks them, the thinker that thinks them is separate from the thinking that he or she thinks, and the separateness of the thinker from the nature that *necessarily* produced it isn't sufficient *on its own* to produce it, seems to me to guarantee that.

So that's idealism. What does idealism therefore offer speculation? Why does it make it necessary? There are two reasons why, and I'm really going to concentrate on one – and this is part of an answer to one of the questions that Ray asked earlier concerning, 'how do you arrest the process of production, as it were?', 'how does the product intervene, as it were, in a process of production such that in some sense the process of production has an outcome?', because without that surely it isn't a process of production. So is this a dualism of principles or is there something else going on there? I'll begin this with a re-articulation of what Schelling did to Kant. This is brutal. If thought had an anatomy, and if a thinker were to have done this to an anatomy, then the owner of that anatomy would be completely dismembered. In other words, this is Schelling being the Furies chasing after Orestes in the forest. He rends Kant to shreds. He takes the *a priori* and the *a posteriori* and totally inverts their purpose. The *a priori* is intended to guarantee that prior to the production of any thought, there are certain laws in place of that thought that entail that that thought and only that thought can be legitimate within the sphere it's being thought. Schelling turns it around and says, 'No this is not *a priori*, this is a *prius*. It's firstness'. *A posteriori*, Kant wants to claim, is a matter of almost total indifference. Any science that studies, for example, as chemistry does, 'mere' sensible *a posteriori* evidences, is basically mistaking the product for the law that produced it, and is therefore pointless, not really a science but a cataloguing exercise – something, incidentally, that both Hegel and Darwin complain about in the epigrams in Bosanquet's book, this 'cataloguing exercise'. The *posterius* and the *prius* for Schelling – far from representing this divide between what is *a priori* true for all knowledge, for all knowing, and what is *a posteriori* going to be given, that *a priori* once granted – is to say that this is simply a firstness and secondness that belongs to a generative program. The firstness is firstness not merely by the nature of thought but by the nature of what it is that thought is. In other words, it's not an internal problem of thought that there is firstness – apriority, if you like – it's rather a problem of nature that there is a problem, that there is a question or an apriority. The *a priori* is nature. Unless there were a nature there would be no thinking, I think we can agree. If there were no nature there would be no thinking. The *prius* of thinking is necessarily nature. But the *prius* never goes, is never a *prius*, unless there's a *posterius* for it to be *prius* to. In consequence, the product and the productivity, the *posterius* and the *prius*, are two co-present and constant elements in the articulation of process. It's simple. It's a formal nugget at one level, but at another level, it's actually the way in which firstness and secondness – time, in other words, or its production – becomes particular, becomes particular entities, becomes particular thoughts, whatever kind of entities are produced down the line. All we have is sequencing, and the sequence is *prius* and *posterius*. But a *posterius* can never, no matter what it is, capture the sum total of the causes of its production. This applies to physical entities, it applies to mountains: Imagine a mountain trying to contain within itself and catalogue, lay out, merely to lay out and catalogue, all the elements that went into its production. '4.5 billion years. By God, that's a long life', says the mountain. 'How much further have we got to go? Only another 10 billion years, till we get back to the point where I catalogue all the events that are necessary to my production', and so on. It's as important to the production of physical entities, such as is commonly understood, as it is to thought. What is it that happens when thought pretends to chase its own tail? – the Ourobouros diagram from the front of the Macmillan edition of Kemp

Smith's translation of Kant's first *Critique*. What is it that happens when thought tries to catch its own tail, tries to trap its own conditions of production in its product? First of all, it can't happen, because, as for the mountain, the conditions of the production of the thought are simply far too extensive for it to be in principle possible for a thought to recover them. So there's a necessary asymmetry, if you like, between thought and what precedes it, and it's this asymmetry which means that thought is always different from what precedes it and always at the same time requires what precedes it as its necessary ground – necessary but not sufficient. So there we have a process of generation that's understood as one then the next, that is demonstrated, if you like, by the incapacity of thought or mountains, by the lithic or the noetic, to go back and to recover its conditions of production. It's simply not doable.

So that is the beginning of a problem, the beginning of a naturalistic interpretation, a speculative physical interpretation, of the question of ground, of the problem of ground, which, it seems to me, is a problem that we're all addressing. Several consequences flow from it which it seems to me are worth explicating, not in so far as they relate necessarily to this project but in so far as they relate, I think, to speculation in general. I would like to make certain claims, in other words: I would like to make the claim that speculation is entailed by natural productivity. We don't have, in other words, the comfort zone of an interiority which really masks an impossible reflex. We don't have that comfort zone to slip back into, and to say to ourselves, 'Ah, look, we have recovered the totality of the conditions under which thought is possible, and *only* possible'. We don't have that comfort zone, that interiority, and that's one reason why speculation's entailed … It also means something very bizarre epistemically at a quite mundane level, at the level of reference. What is it that happens when we have thoughts about things? Two things happen: there are things and there are thoughts. What's the basis of their relation? Well, the thought that specifically occurs at that point is the means by which they are related, and that if there is no other body of reference, are we talking about a world? No, the world's talking. Now, the question therefore becomes: If the world talks, if the world is articulate, and if, that is, nature thinks – and however many strata we want to place in between the agent and its product is fine by me, well, there ought to be loads … however many strata we want to place between the agent and its product, between the thinker and the thought is fine – but it seems to me that if nature thinks, then it follows that nature thinks just as nature 'mountains' or nature 'rivers' or nature 'planetises', or what have you. These things are the same to all intents and purposes. In other words, there are new products every time there are thoughts, which creates the problem of ground. And as I see it, the problem as it presents itself through these lenses, seems to me to focus on a single question: Are there one or many grounds? If there is one ground for example, the law of non-contradiction, such as Bosanquet espouses, being a fruit of nature – if there is one ground, then all of the fruits of nature can be related to that ground. Necessarily? Certainly. But sufficiently, no. If there is more than one ground, if there is ground every time there is event, then that becomes a question of what job it is that the ground is doing. Is the ground a *prius* or a *posterius*? And as a product, an entity, it must be *posterius*. So the reformulation of the question of ground, it seems to me, is the means by which we can guarantee a consistent speculation concerning the origins of thought as much of as the origins of stones. And that's where I'll stop and open it up …

*

Alberto Toscano: What's not entirely clear to me when we talk about realism is the particular relationship being proposed between thought, consciousness, cognition, and various other terms. Because on one level, this Schellengian idea that nature thinks in the same sense that nature planetises or blossoms or does whatever – that seems to give thought a kind of substantiality and materiality of sorts, although it's not entirely clear how one would define it. On the other hand, for instance, when Ray was speaking about a science of cognition, one of the things that's very striking in a lot of work being done on these issues is precisely a tendency towards something like a substrate-independent or matter-independent notion of thought, whereby indeed thought would be something that is perfectly compatible with a kind of inhuman horizon, inasmuch as it's not by any means necessarily individuated over human beings or intellects and so on. So in a sense it would be sort of radical anti-Kantianism that would also involve avoiding anchoring thought in any form of subjectivity. And so, I suppose, one of the issues is not just the question about a realist epistemology or epistemology's relationship to realism, but it's also a question about whether speculative realism is also a realism about thought. And if it's a realism about thought, does it necessarily depend on thinking of thought as something that has a substantiality and materiality? Another possible option would be to be a formalist about thought. I'm thinking, for instance, of the Churchlands. There's a point in one of the debates where they say, 'Well, if thought is to some extent or another understandable as a type of formalism' – you know, they talk about pattern activation vectors, etc. – 'then why can't thought be instantiated over a social collectivity or a network of computers or indeed whatever other assemblage or entity you might find?' And this seems to me very important vis-à-vis science, because if we start talking about science and realism and then act as if scientific discoveries take place in the sense of individuated human thought, it seems that the entire process of the generation of scientific statements is completely misrepresented. Because it seems to say that whatever statements are being produced about quarks or about galaxies and so on, involve the capacity of a single human scientist to think about the cosmos – which seems a totally farcical scenario about how science operates. It seems like a false epistemological scenario. So I was wondering – I mean, obviously these are a broad set of questions – but vis-à-vis this kind of Schellingian line, what is the status of the reality of thought? Is it some form of substance?

IHG: I'd like to start from one of the points you make, because in the terms in which you put it I think the interesting point is this: If this is true, if there is an unrelated *prius* and *posterius* in the production of thought, and if this has the effect of making the thought particular to its conditions of production but incapable of reflexively recovering those conditions, then we are condemned to a complete particularity that would seem, on the face of it, to deny the prospect of collective work. So it certainly would make, for example, subatomic physics impossible. There would be no prospect whatsoever of collective work. So I'd like to start from an almost sociological point of view. I mean, it seems to me that clearly there is sufficient consistency across a range of individuals in laboratories and so on and so forth, to generate the sort of work that was done in early sociology. It seems there is, obviously, consistency. Theory itself, the very idea that there are theories, is dependent on some kind of consistency being reached that makes it irrelevant what the conditions of the production of thought are.

AT: In the individual?

IHG: In the individual, yeah. So the question is how this happens. And it seems to me that this is why the idealists are fascinated by logic. If it is true that we have nothing to go on other than the thoughts being produced, then the demand that the relations between thought, things, and so on be formalised becomes an imperative. It's the only way this could possibly happen. This is something I was thinking about while reading what you had to say, Quentin, on formalism, on mathematics, and about the *signe dépourvu du sens*. This seems to me to be necessary if there is going to be any kind of communication between sciences such that a programme becomes possible. However, what does that mean? It means, in effect, that there must be produced a series of reproducible patterns. The whole question ceases to be, therefore, a question of the conditions of production and starts being a question of the kinds of products required. The fact that they are available could of course then be used to trigger a rekindling of the transcendental. To some extent, the criterion of utility attaching to maintaining a scientifically realist epistemology, as it were, gives the game away here. We can't recover the conditions of its production such that it's possible for us to say, 'Well we know this because …', and so on. We might be able to do this in one particular case, but there will always be others, other cases that produce other thoughts, and that's why it becomes necessarily a question of ground once again. Is there one ground for all patterns, or are there several grounds for several patterns? In other words, how malleable are logics? How many possible formalisations are there? That seems to me the question that nature poses to thought.

Ali Alizadeh: One word which is not being mentioned so often here is 'cognition'. You talk about consciousness and you want to talk about the difference between the ideal and nature, but how far would it take us away from Kantianism and transcendental philosophy altogether if we tried to abolish completely the synthetic unity of apperception? That's kind of what Ray mentioned as well. There is the difference between thought and thinker, as you said, and the difference between thought and Idea, but the problem is the implicit evolutionary theory here. And if you go for an evolutionary theory the move from nature to thought and from cognition to thought has to be gradual, it has to be linear, but we cannot really trace these trajectories all the way back from humans, who think self-consciously, to all the forms of inorganic life from which we emerged. But we do know that the difference between cognition and thought is disjunctive. It's a difference in quality. So that's the problem: Kant was not interested in finding the totality of the conditions of the production of thought, he was interested in finding the conditions of the possibility of cognition, whereas you're just interested in the former.

IHG: So Kant was also interested in necessary but not sufficient conditions also, as it were, in that regard: not the conditions of the production of this thought here and now but rather the necessary conditions if there is thought, the form it must take, and so on. Yeah, I agree, and I don't think, as it were, that there is no attraction to the transcendental. I don't think that the idea that Kant was just gloriously wrong and how we laughed when we look back and we think, 'Oh God, the eighteenth century, they were so dumb!' It's not really that. There is such a powerful attraction to the domain of the transcendental, the domain that is anchored by – not that anchors, and this is crucial – but is anchored *by* the transcendental unity of apperception. There is an attraction there, because it presupposes a domain, the one domain in all being, where everything can be ruled by what Freud called 'the omnipotence of thought', where it's sufficient for me to think to be able to determine what goes on. So I think, yeah, that aspect of Kantianism, that reason why Kantianism, or the transcendental apparatus in Kantianism, has become so embedded in our philosophical practice, is because of its powerful attractiveness – a domain wherein it's possible for thought to legislate for itself, not for others, not for anything outside itself, and not to be legislated to by anything outside itself. The problem is, it's impossible. There must be something that produces this, this must come from somewhere, unless of course it's parachuted in from Venus. It could be a Venusian Richard Rorty, I suppose, who legislates what we think. Thought comes from somewhere, and the somewhere it comes from is nature. To that extent, it's no longer going to be possible to consider that the transcendental unity of apperception is responsible for the transcendental. Rather, the transcendental is responsible for the unity of apperception. So, regard that as a product rather than the producer of the field. It's not the autonomous judge, it's rather the heteronomous satellite of the transcendental, if you like, turned around on the basis of a naturalism about how thought got here at all. And we simply have to give up the illusion that the domain of thinking that we call reflection is coextensive with the domain of thinking *tout court*, as it were. So, I think – although abrupt and hideous – that's what's necessary.

AT: Can I just follow up on that briefly? On what grounds, in the step beyond the critique of Kantianism, does one want to make the argument that the conditions, let's say, of the *genesis* of thought, however defined, are relevant to the *conditions of possibility* of thought? For instance, if you have a kind of substrate-independent notion of what are the formal or formalisable conditions for thinking, however defined, then whether it's arrived at by a particular genetic lineage, or whether it's artificially produced, etc., the argument would be that ... well, isn't it the case that if the Kantian project at its core remains persuasive, then in a sense whether it's evolutionary or machinic or whatever other genetic process is to some extent irrelevant? … I mean, wouldn't that be the reply, to say that it seems to beg the question to say that somehow genesis is necessary to understand the immanent conditions of the possibility of thought? Unless obviously you totally pluralise thought in a way in which the thinking of the Venusian and our thinking are only the same thinking by convention rather than by a set of formal conditions.

IHG: Yes, one thing the transcendental entails, epistemically and metaphysically, is that it gives us license to be able to think a finitude of possible types of knowledge. If we don't have that, if we don't have the transcendental to rely on, then either we find some other mechanism that does the job without entailing that this finitude is active fundamentally in a subject or we just haven't got it.

AT: So there's no closure to whatever we might understand by thought?

IHG: No, no, no … But I think that must be the case if we hold that time is to some extent involved in the production of nature. I put it that way around. I don't say that if we hold that, you know, neo-Darwinism is the correct account of genetic transfer, then, etc. … I don't put it that way around. If there is time involved in the production of nature, then that time is the reason why the particular aspect of nature that happens to think, as it were, is what it is. It's necessary that it is, but its sufficiency is always in question. And what are the mechanisms by which it can be assessed? Well, inevitably, third-party ones. It can't be done by reflection.

There is the possibility of a morphology of thought, as it were, where we look at the patterns. This is the suggestion that Whitehead made years ago, and there are interesting suggestions in contemporary logical formalisms – for example, Graham Priest. There's a thing he's working on, a thing called 'dialetheism', which is basically a logic that makes self-contradictory propositions coherent elements of a formal system.[6] He says that two properties are contradictory – one is closure, the other is transcendence – and neither of them can be reduced, one to the other, and both are operative. This is a system which is entirely inconsistent but generates consistent systems. So the question of patterns might become more important. But then we don't have to ask the questions, or we're not tempted in the same ways, to ask the questions about 'what is the horizon of the possibility of these patterns', because the horizon of nature is possibilizing them – you know, nature is the reason.

Graham Harman: I'll save some bits for my comments later, but Ray already alluded to a principle of 'retardation' in your book: so you have a primal flux or becoming that's pre-individual in some way, and retardation is what makes it crystallise into individual things such as rivers and mountains. Now, of course, we've seen this in other philosophers, where it's the human that's the retarding principle. So, for example, in Bergson, if not for humans time would go like that [*snaps fingers*]. And for the early Levinas: if it weren't for the human subject, being would be an *apeiron*. It would be a rumbling *il y a*, and it's only the human that breaks it into parts. But obviously you don't want to do that because you're a realist. So it can't be the human who does all the work. So how exactly is this retardation – I know it's a tough question – but what are some of the ideas you have about how the flux can be retarded to give rise to individual shapes?

---

[6] G. Priest, *Beyond the Limits of Thought* (2nd edition, Oxford: Clarendon, 2002).

IHG: It generally happens that when asked questions of this nature, the answer will strike me in about three days' time! But this in a sense illustrates the answer that I'm going to give now, which is, it seems to me, that if there is production there is product and vice versa, and there is no production if there is no product. And instead, therefore, of thinking of the question of how there is this substrate where the mobile is static, where it acquires form, we think about, you know, this is the conjunction of product-production, as the kernel of all possible production. Then, to some extent, the question disappears. Now I know that doesn't answer the question, so it's a solution that evidently I haven't thought through.

Peter Hallward: This is a way of going back to Alberto's question, but you said at one point that nature talks, or nature thinks, and I just wanted to know what that means, exactly. What does that add to our understanding of linguistics or the symbolic or the semiotic or, you know, conventional accounts of how language works, by saying that it's nature that's doing the speaking? How does that sharpen or inflect a research agenda in a way that people who work on linguistics, for example, might understand?

IHG: Two things, I suppose. One is, if we're talking about purely symbolic language, then clearly the answer to that question belongs to the answer I made to Alberto concerning patterns, concerning shared languages, a shared symbolism. But that is possible only on condition that the symbolism has no reference. The alternative would be that there is a way of accounting for the production of linguistic units in terms of referential signs. So you need to place the cart before the horse to some extent in so far as you're asking: Given that signs have this property of reference, how is it they get there; was it the natural production of reference, and so on? And this suggests that reference is an essential property of signs. But the principle I take Schelling to be espousing – and of course the possibilities for error are immense, not least because Schelling and consistency were only sometimes bedfellows – is quite simply that if, when it comes down to it, there is a process, a necessary process of nature, culminating in a particular product, and there's no alternative to that view, unless we accept some form of dualism, then what we can accept as being produced in this way exists by virtue of it. The ground is provided by nature. The production of anything else has to be simply accounted for in terms of abstract languages. So the abstract elements of it have their ground, as Bosanquet suggests, in nature. The question is, how many possible formalisms are there? How many possible abstract languages are there? – not really how this particular abstract language can be used to make, as it were, referential sense of a body of natural language, and how speakers use it. So I think the question may be the wrong way around, and that's how I would respond. Although one of the things which interests me, which I think is not just interesting but imperative, is to find ways of conjoining philosophical work with all the sciences. If idealism becomes an operating principle of any sort whatsoever, if it is true, there's nothing which can be ruled out *a priori*. And all the sciences become imperative, in the form of this idealism, and no-one can do all of the sciences. Therefore it becomes a cooperative labour. Therefore the question that Alberto's raising, and which I think you're raising just now, becomes imperative. But we can't, I think, do that so long as we do it through lenses that presuppose exactly what's being explained, as it were. That's a disappointing answer, I'm sorry …

Dustin McWherter: I have a question that also kind of follows up on Alberto's question about the ontological status of thought, but also a question about how this plays out in your book. In the *System of Transcendental Idealism*, Schelling has an explicitly epistemological agenda, and it seems to me that that's elided a bit in your book, despite the brilliance with which that work is otherwise interpreted and explicated. So, how would you handle Schelling's epistemological agenda in the *System of Transcendental Idealism*? And furthermore, it seems as though, in that reading of the *System of Transcendental Idealism*, you construe ideation as simply a regional phenomenon in nature: Nature becomes an object to itself through organisms that can think. So it's merely regional; thought's not everywhere. But at other times it seems as though you're speaking of Ideas in the Platonic sense, as things that exist independently of thinkers – and I think this is a reflection of an inconsistency in Schelling's philosophical trajectory. So, those are my two questions: what about the epistemological agenda of the *System of Transcendental Idealism*? And, is there a kind of oscillation in your book between the regionality of ideation and a kind of universality?

IHG: To take the second question first, it's fascinating, I suspect my answer to this would have been different a few months ago. But I think that what's going on is effectively that thought isn't everywhere all at once, but there are thoughts, wherever, at various times, and there's no region for which we can rule out thought occurring prospectively at any particular point. However, it remains true that thought does happen at such and such locations. That's the bridge, as it were, between the nature of thought and the thinking doing it – which is the inversion that Schelling explicitly undertakes in the epistemological work that he does in *System of Transcendental Idealism* – but it's an inversion premised precisely on the unrecoverability of the conditions of genesis of thought. So, he says, for example, 'the lamp of knowledge points only forwards'. This lovely line provoked a great deal of consideration on my part, and I thought – well, actually this is definitely true. And there is no prospect, really, of it being otherwise. Even the reflexive recovery of the conditions of production of the thought that is pointing only forwards would entail a lapse of time. Whatever comes after it would be a second, with the lamp shining in one direction rather than another as its *prius*, *but* that gives determinacy at the same time as it denies the possibility of recovery. And so it's the question of determinacy which I think is core to the epistemological project that Schelling pursues. This is the vexed question of the presumed identity between nature-philosophy on the one hand and the transcendental philosophy on the other. This is why, I think, Schelling says at the outset of the *System of Transcendental Idealism* that it's necessary to consider this as an adjunct, to consider it to be simply true that there's always a double series involved in thinking about thought, because it tends to be that they're closely related, I take it, in time, although I'm not sure. I'm not satisfied with that answer. I mean, it seems phenomenologically apt, but whether it's got any basis in the principles he offers for a consistent priority and posteriority, I don't know, or the *prius* … there are ways it can be worked out, perhaps. But the final thing, therefore, is the question of identity, which comes back to the question of the Ideas, and why the Ideas might be one and at the same time many, and yet the thinking of them may be potentially everywhere, and so on. This is really the core of the problem. Is Schelling a Platonist, a neo-Platonist, or some form of hyper-Platonist? So long as the 'Good beyond being', as it were, is not taken as being the entire anchor to the system of Ideas, which structure is then reproduced here on Earth. Schelling's conception of identity seems to me to go a long way towards explaining the possible relations between Idea and thought. He actually makes this explicit in *Presentation of My System* and *Further Presentation of My System*. On the one hand there are Ideas which are identical. *They* are identical; but not to the things they are ideas *of*. They're not ideas *of* anything – they're Ideas, and their identity is their being as Idea, fullstop. And that means that everything which is not them is in chaos, in flux, and so on. So the means by which to relate the Idea to the thinking is the concept. The concept is a partial grasp of the Idea, or a finite and differentiating grasp of an infinite identity. That's his description of it, which seems to me to do quite a better job than the 'double series' claim. In other words, if the proto-phenomenology of the double series is an explanation of an epistemology, it seems to me not as good as the neo-Platonic exposition by way of the difference between concepts and Idea in the later work. But what we have not got to deal with is an absolute identity of thought here and being there, in this hideous symmetrical way in which Hegel will pretend, and which bad readers of Parmenides always maintain.

Noortje Marres: This is a partly related but somewhat more general question, regarding realism as an epistemic question, a question of knowledge and of thought. Because listening to your talk, and also Ray's, made me think of other kinds of undoings of Kant in the twentieth century, because that's obviously taken many forms and has been launched on many different occasions. And one of them, I thought, had to do precisely with undoing the primacy of the epistemic. There you get arguments concerning realism as a question that must be taken out of the realm of epistemology if it is to be addressed pertinently, and this shift can take various forms. It can be a shift to historic ontology or a shift to ethics or embodied experience, with various consequences for the type of realism, obviously, that results. But I'm curious how, on the basis of the types of arguments you have presented now, what your position is on this question. Should it be preserved as an epistemic question, or is your mode of arguing actually moving along with this ontologising and making ethical of the question of realism?

IHG: I'm certainly ontologising, certainly *not* ethicising. I think one of the badges by means of which Kantianism is maintained, the reason why it remains a problem despite the various attempts to undo it, is because, all too often, the Good assumes authority over being, and it becomes possible to say things like, 'The universe ought to be…', and this statement is assumed to have philosophical significance. In fact, Fichte says just that. He started with an identity, a realism about, 'Here I am, what do I know about myself? Well, all this accidental stuff, plus I'm free, dammit! … and I'm gonna show it!' And that's the basis of Fichte's realism. He goes to great lengths to demonstrate this, but fundamentally, what he reserves the right thereby to do is to call realism the view that – and here I'm going to cite a passage from Kant – desire consists in being the cause, 'through one's presentations, of the actuality of the objects of those presentations'. It occurs in two places: in the *Critique of Practical Reason* and the *Critique of Judgement*.[7] What that means is that it's simply enough to will or desire it in order that it be, because being is secondary to acting. And that, it seems to me, is simply not true. It's transcendentally adequate only on certain conditions, and those conditions are that the remit of realism is maintained solely within the transcendental field, *i.e.*, solely within the field of possible reflection, so that I can always say, 'Oh well, I know I got run over by a bus, and I know that looks like the revenge of the not-I, but in fact I willed it thus!', which is what Nietzsche said, in effect. So I think there can be no liberality at that level, and realism can't be regionalised, as it were, nor said to be realism if it is dependent on the willed suppression of some external condition. An ethical realism is precisely not a realism, in the same way that a political realism is not a realism. In the same way, in fact – and I know this is contentious, but it seems to me a point that needs to be made – a *critical* materialism is *not* a materialism. Fundamentally, it's a materialism oriented, driven, steered, designed, by critique. In other words, it's a theory of matter held by people with some use for certain bits of it and none for others. How is it possible for critical materialism to think that there can be a difference between what *matters* and crude *matter*, you know, things like plants? So I think that there can't be any liberality at that level, that would be my answer. And the very fact that such positions are perpetuated is the reason why this needs to be done again.

---

[7] *Ak*.V 9n. and *Ak*.V 177n., respectively.

GH: I can guess what you think of Marxist materialism.

IHG: Love it! No, it's simply wrong. The idea that it's possible to invoke a diminished realm, as it were, for matter and to condemn whatever does not fulfil the economic, teleological purposes of certain types of agents to a sphere of 'merely crude matter', where it has absolutely no effects whatsoever, where it's left to one side of the philosophical and the political problem, seems to me a recipe for disaster. If you're trying to do politics, if you're trying to work out, 'we need to do *x*, how are we going to do *x*, we need a strategy', and so on. What's the first thing you do? You take account of the environment, and so on. What's the first thing critical materialism does? 'I want a theory of matter, what am I going to do? I know, I'll ignore half of it'. That's just not good metaphysics, fundamentally. It's not a good way of approaching reality, it seems to me.

PH: But what about cases where you *do* will something to be true, though, or to be the case? I mean, just banally, holding a promise, making a commitment. There are cases in which something comes to be because you will it so, and politics would be completely disarmed if you lost that.

IHG: There's the Spinozist response to that: what I think of as my freedom is my incapacity to explain the cause of the event that I'm trying to describe. I move my arm because I will it so, or do I just not know the causes of my arm moving? That's the Spinozist answer …

PH: And like I said, that disarms, well, that *is* the disarming of politics.

IHG: Yeah, yeah it is. I think … fundamentally it seems to be a question about consistency of effects, at one level. It's possible that a series of actions can be maintained despite having, let's say, punctual conditions of production. So there seems to be a consistency of events, and they're all tending in one direction. I want to raise my arm because I want the bus to stop. So I stick my arm out and the bus stops – a triumph for transcendentalism! I have achieved the stopping of the bus by means of my will alone. Let's say that happens. It really does seem to be about a question of consistency, and the problem from the perspective I come from is how to explain the consistency, and I do acknowledge that's a problem. But do we explain it any more by saying that it's an act of will? I don't think so. I think the reason we move our arms is because we have arms to move, first and foremost, and because there are certain contours of the world that make that a possible gesture and a significant gesture: naturalistically possible and socially practical. It has outcomes. But the question of whether we should hold ontology ransom to political expediency seems to precisely re-present the problem of transcendentalism, in so far as the latter concerns 'what are the spheres of my legitimate autonomy, over what can I legislate?'

AA: Action and will do not only belong to the practical realm of philosophy. They go back to Descartes, in a sense, because will and action are the very necessary elements of thinking itself. Without willing to think there is no thought – so before it becomes the practical element, it's epistemic.

IHG: Again, this is a solution, I think, that's often tried. Let's say we've accepted the point that in order to think I have to will it, yes? And let's say I'm not thinking yet, but I will to think. I will to think, and then comes the thought. How can I will to think prior to the thought that I will to think being there? I can't. So the idea that there is a will that thinks thought for me makes sense if and only if that will is outside of me, is nothing to do with me. So it's not *my* will that causes the thought to occur. If we call it 'will' that presumably serves some additional ontology, some additional metaphysics – Let's say the Fichtean one, which does subsume epistemology, the theoretical under the practical. Let's say that's the aim. Then it begins to make sense to do that, but only given those caveats. Fundamentally, however, I don't think it's true that my thinking is caused by my will. Would that it were! For God's sake, then practical problems like writing papers late at night would disappear!

AA: But you don't have any criteria for the intensity of the receptivity of sense data here – that is, whether or not I'm aware of the intensity of what I'm receiving, reinforcing that data, and that I'm not just receiving it in a kind of semi-unconscious state …

IHG: Yeah, put it in the form of a question: What is the impetus to thought? Where does thought come from? If you can answer that question, then we can say what the source of the thought is. And the necessary answer, I would contend, is that it comes from nature.

Cecile Malaspina: And where does nature come from?

IHG: What's the ground of the ground? – absolutely. Why is there this nature rather than another, and so on? That's the principle of sufficient reason, that's the problem of ground. That's why I think it's an important question.

Ray Brassier: Obviously you claim that so-called transcendental metaphysics says that you can't be compromised by any concessions to folk-psychological superstitions. I wonder, then, what's the status of categories like 'production'? What happens to the conceptual register that you use – that Schelling used – to articulate this kind of transcendental philosophy? Given that transcendental philosophy, or even a nascent speculative materialism, is carried out using the semantic resources of natural language, doesn't there need to be a kind of dialogue between the critical and eliminative dimension of a properly scientific psychology which systematically undermines the viability of these folk-psychological categories, and the project of a transcendental metaphysics? In other words, this is why I think the relationship between ontology and epistemology can't be straightforwardly adjudicated from either side. For instance, imagine a Schellingianism informed by the Churchlands: recasting the categories of speculative metaphysics using the resources of dynamic vector activation patterns. So, doesn't this requirement for a dialogue with eliminativism mean that you have to kind of stipulate a revisability in terms of even the most fundamental conceptual categories you use, such as productivity or production?

IHG: Okay, let's start with the question about the Churchlands. It's not hard, actually, to make the Churchlands into Schellingians. In fact, at the end of Patricia Churchland's *Neurophilosophy* – the biggest manifesto ever written – she says, 'So it is that the brain investigates the brain […] and is changed forever by the knowledge',[8] which seems to me perfectly Schellingian. There's an absolute symmetry there between what she's arguing and what Schelling discusses in his own epistemology. How do you anchor the knowing of things, as an extra product, in the being of those things that you want to know? So there's a new entity in being. That's the way of addressing the problem. So I don't think, philosophically, metaphysically, that there's a problem there. I do think, however, that there's a point when the epistemic demand makes demands on ontology that ontology can't meet, when we have to ask, 'is this a correct epistemological approach?' But that's the way around to do it, I suspect. So, for example, this is the method of eliminativism: I'm investigating an object, call it a car, and this car, it is alleged, drives by itself. Now my job is to explain how it is that the car drives, and at the end of the explanation it should be clear. The false explanations have been gotten rid of and a good explanation put in their place. So, let's say all those criteria have been satisfied, let's say that is achieved. What has the theory achieved at the epistemic level? It's managed to produce exactly that explanation. What's achieved ontologically? It's managed to commit itself to an ontology which requires that things that do not exist exist in order that they be eliminated. So it's ontologically inconsistent but epistemologically necessary. I can see its virtue, or I can see its requirement epistemologically. But the question must be put, I think, the other way around: If we work out what the ontology demands, then that provides a means of working out answers to the differences between good and bad explanations, whatever they might be. My suspicion is that otherwise we find ourselves backed into an unsustainable metaphysics of not-being. You called it a 'dialogue between the critical and the ontological' – but that's exactly what Kant maintains metaphysics should be replaced with, a critical dialogue where fundamentally Reason will have the ultimate say. So I think it really is a one or the other question, at that level. The question becomes, how do we think about the problem of epistemological rectitude without invoking, as it were, the transcendental categories?

PRESENTATION BY GRAHAM HARMAN

Firstly, I'd like to thank Ray Brassier for conceiving of this event and organising it. This all started for me about a year ago, when Ray came back from Paris and he strongly recommended that I read Meillassoux's book, *Après la finitude*, which you should all definitely read. And from there I got into Iain's work, and from reading these works, there are definite points in common, which I've had plenty of opportunity to enjoy over the past year.

'Speculative Realism', first of all, is a very apt title, because realism, of course, is very out of fashion in philosophy. And I think one of the reasons it's out of fashion is that it's considered boring. Realism is the philosophy of the boring people who smack down the imaginative ones and force them to take account of the facts. G.E. Moore supposedly held up his hand and said: here it is, external objects exist. Yes, but that hardly exhausts the field of reality! And as yesterday's Lovecraft conference[9] title indicated, realism is always in some sense *weird*. Realism is about the strangeness in reality that is not projected onto reality by us. It is already there by dint of being real. And so it's a kind of realism without common sense. If you look at the work of all four of us, there's not much common sense in any of it. The conclusions are very strange in all four cases. In Ray's case you have a reductive eliminativism, and you end his book with the husks of burnt-out stars and the meaninglessness of everything. That's not something you usually get in G.E. Moore and those sorts of realists!

---

[9] A one-day conference, 'Weird Realism: Lovecraft and Theory', held under the auspices of Goldsmiths Centre for Cultural Studies on 26 April 2007.

In Iain's book you have a pre-individual dynamic flux that somehow meets with retardations and becomes encrusted into rivers and mountains. In my work you get objects infinitely withdrawing from each other into vacuums and only barely managing to communicate across some sort of qualitative bridge. And of course in Quentin's philosophy you get no causal necessity whatsoever. Everything's pure contingency. These are not the sorts of notions one usually associates with realism. Metaphysics is usually thought to be concerned with wild, speculative sorts of ideas, and speculation is usually not considered a form of realism. You hear 'speculative idealism', not ' speculative realism'. Another obvious common link is a kind of anti-Copernicanism. Kant is still the dominant philosopher of our time. Kant's shadow is over everyone, and many of the attempts to get beyond Kant don't get beyond Kant at all. I think Heidegger is a good example of this. Heidegger's a great example of the 'correlationist', in Meillassoux's sense.[10] Obviously, we all think of Kant as a great philosopher. But that doesn't mean he's not a problem. It doesn't mean that Kant is the right inspiration for us, and in fact, I hold that the Kantian alternatives are now more or less exhausted.

One of the things I did to prepare for this conference is to put each of our names on an index card, and I was shuffling them around on my table in Cairo, trying to group us together in different ways. And you can come up with different combinations in this way, various differences between us despite the shared similarities. I came up with some interesting ones; but if you were going to say what distinguished each of us, I think it's fair to say – and they can contradict me if I'm wrong – that Ray is really the only reductionist or eliminativist, Iain is the only dynamist, I'm the only phenomenologist, and Quentin is the only one opposed to causality *tout court* – there's no chance of any necessary relations between anything in his vision of the world. And you can also see different influences in each case. In Ray's case, I think: Badiou and Laruelle. Those are the two chapters that seem most central to me in his manuscript. And cognitive science, of course. In Iain's case: German Idealism, Deleuze, Bergson, and his own reading of Plato. In my case: Husserl and Heidegger, with a bit of Leibniz and a bit of Latour. And in the case of Meillassoux: Badiou, of course, but also, I see a lot of similarities between him and David Hume in many ways; not only the clarity of his writing style, but even some of the arguments, seem Humean in inspiration.

---

[10] For 'correlationism' see **Collapse** Vol. II (March 2007).

Before I comment on the work of the other three on the panel, maybe I should give a quick summary of my own work. It all started for me with Heidegger. I don't think I was ever quite an orthodox Heideggerian, but I certainly loved Heidegger very much. And early on in my graduate studies, I was focusing on the tool-analysis, the way things hide behind their facades as we use them. And it occurred to me at a certain point fairly early that all of Heidegger boils down to this. There's really just one fundamental opposition that keeps recurring, whether he's talking about being or tools or Dasein or anything else: a constant, monotonous reversal between the hiddenness of things and their visible presence-at-hand. And it started as just a reading of Heidegger, and there wasn't really any metaphysical inclination whatsoever at that point.

What first started doing it for me was when I was writing an article on Levinas a couple years after that, and trying to piece together Levinas's theory of how the human subject breaks up the unity of being and hypostatises it into individual things. And this struck me as so inherently preposterous. I'd never really thought of it that clearly before, but the more you think about it, why should it be that the human subject breaks the world up into parts? This actually has a precursor in the pre-Socratics; it was Anaxagoras, for whom *nous* makes the *apeiron* rotate very quickly, and it starts breaking up into fragments, and so it's mind's fault that the world has parts, and each of the parts contains all the others and mirrors all the others. But you see that in Levinas, too. And I realised I was opposed to that, but I didn't quite have the language to start defining why that was so. Then, for my dissertation – which is now *Tool-Being*,[11] the book – if you look closely at Heidegger's tool-analysis, what he's explicitly saying there is that the floor you're using now, the air you are breathing now, the bodily organs you are using now, tend to remain invisible because you're simply using them. You're not staring at them, you're not creating theories about them. Fine, it's a great concept, arguably one of the great insights of twentieth century philosophy. The equipment tends to remain invisible as long as it's functioning solely as equipment – fine. But that can sound like the old reversal between theory and practice. One of the great things about playing with an idea in your mind for a long time is that you become bored with it after a few years. That's why I think we often make progress, because we have a great idea, then we become bored with it and see its shortcomings – and that's what happened to me. I started realising: this is not going to be anything more than 'practice comes before theory', and 'praxis breaks down when the hammer fails'. It also occurred to me that praxis does not get at the reality of the object any more than theory does – that was the next step. Yes, by staring at this chair I don't exhaust its being, but by sitting in it I also don't exhaust it. There are so many deep layers to the reality of that chair that the human act of sitting is never going to exhaust. Even if humans created the chair, even if only humans see it as a chair, there will still be, I'd say, an infinite number of qualities in the chair itself that cannot be exhausted by any seeing or by any counting. So now I had both theory and practice over here, both on this side. On the other side, the causal relations seem to be happening in the depths. But the problem with causal relations is, you really can't say that inanimate objects exhaust each other either, and this doesn't even really get into the whole panpsychism debate. Fire does not have to be conscious to turn cotton into a caricature. (I always use fire and cotton because that's the great example from Islamic philosophy, which I've read a lot of since moving to Cairo.) The cotton has a scent, a colour, numerous other attributes we can speak of, and they're irrelevant to the fire in those senses. And so, it became to clear to me that as soon as you move away from the idea that the world is a homogeneous unit, as Levinas or Anaxagoras think, then you have a world with many parts. And as soon as you have a world with many parts, they're going to interact. And if they interact they're going to have the same relationship of caricature to each other

---

[11] Graham Harman, *Tool-Being: Heidegger and the Metaphysics of Objects* (Chicago: Open Court, 2002).

Graham Harman

that we have. And reading Whitehead at about the same time really cemented that idea, that you cannot privilege the human relationship to the world of over any other kind of relation. Whitehead's still the best source for that, I think, even better than Leibniz, because for Whitehead it can happen at all different levels and sizes. With Leibniz there's always a privileged caste of substances that are natural, and you can't talk about an international corporation having relations with real things. But for Whitehead you can, and for Latour you also can. So Whitehead was one key, and another key was Zubiri, Xavier Zubiri, a Basque ontologist who studied with Heidegger and Ortega y Gasset, who's not as well known as Whitehead, of course, but who I think is a pivotal twentieth-century thinker. Because his idea is that the essence of the thing is never adequately expressible in terms of any relations or any interactions with it, and so that's where the kind of vacuum-sealed objects withdrawing from all relations came into my work, from Zubiri.

And then what I did in *Tool-Being* was that I more or less showed how a lot of things – Heideggerian concepts such as time and space and referential contexture, and all these things – boiled down to the tool-analysis; that was Chapter 1. In Chapter 2, I took that and used it as a weapon against all the things commentators usually say about Heidegger. In Chapter 3, I simply tried to turn in a more speculative direction. And I can make this short, because the real speculative problem that arises from this immediately is that if you have objects that are incapable of contact, why does anything ever happen? Given that it is in the nature of things to withdraw from all relations, you have a real problem with causation. One thing can't touch another, in any sense at all. And this immediately got me thinking about occasionalism in the history of philosophy, of course, where, before the French you had the Arabs – in Iraq you had the Ash'arite school of theology. And of course this fits a lot more easily in Islam than it does in Christianity, which never had any real occasionalists in the pre-modern period, because for the Muslims, in that period at least, if God sends an innocent man to hell, so be it. God is all-powerful. It doesn't create a paradox of free will, as it did for many Christians. So you see that first in the Arabs. It's not only a threat to God if other entities are creators, in the sense of creating the whole universe – obviously there has to be only one entity that can do that – but things like creating furniture and brewing coffee would also somehow denigrate God's power, if individual agents were able to do this themselves. And so God is there to explain all actions, recreating everything constantly. And although the theology seems a bit outrageous to us now, it's a very profound metaphysical idea, the idea that things cannot relate, inherently, that things-in-themselves are totally sealed off from each other. We see this come back in the seventeenth century in Europe of course, and historians of seventeenth-century philosophy are often extremely finicky about who they allow to be called an occasionalist: just Malebranche, Cordemoy, and maybe a couple of other French names. I see no reason not to expand it to include Descartes, and I would also say Spinoza, and Leibniz, and definitely Berkeley. I take the name occasionalism in a very, very broad sense: any time that individual entities do not have causal power you're giving in to a kind of occasionalism. And then Hume is the important final step. Skepticism in many ways is simply an upside-down occasionalism, and it's no accident that Hume was a great fan of Malebranche. Hume owned Malebranche's books, marked them copiously, and here you have a hardcore theist and there an unrepentant atheist. The connection between them is the fact that in both cases you have the problem of things being unable to relate directly, and the difference of course is that for the occasionalists, in the classical sense, you have independent things in the world that are apart from each other from the start and the question is how they relate. In a sense, with Hume you already have their relations. We're already born into a world where there are habits. Things are linked in my mind already, and the question is only whether they have any existence outside it. So Hume starts with relations, whereas Malebranche starts with substances. I think in both cases the solution is incorrect, because in both cases they're privileging one magical super-entity that is able to create relations where others cannot. So for the occasionalists: 'No one else can do it? Oh, God can do it'. For Hume, my mind does it, my mind creates objects ('bundles') through customary conjunction, creates links.

So, the question is how we can have a form of indirect causation that does not use God as the solution – which would lead us back into the discredited old forms of theological philosophy – and which equally does not use my mind as the solution, which would lead us ultimately to idealism, as Hume eventually did lead us. How do we have a realist version of occasional causation, without laying everything on God? And I coined the term 'vicarious causation'[12] just because whenever I mentioned occasional causation people always laughed – that was the first reaction, and I realised it was hopeless to keep this term for myself! It's too associated with doctrines that have been refuted by undergraduates for the past three hundred years, so I had to invent this new term. So I speak of a vicarious theory of causation; but where does this causation happen? That was a mystery to me for a long time, and the mechanics of it are still a mystery to me. The *Collapse* article is about as far as I've gotten; I've gotten only a little bit further than that. But I got the answer from Husserl, of all people, because what we have in Husserl is a second kind of object. Neither Heidegger nor Husserl are really realists, I would say. They both focused too much on human access to the world over the world itself. But in Heidegger we have these tool-beings, these objects; they're real objects, they withdraw from us, they do things in the world outside of our access to them. What you have in Husserl – which is often confused with Heidegger's own discovery – are the intentional objects. If you read the whole first half of the *Logical Investigations*, after he's done refuting psychologism, his real enemy is British empiricism, and what he is up against is the notion that what we encounter are qualities, and that somehow the qualities are bundled together by us. Somehow the objects are not given for British empiricism. What's given are qualities, and those qualities are fused together by the human subject. That's what the entire phenomenological tradition most opposes, I would say, because in Husserl you have intentional objects. You have this table, which I'm only seeing the top surface of, I'm not seeing the front of, as these people [*indicates audience*] are. I'm not seeing the bottom of it. I could circle around it, crawl beneath it and look up at it. All of these changing perceptions, though, do not lead me to think I'm seeing a different object. I think I'm only seeing different aspects of the same object. This table is not hidden from me like the tool-being of the table, like the real table would be. It's here. I look at it, I see the table. I'm not seeing all aspects of it at once, but I am seeing the table, not just scattered qualities. Furthermore, this table is not the same as the real table in the world, doing its own independent work, because the one I think I see might not exist – hallucinations do occur. And so intentional objects are not the same as real objects, despite what Husserlians always tell me. There was a big fight in Iceland last year with the 'Husserlian mafia' – they tried to tell me that intentional objects are the same as the tools, because they want to say that Husserl discovered everything that Heidegger did eight years earlier. It's not true!

---

[12] See **COLLAPSE** Vol. II, 171-205.

One other point about Husserl: Husserl made another bizarre discovery that no one ever talks about, which is that one object contains others: namely, consciousness. My intentional relationship with the table for Husserl can be viewed as a unit, the relation itself as a whole. Why? Because I can talk about this relation, I can retroactively think about it, I can have other people analyse it for me – because, that is, other phenomenologists can analyse my relationship to the table – and none of those analyses ever exhaust the relation, which is enough to make it an object. That's the definition of the object: not a solid, hard thing, but a thing that has a unified reality that is not exhausted by any relation to it, so that the intention as a whole is one thing. But then within that intention, notice there are two things contained. There's the table and there's I myself, both contained within the intention. And there's an asymmetry here because this table is simply phenomenal; I myself, however, am real. And you can reverse it: if the table's actually encountering me, which might not happen then in that case, when you look at the relation asymmetrically in the other direction, the table is the real object in that case and I am the phenomenal object being reduced by the table to a caricature of myself. I know it sounds strange. But I generalise from there to say causal relations always occur on the inside of a third entity. It's not just something that's true of human consciousness and phenomenology. Containment is what a relationship *is*. 'Relationship' means: a real object meeting a sensual or intentional object on the inside of a third real object. And there are incredible problems trying to work out exactly how this happens. There are paradoxes that arise, and I started putting together the puzzle pieces in *Collapse II* in that article 'On Vicarious Causation'. And that's where the project is today. So I hope that gives some idea of what I'm doing so I can better situate it with respect to the other three, who I think are a very good match for what I'm doing. I think Ray chose exquisitely in this case.

I'll start with Ray since he went first. What is always refreshing for me in dealing with Ray and conversing with Ray is his knowledge of and sympathy for the empirical sciences, which is extremely rare in our discipline. Especially in the case of cognitive science, because, probably like most of you, I grew up in an environment where the name of the Churchlands was always spoken with a wince and a sneer. I don't know the work of the Churchlands nearly as well as Ray does. I just picked up Metzinger and am looking forward to reading that, but I don't know these things that well. So that's extremely refreshing. Ray, like the rest of us, does not want to see the human subject privileged in its relation to the world. The idea that our relation to the world is special could be eliminated, that it is a kind of folk-psychology, perhaps, I agree with him on all that, definitely. The two ways in which we may differ … Ray is something of a reductionist, because you heard his objections to me earlier about the hobbits, and he's mentioned the tooth fairy to me before. These are good objections. Are they really as real as solid physical objects? I'll address that one first. The point is well-taken, and this is a flaw in the Latourian position, I think – the position from which I come. Since I diverged from Heidegger, Latour was one of the first life preservers I grabbed on to, since he treats all objects on an equal footing, and I like that part of him. But I think there is a problem. You have to be able to explain reduction, and the way he does it is from the principle of “irreduction”, which is to say, yes, anything can be reduced to anything else, as long as you do the work to show how it’s related. Now this puts too much of the power in the hands of the human scientist, I think. Isn’t it necessarily the case that some things just *are* inherently reducible to other things? I think that’s probably true, and so I wouldn’t want to go the ‘irreduction’ route. I think there’s got to be a better way to solve this problem.

Ray is also opposed to the ontological difference, which is something I’ve retained as a Heideggerian. I don’t use that term, but for me the ontological difference is the difference between the thing itself and its relation to anything else. Now, I think Ray’s rejection of the ontological difference goes hand in hand with his reductivism, because, for Ray, you wouldn’t need anything hiding behind anything else, right? You see certain things as symptoms or epiphenomena of other things, which are in fact real. Then you get to that real level, and then you try to reach something that’s different from where you started. Now, what I would ask Ray is, how do you avoid what I would call, not naïve realism or speculative realism, but ‘*disappointing* realism’ – my term for Kripke, whom I like very much. Kripke is my favourite analytic philosopher by far. He explodes so much of analytic philosophy, and turns it into metaphysics, by simply saying that Russell and Frege are wrong. A name does not refer to all the qualities we know about a thing, because I can learn that some of the qualities

I thought I knew about you were false and yet I'm still pointing at the same person. So there is something there that I *stipulate* to be you that is deeper than the qualities somehow. And he even criticises Strawson and Searle, who give us the watered down 'cluster theory': 'well, you only have to be right about *most* of the qualities you knew about the person'. But does that mean 51 percent of them, or a group of the most important? And so I follow Kripke in his critical portions, that you have to be pointing at something deeper that is essential and the same, that is not reducible to surface qualities. But the reason I call it 'disappointing realism' is because it ends up being the physical structure of things, for Kripke, that is real about them. So what's real about gold is that it has seventy-nine protons. I find that very disappointing. What's real about each of you is that you had to have the two parents that you had – which, first of all, is genetically false, right? You could get the same DNA, by some outlandish chance, through two different parents. And it just doesn't quite seem like it's my essence, somehow, to have come from those two parents. So, yes, I would like to know if you are committed to such a reductionism. For me, it's easy to escape that problem because I have all these different levels, Latour has all these different levels, and even if we have a problem in showing how things reduce, the reductionist position has the more profound problem of explaining what that final level is that endows something with reality. Is it just the physical structure or is it something more? If it's not a physical structure then you could be in some kind of weird idealism, where you have, I don't know, brain-states floating around … Pan-psychism seems to be coming back in fashion among some of these people. Even rocks and tomatoes have some primitive form of intentionality. So I'd like to know what Ray ends up with as his final stage once eliminativism has succeeded. That would be my question to him.

I'll go on next to Iain – I'm going in the order of the programme. I was cheering him on the whole way as I was reading his book. I am completely sympathetic to the idea that metaphysics and physics are the same, because one of the problems with physics now is that it's not metaphysical *enough*, I would say. It doesn't ever really raise the question, for me, of what causation is, for example. It argues about whether causation is statistical or whether it's retroactively caused by the observer, but it never really gets into the nuts and bolts of what happens when one thing touches another. I think it needs to become more metaphysical, and in 'On Vicarious Causation' I suggest that this is how philosophy can get out of the ghetto. We've been so terrified by the sciences for the past two hundred and twenty years. We find ourselves in this ghetto of human discourse and language and power – probably because we're afraid of stepping onto the level of nature. We're afraid that we don't have the resources, but I think we do. I think in Iain's book you can see there are tools for this that we already have. I'm also very sympathetic to his idea that inversions of Platonism are completely useless, because they keep you trapped in the same two-world theory. So, Nietzsche – great, he flips it over – but then you still have the same opposition between appearance and Platonic Ideas. Another thing I love about Iain's book is that it finally made sense of the *Timaeus* for me. There was a great fad for the *Timaeus* in the 1990s due to Derrida's *chora* essay and, even worse, through John Sallis, which really turned me off! So I never really understood it. Three years ago I had to teach the *Timaeus* because I had to take over the class for someone at the last minute, and I wished he had ordered any other dialogue than the *Timaeus*. But finally, after reading Iain's book, it's starting to become real to me: *Timaeus* is the site of a one-world physics, a physics of the Idea in Plato – it's wonderful. Your critique of Kant, I like that, and you cite Badiou as saying we need to overturn Kant, not Plato. I agree with that. I also completely agree with the idea that life-philosophy is always an alibi. Life-philosophy is an alibi for refusing to deal with the inorganic. Why do people like David Farrell Krell always go straight to life and never talk about rocks? What's so sexy about life? You see, it's an alibi, and it's a way to stay close to the human while claiming that you're going deeper than that somehow. Iain also leans toward anti-eliminativism, as I do in my own temperament, which makes us different from Ray, to some extent. And finally, I think, another thing that unites us, maybe more than the other two panelists, is that we are more ambivalent towards Badiou, I've noticed, although we both respect him. You criticise Badiou for giving us only this alternative of 'number and animal', and say that this is not a real alternative. You point out that it fails to capture the geological and other things, and I would tend to agree with that. And I also miss a philosophy of nature in Badiou. For me, the problem is – as I said in my review of Meillassoux's book in *Philosophy Today*,[13] – is the inconsistent multiple in Badiou really multiple? It doesn't really seem to do anything other than haunt our current count, our current situation. But the proper multiple would actually need to interact apart from the subject. It doesn't seem to me that it does so in Badiou, and that's why I would not call myself a Badiouian, though *Being and Event* is a fantastic work of speculative philosophy, the best one I can think of since *Being and Time*. I really appreciate the ambition of it and many of his strategies for attacking certain things.

---

[13] Graham Harman, 'Quentin Meillassoux: A New French Philosopher', *Philosophy Today*, Volume 51, no. 1, Spring 2007: 104-117.

So those are some of the things we agree on. There's really just one central disagreement between me and Iain, and it's a huge one, and it leads into a disagreement about the history of philosophy. The big difference is that Iain is against what he calls "somatism" and I'm totally in favour of it. For him, philosophy is not about the bodies, it's about a deeper force prior to the bodies from which the bodies emerge. For me it's nothing but objects, there is no pre-individual dynamic flux that surges up into various specific individuals. And I suspect there's some influence of Deleuze here, in this position. The objects themselves don't seem to have the power to interact, it all happens at a deeper level. Now, that leads to a big disagreement about the history of philosophy, because he sees Aristotle as being on the same side as Kant. He sees Aristotelian substance as being on the same side as the Kantian phenomenon, which I wouldn't agree with. There are times when Aristotle refers to substance as equivalent to the *logos*, but I think there are more places where he says the real can never be adequately expressed in a *logos*. So I would never go so far as to say that an Aristotelian chair is the same as my perception of a chair for Kant. I would say Aristotle's one of the good guys if you're a realist. He traditionally has been seen that way, so Iain's making a radical move by saying Aristotle's actually on Kant's side, and Plato's one of us – counterintuitive, but interesting. I would say we need to retain Aristotle on our team. I would say the Aristotelian forms are not mathematical formalisations. They are substantial forms, and substantial forms can hide from the *logos*. In fact they do hide, because the *logos*, I would say, never adequately exhausts them. And I would also oppose Iain and defend product over productivity, which I know is very unfashionable. In recent decades the avant garde has always been about process and not product. I would defend product over process, because I think much of process is lost when the product is created, and you don't need to know the process. Much information is lost. Yes, it's true that causation is productive. This is DeLanda, actually, not Iain, but Iain might have said something like this. Causation is productive because there's always more in the effect than there was in the cause. It's also true that there is less in the effect than there was in the cause, because I think many things about the cause are eliminated from the product. Different processes can yield the same object. But my question to Iain would be: Why not just have objects all the way down? Why do we need to have a unified dynamic nature? And notice he talks about geology, but he never, unlike Latour, talks about technological objects – oil rigs and things like that – because the different kinds of objects are less important for Iain than the deeper natural forces that all objects stem from.

Now, on to Meillassoux. There are so many things to admire about Meillassoux's book. Stylistically, it's very clear and economical. You never feel that he's wasting your time. Something Ray said over coffee either last night or this morning is that analytic philosophers would be shocked if they read this. They would say 'This isn't the French philosophy we heard about', because he's actually making rational arguments, step by step deductive arguments, which analytic philosophers pride themselves on doing, as opposed to those from the continental tradition. At first the argument about causation using the Cantorian transfinite was less convincing to me than the others in the book. But I've been thinking about this more for the past few weeks, and it's growing on me. So are there other ways to use the transfinite to solve other problems like this, such as the bogeyman of the infinite regress? Could you talk about a transfinite regress instead? I'm not sure how you would do that, but I've been toying with these ideas. You can certainly do it in the other direction: the universe is getting bigger and bigger and bigger. However big the universe is defined there must be a bigger universe, and physics seems inclined to support this lately.

Disagreements? The main disagreement here is obvious as well, which is: causation is the key for me, and for Meillassoux causation disappears. In some ways he leads us to a more chaotic universe than Hume does, because as Meillassoux himself says, Hume really doubts whether I can *know* that there's a causal relationship between things, whereas Meillassoux *knows* that it's absolutely contingent, the way things happen. He absolutely *knows* that there's no causal necessity between things. And that might be a brand new gesture. I don't know anyone else who has done this. He's doubting the Principle of Sufficient Reason while keeping the concept of non-contradiction, and he's thereby doubting necessity. But he actually goes further than this, and he doesn't talk about this much explicitly, but in my view, since he is saying that everything is *absolutely* contingent, what he's really doubting is that there's any relationality at all. Everything's absolutely cut off from everything else, because if one thing could be connected to another or could influence another thing, then he wouldn't have absolute contingency anymore. He would sometimes have relations between things and sometimes not. So it seems to me that absolute contingency entails no relations at all between anything, and this is why I have called Meillassoux a hyper-occasionalist, because he doesn't even have a God to save us from this problem. And unlike Hume, he does believe there's an ancestral world outside of us that exists, and it's totally outside of our minds, and we seem to have no access to that either, because that would require a relationship between me and what's outside of me, and that also seems impossible. So maybe I can know *a priori* that there's an ancestral world, and I may also have these qualities in my mind that are somehow linked in my mind, but – according to my reading of his system – there's really no hope of linking these things. It seems to me that in his system nothing touches anything else at all, not even partially, so in that way we're very close in our positions. The difference is that I try to find some solution so things can relate through the back door somehow, and he doesn't do this. And this leads to several other related problems.

So my first question to Meillassoux is: Does a thing touch its own qualities? He may disagree with my assessment that he's saying that nothing relates to anything else or touches anything else, but if he accepts that reading of his system, the question will come up as to whether a thing can even touch its own qualities. What is the relation of a thing to its own qualities? Within the mind, things do seem to relate, because there are many things in my mind at once, so there already is a kind of relationship. This is the criticism I made of Hume – you're starting with a relation. I see different splotches and colours and shapes around the room, and they are somehow related, because they're all in my mind at once. Also, if it's true, then there would be no relation between my perception of the world and the world itself. So that even if we know through his brilliant argument at the beginning of the book that there must be an ancestral realm outside of knowledge, what's the bridge between those two? How does my knowledge have any correspondence at all with what's out there? Correspondence seems impossible and so does unveiling, on Meillassoux's model. How does my mind relate to the world? And finally, what are the things outside the mind? Because if it's true that there's a problem, for Meillassoux, of linking a thing to its qualities, this means you have nothing but disconnected qualities outside the mind. And that doesn't make any sense to me, because, as I mentioned earlier about Merleau-Ponty, the black is already impregnated with the thing of which it is the blackness. So there are already these bridges in perception, and I would say, then, in causation as well. So, my question or objection to Meillassoux – and again, he might disagree with this reading completely – is that he's dealing only with necessity and contingency. Isn't there a middle ground, and isn't that middle ground a relation or interface? Because when two things relate, when you talk about a relationship, well, that's not absolute contingency, because they are affecting each other, right? And necessity implies almost a lack of separation between them, since it implies a kind of seamless mechanical whole in which an action already contains its effects. What a relation really consists of is two things that are somehow partly autonomous yet still manage to influence each other. And so my question is: Is there any possibility of interface in Meillassoux's system? Can one thing influence another without there being a necessary relationship between them? And finally, my real objection to him is that he hasn't published his system yet, because I'd love to stay up the next three nights and read it! That would be great reading. He says he's got multiple volumes coming, six or seven hundred pages. I would be delighted to read this right now, so please hurry! Alright, now I'll listen to the responses from my fellow panelists.

*

Ray Brassier: I take your point absolutely about the unfeasibility of reductionism. I think you're right. There are two problems: inter-theoretic reduction is often intractable, but even intra-theoretic reduction, even within a single theory there are often intractable problems associated with trying to reduce something to something else. So in a way I think that's right, and it's my own fault for over-emphasising this, over-egging the pudding, in my objections to a straightforward ontological univocity. But I do think we can revise the criteria in terms of which we ascribe reality to something. So, I would favour the term 'revisionary materialism' – which, before the term 'eliminative materialism' was canonised, was a plausible variant. In other words, the point is that you're not throwing something out, you're replacing something and amplifying and augmenting what you know and what you understand. This is the important thing. So, for instance, the elimination of gods, goddesses, all sorts of supernatural aspects – that can be understood as a diminishment of the world, but surely that would be kind of a parochial perspective! It's the amplification, it's all the other things we know about that's important. The point is that science has *multiplied* the kinds of things that exist in the world, it hasn't *diminished* them. So it seems to me to be a mistake to think that science and the amplification of our cognitive capacities is about having to give lots of things up and having to eliminate things. Sure, we eliminate things, but only in order to re-describe them as vastly more interesting and complicated things.

The second thing is, I think you're also right that it's unfeasible to claim that there's some kind of ultimate ontological substrate underlying appearances. This is the reason why I think materialism is highly problematic and, as Iain pointed out, it seems to dissolve into some form of alibi, a claim about the primacy of practice or suchlike. Because once physics has eliminated any kind of substantial understanding of materiality – and the whole point about the critique of metaphysics is the destitution of substance, of the idea that substance is the ultimate stuff of the world – materialism doesn't make any sense unless you adopt a materialism of process, of pure productivity, which I accept is entirely viable. In which case I think the problem then becomes one of convincingly explaining the interruptions or discontinuities in the process.

So I would say that there's no limit to realism. It's crucial not to have a parochial definition of realism in terms of available semantic or cognitive categories, because we will invariably end up revising or even abandoning them. The reason why I think epistemology is important is because of history, and because it's impossible to fix a moment in time and say now we really know everything there is. There's always a kind of dynamic and a revisability about the way in which we understand the world. And what's interesting about science is just how much it enriches the categories and the criteria we have for making differences in the world. So it's not a diminishment at all, it's a fantastic enrichment and amplification of our discriminatory capacities. We can make all sorts of differences that it was impossible to make previously. So that's my response, basically.

GH: You defended reductionism less than I thought you would. One of the things I like about talking with you is always the way you force me to think about this problem, because it is a problem. In a sense, it's hypocritical to say that nothing can be reduced to anything else, because what does philosophy do? Philosophy takes a very complicated world and reduces it to four or five structures that explain everything else. I guess all the sciences do this as well. Your point about how science has complicated things is also a Latourian point. He sees modernism as hypocritical. At the same time that it's trying to purify the natural from the cultural, it's also creating a multitude of Frankenstein-like hybrids that are crossing over the gap. The ozone hole is both natural and socially-constructed and narrated at the same time. So things only get more and more complicated. How much reduction actually happens? Often when we 'reduce' we are really just explaining things in terms of a new sort of belief. Chemistry is more complicated in the Periodic Table than it was before, in a sense. They weren't just reducing, were they? Although Mendelev did reduce chemicals to a small number of elements via the Periodic Table, he also pointed to a host of new elements and chemical properties that had not been suspected before. I think that's all I have to say, but I'm sympathetic to the idea that reductionism should not just be thrown out. We have to be able to do a better job of showing how the tooth fairy is less real than a forest.

Quentin Meillassoux: I would like to say to Graham that there can't be any contradiction between our positions, and I will try to show why. I try to elaborate a principle, the principle of factuality, which says that only contingency is necessary. Not merely that contingency is necessary, but that *only* contingency is necessary. So, what do I try to do? I try to demonstrate that contingency has properties, fixed properties. And why do I have to demonstrate it? Because contingency is necessary, and a discourse about something necessary must be a demonstration. And if contingency and only contingency is necessary, everything which exists is contingent. So, I can't speak about what exists. I can't speak about what exists, because it is contingent. Now, what can you do with that which is contingent? You can describe it. What I try to demonstrate is that if you want to speak about what exists you can only *describe*, as phenomenology does – phenomenology is a description. If you want to know where I am, where my system is, in relation to your thinking, the connection lies in the fact that you describe things. It is necessary that phenomenology must be description, because, unlike what I do, phenomenology speaks about things which effectively exist. And what I try to do is to show that if you can describe it, it's not for a contingent reason. It's because what exists is just *a fact*. It's a fact that there is relation, that there are really substances, *etc*. And if you want to know how my work relates to what you describe, I would say, maybe it concerns the 'withdrawing substance', because what withdraws from description, for me, is the *fact* that it is. The fact that the thing *is* cannot be described. You can describe *what* it is, *how* it is, relation, *etc*., but that relation, substance, *etc*., are facts, and because they are facts you can only describe them. In my language, this is 'ontical' description. Ontical – concerned with what there is. But the *ontological* is concerned with demonstration. The discourse of being is, for me, demonstration, because for me, to be is to be a fact. Why do I say that? Because when you try to speak about being, you have this problem: for me, Heidegger doesn't speak about being. He speaks about modalities of being – conscience, Dasein, *etc*. That there is something, of course, he speaks of it, but it is very difficult to see if he really manages to produce a discourse about it. For me, if you want to have a discourse, an extended discourse, about this very narrow fact that there is something, you must remark that for something to be means the *fact* that it is. The fact, it clearly means to be, and I just speak about this invisible property, this invisible reality of things. Because animals, etc., don't see factuality, we don't see factuality. We *think* it. So you speak about what there is, whereas I speak about this, that it is a fact. There could be another world than ours. So my conception is not to deny the existence of relations but just to affirm their factual existence.

GH: Okay, but the relation between anything I see and what it might be representing? There doesn't seem to be any such relation for you, because what's withdrawing is the factuality rather than the subterranean being of the table, or something like this.

QM: It is not a necessary relation, but it is a relation. I say that laws exist. There are laws. For example, if I'm a Newtonian, I can say there are gravitational laws. I don't deny the existence of laws. I don't deny the stability of laws. Maybe these laws will persist for eternity, I don't know. I just say that it is *possible*, really possible, that laws just stop working, that laws disappear. They are facts, just facts, they are not necessary. It's not that you say that if something is contingent, you say that that it doesn't exist. It's factual, that's all. I fully uphold your right to be a phenomenologist, if you want to speak about things, because you have to describe them.

GH: Right. This is very helpful. I'm seeing your work differently now. There are relations, they are the relations of something contingent. Yes, that makes a lot of sense.

QM: What is strange in my philosophy is that it's an ontology that never speaks about what is but only about what can be. Never about what there is, because this I have no right to speak about.

GH: Wonderful. I need to think a little more. Maybe I was reading too much into this by interpreting that there were no relations between anything at all in your philosophy.

IHG: Actually, that is fascinating, and I think I accept completely the idea that contingency is fact. We can't gainsay that, because if we do we claim access to some positional element of necessity. But I don't think, actually, that it applies wholly to the position that you're [GH] adopting. You want egress from phenomenological treatment to a genuine description of causality, as you were saying, or a genuine account of causality. And you do that not because you don't want merely to *speak* about being. You reformulate the ontological difference, as it were, not in terms of being and beings but … sorry, how did you put it?

GH: In terms of the subterranean thing and its relation to something else.

IHG: Yeah, in terms of relations. So you really want to speak about causality. Causality must of its nature be responsible for facts, but is it itself a fact? If there is real causality rather than just the laws we might subscribe to concerning causality, then it entails that there's an egress from the phenomenal envelope, the transcendental envelope, if and only if there is such causality. So there are, as it were, ontological commitments or entailments of your position, it seems to me, and so it's not wholly describable in terms of fact. Unless, of course, we have a specifically temporal understanding of facticity, such that factual states, ontic states, do appear and disappear with roughly the speed that they would under the model you explicitly evoked vis-à-vis Arab scholars' versions of occasionalism, where the raw speed of possible replacements, states of affairs, becomes bafflingly unthinkable.

So that was a comment I just wanted to make to pull things together. I do think there's an interesting question there, or a series of questions, actually. Vis-à-vis what you said about bodies, I have a roughly similar point. It's true I do suggest that it's wrong to identify matter with bodies but not that bodies are immaterial. So, at one level, the reason why it must be wrong to identify matter with bodies is that if it were the case that matter was a body, then all different bodies would not be matter, which wouldn't make sense of what a body is. So it must be the case that bodies are matter, but bodies are not all there is to matter, and I think that's roughly, actually, one of the central lessons of the advent of field physics. The dereliction of substance in any corporealist form is made real, is made concrete, with Faraday and so on – the idea of field replacing substance around the 1830s. So you have this replacement of a conception of substance as no longer attaching solely to bodies, but rather being a regional element of *physis*, which is comprised of forces. The question then is not reducing bodies to forces, nor saying bodies are other than matter because forces are genuine matter, but rather how these two elements are in fact elements of a process which is productive. Actually it was incredibly poignant when you said I don't go to geology – I would have, had the time not run out! You pointed out that I hadn't in fact dealt with certain things in the examples I gave of my project – technological objects and geology as a science, actually dealing with the earth and so on. But in fact that's the subject of my next book on ground. So I wanted to suggest a clarification of the relationship between body and *physis*, body and matter – which is why I think Plato's idealist account of what matter is is the best we have in so far as it's an account of matter …

GH: You also mentioned Giordano Bruno as an obvious ally of yours.

IHG: Yes.

GH: I immediately thought of his books when I read yours. But am I not right that, for you, *physis* does not exist in the bodies, except maybe as *expressed* in the bodies – but the action is all at the lower level?

IHG: I don't think one element of it is dispensable. I think maybe there's some work I need to do here, because I think this is a similar question to the question of the relation between productivity and product. Clearly, the relation as I described it earlier, that productivity is unthinkable without product is a dialectical trick at one level. But at another level, productivity really is productivity if and only if there are products. Otherwise, what is it? Is it force? Is there force without resistance?

GH: For you, when fire burns cotton, what's happening? Is the fire burning the cotton or is there some deeper layer at which the causal relationship is unfolding? I thought the latter.

IHG: I'd want to claim that there are innumerable things going on when fire burns cotton, and in the burning of the cotton by the fire.

GH: But it's not a somatic event for you?

IHG: It's a somatic event, a somatic event is one dimension of it, yes.

GH: So you're not actually denying causal relations between bodies, you're just saying that it's paralleled by another relationship at another level?

IHG: Actually, no, I think I *am* denying causal relationships, but only because it's between bodies. And this is not to say that there are no causal relations. It's rather that they go in a variety of directions. If there are causal relationships between bodies – in fact, there must be at one level, there must be, but at another level, it's not by virtue of the bodies that there are causal relationships between them, because there are other things going on as well. So it's the additional element rather than the one or the other. In fact, that was one of the things about your account of occasionalism that I found so useful.

GH: Good, good.

Benjamin Noys: Earlier you made the remark dismissing Marxian materialism as impoverishing. And I just wondered, in relation to the conversation you had with Ray, there seems to be a question of different kinds of reduction …

GH: My idea, which I had vaguely in mind until Bruno Latour said it explicitly about a month ago, is that materialism is a kind of idealism. And that's what I want to say, because when you have materialism, what you're doing is reducing the things of the world to a fairly one-dimensional conception of what they are. Physical bodies taking up space in a measurable fashion. And the funny thing is, Žižek does this and *embraces* it and says the only possible materialism is idealism. The irreality of the world outside of my experience of it. So he actually takes that and celebrates it and Latour condemns it from the other direction. I want to condemn it, too. So I was happy with Iain's answer. I'm an anti-materialist.

Alberto Toscano: I'd like to just follow up on Ben's point. I was wondering if there was another way of organising your index cards, and it has to do exactly with whether the notion of realism should be understood in terms of – this might be a bit abstruse – but in terms of a reference to the real or a reference to reality. It seems to me that if realism has a reference to 'reality', then there is an implicit totalisation of that notion of reality. And I was struck, for instance, by the fact that, in your talk, in a way that didn't really seem to be thematised, you talked about 'the world', and Iain to some extent or another talked about 'nature'. And

I suppose the question is: Is it necessary for speculative realism to totalise reality, or to posit a grand total object of speculation? There are a number of reasons for asking this. I mean, partly, it's out of the notion that if indeed someone like Ray, for instance, or perhaps Quentin, has an attachment to certain aspects of Badiou's ontology, one of those aspects would be a fairly radical gesture of de-totalisation, the idea that the very notion of a universe might be scientifically useful but is philosophically incoherent, the notion of the All. And it also links partly to the question about politics and Marx and so on, because, in one sense, it only becomes a kind of suppressive gesture to politicise ontology or to talk about politics at all if you think that there is actually a total domain of reality or being; because then obviously if this total domain were overdetermined by one aspect of that domain, then this would be some kind of instrumentalisation of ontology. Because that implies the idea that what speculative realism relates to is *all* of reality, and then obviously if politics comes to overdetermine that entire reality, then that would be illegitimate. Now, if there is no total reality or total universe over which ontology or anything, speculative realism, operates, then it seems there's no sense in which one would need to have a speculative realism or an ontology that encompasses science, *etc.* This also has to do with the question Ray raised, because it's also the issue about the extent to which the demands of science and the demands of ontology overlap. Because it does seem that science is wedded to some extent or another to the notion of a universe. Now, it seems to me that speculative realism need not be – in fact, perhaps *shouldn't* be – wedded to the notion of a totality or of *a* reality or of *a* universe.

So when you said 'the world', does a philosophy of objects, of absolutely individuated, vacuum-packed objects, so to speak, as you put forward – does it depend on some totalisation? Because then that would imply that that totalisation is actually the relation within which all those objects are already included.

GH: Ray and I were discussing this on the Tube on the way in. It seems that I have to be committed to the notion of an infinite regress and also infinite progress to avoid this problem of totalisation. And I do feel that I'm committed to that, and I think science is leading that way more and more all the time, right? Where is the smallest particle? They've never found it. Where is this largest universe? Many physicists doubt it now. And I've been speaking openly in the past few years in defence of the infinite regress and the infinite progress. Maybe I should start calling them transfinite. So, no, I don't actually have a totality of the world. There are just objects as far as you look. I never come to the end of them and say there's a largest object that contains them all, precisely for the reason you mention, because then you'd have a final, present-at-hand – in the Heideggerian sense – present-at-hand totality which was constituted totally of relations and which itself was nothing but relations. And I can't have that, for the same reason that I can't have a smallest particle, because then you'd have a tiniest present-at-hand atom that had no other qualities, because it would have no relational structure at all. So yeah I do seem to be committed, and this upset me a little bit for the first couple of years …! No-one wants to be trapped in the infinite regress, right?

Well, what's inherently illogical about the infinite regress? There seem to be a fewer negative consequences than there are to saying there's got to be a final atom.

Daniel Miller: I want to ask you a bit more about infinity, with reference to your notion that the object has infinite qualities. You spoke of the chair, earlier, as having infinite qualities. There seems to be a problem, because, again, earlier still, you spoke about what the difference would be between a real crown and an imaginary crown, and you suggested that they could be distinguished on the basis of their qualities. The real crown would have different qualities to the imaginary crown. But if an object has an infinite amount of qualities, how can you distinguish it on the basis of those qualities?

GH: Just by appealing to Cantor, that there would be different sizes of infinities. You could say the imaginary crowns have an infinite number of qualities and the real crowns may have more or less qualities than the imaginary ones, but you can still have different sizes of infinities.

DM: Do you make a distinction very cleanly, between imaginary and real infinities, in that case?

GH: No, there's only one kind of infinity. They'd be different infinities in each case but only one kind. What I'm trying to say is, I don't think you can distinguish between imaginary and real crowns on any basis outside of qualities, because the distinction has to be in those qualities themselves. My suspicion is that there have to be different qualities in the cases of the real crowns and the imaginary ones. Existence is not something either imposed or not imposed on the qualities from outside, by God, or by its position in relation to a Kantian subject. In the qualities themselves there has to be a difference between real and imaginary crowns – that's just my suspicion in the last couple of months.

Peter Hallward: Without trying to ask questions I've asked before, I understand your system as far as it works for intentional objects: a chair is not exhausted by your sitting in it, but nevertheless it is a chair as opposed to a hybrid of materials or a commodity or something else, in so far as it can be sat on and have all the other associations that make it a chair and not another kind of object; and it's slightly different, then, from a pile of rocks that we can sit on outside – that alone doesn't make it a chair, right? And we've used it as a chair already today. So as regards the issue of its 'chairness' it seems to me that you have this problem of what it means for this particular object, what it is that objectifies it as a chair or as a table if it's not something to do with a very large number of relationships in that very complicated history of the evolution of something like a chair in the course of history and so on that would explain it. And if you abstract from all those relationships, I don't see what's left of the chair *qua* chair. I can see that you can abstract something. You can probably abstract something that starts to look a lot like a Kantian thing-in-itself, but how would it be a chair? Or if you take something that's less obviously an intentional object, like a cloud or something, and you try, in a rigorous way, to isolate the product from the process, you abstract it, then, from all the processes whereby water vapour condenses at a certain temperature and altitude and so on, what are you left with? In what sense is it really a cloud as opposed to a particular moment that we can isolate in the way precipitation is condensing up there in the sky? In what sense is it a cloud except for someone who *intends* it as a cloud?

GH: Right. You made a very similar objection to 'On Vicarious Causation' before it was a *Collapse* article, which is when I was using shoes as an example, and saying the shoes are the same shoes for me and other people and for ants, and you were asking: Is it really a shoe for ants? And I guess now that I've thought about it for a few months, I think the answer is no, obviously, it's not really a shoe for ants, it's something else, but that doesn't mean there's nothing withdrawing behind my use of it as a shoe. DeLanda makes this point very well on the first page of his new book, which is that, even though we are the ones that create social institutions, this does not mean that our concepts of them exhaust them. So yes, I can be the first person ever to see that pile of rocks as a chair, but couldn't there still be a 'chairness' to it deeper than my use of it? Because I could still keep using it as a chair and still find some leeway to use it as a chair differently from how I'm doing it now. So I think that 'chair-form' that I myself have discovered there is still something deeper than my current use of that 'chair-form'. That's how I would describe it. I don't know if that helps.

Robin Mackay: This very much follows on from Peter's question. I'm very sympathetic to the idea that we have to try to break reality out from its incarceration in our relation to it, our conditioning of it, but it seems to me that physics already does that, but it does it precisely at the expense of the commonsense idea of what an object is. And what puzzles me about your system is that you seem to carry over that commonsense idea of what objects are into this other realm. So, for instance, if there's a billiard ball that hits another billiard ball and it envelopes that other billiard ball in its intentionality – first of all, I can't understand, this is not really an important point, but I can't understand why the intentionality is an object; what is it that makes you call it an object? But secondly, what part of the second billiard ball does the first billiard ball envelop? Only the bit that it hits? The whole thing? How does it know the billiard ball's an object? Does it only envelop half of it, quarter of it? And it seems to me the only way you can answer that is by saying every single piece of the billiard ball envelops every other piece in contact with it, with its intentionality. And so you go down and down, and you're just going to end up with physics again, you're just going to end up with the same ontic explanation of causality that disappointed you in the first place. So, just to go back to Peter's point, it's entirely possible that the ant doesn't know the difference between the shoe and the table that the shoe's on or the piece of grass it's on; I don't understand how these things can be unequivocally named 'objects', in other words, and for me this is the profundity of Lovecraft, why he's a profound realist. Because when you go through the gates, when reality is revealed to you, it's just this complete chaos which you can't objectify. And obviously Lovecraft is Kantian in that respect, but I can't see how your system can get past that problem.

GH: There are three questions there and I'll take the easiest one first: Why is an intention an object? Well, if you look at the usual definitions of objects throughout the history of philosophy, criteria are along the lines of naturalness, indestructibility, irreducibility to anything else, and so on – these are the classical definitions of substance. My definition of an object is simply a unified thing that has a reality that's not exhausted by any approach to it from the outside, and intention clearly has that feature, because what is phenomenology about? It's about retroactively analysing intentions. Even if I analyse what my intention is at the moment, what looks and what is looked at are not the same thing. So what I'm doing when I'm looking at my own intention of the cup is converting my relation to the cup into an object. It can remain mysterious and puzzling and they do long phenomenological analyses, even of these very simple relations. So that's why it's an object.

RM: But when you say you're converting your intention into an object, that's a very Kantian thing to say, isn't it?

GH: I think anytime we intend something, the intention can be converted into an object, yes. But, just as DeLanda says about social institutions: even if we're creating it, that doesn't mean that our creation of it exhausts the reality of the thing. So, yes, in a way my relation to the cup isn't really an object until I convert it into one as a phenomenologist. I can decide, 'Okay, I'm going to analyse my relationship to this', but that doesn't mean that my act of identifying the relation for the first time exhausts it. That's why you have to go on and analyse that intentionality there, because there's more in it than meets the eye. Just by creating kids, you don't know everything about the kids. There's always going to be more to them than you suspected. Causation is productive. I don't think you can ever get from my position to physics, because physics never makes causation into a problem, as far as I can see. The problem of causation in physics is always one of whether causation is deterministic, or whether it's statistical, or how you read quantum theory. There's not really any discussion in physics of what actually happens when one thing influences another.

RM: Isn't that because physics has revealed that that's a false problem?

GH: I don't think it's a false problem. I think it's a *forgotten* problem, by physics. You've got four causes in Aristotle. Where have the four causes gone in physics? Nowhere. You have efficient causation, maybe material causation, they've gotten rid of formal and final. Fine, get rid of final, I'll give you that one! – What about formal causation? Formal causation is where all the action's happening in philosophy, I think. Forms do all the work in Aristotle and elsewhere, and that's what I want to retain. There's no formal causation in physics. My favourite author for dealing with formal causation is Marshall McLuhan, one of the really unrecognised giants of the past one hundred years of the humanities. Fabulous stuff, wrongly written off as a kind of pop TV analyst, really brilliant systematic work about how one medium reverses into another under the right conditions. McCluhan deserves to be the founder of a philosophical school. Again, he's a fan of formal cause. And Francis Bacon before him – another completely misunderstood philosopher – not an empiricist in the way people think. You're not just doing experiments and reducing things to their causes, you're actually finding the forms that are locked up and compressed inside of things. And he even says that efficient causation is ludicrous. I was shocked when I read that. We have this textbook image of Bacon that has nothing to do with the real Bacon. So I would appeal to Bacon and McLuhan, great champions of formal cause, which science does not handle properly.

Presentation by Quentin Meillassoux

I would first of all like to give my thanks to the organisers of this conference. I'm very proud to participate in it, considering the exceptional quality of the contributors. And I am very happy to have this opportunity to express my admiration for the books of Ray Brassier, Graham Harman, and Iain Grant. I think that the very existence of such a philosophical configuration of original conceptual projects is in itself remarkable. I think that we also must have in common, the four speakers, the difficulty of explaining our jobs to our families! But as I said to Graham, I think it is a configuration of what could be called a 'weird realism', four modalities of 'weird realism'. I'd like to discuss here one of the theses of Ray Brassier's beautiful book, *Nihil Unbound*, and try to respond to some of his stimulating objections, supported by the non-philosophy of François Laruelle. Thanks to this discussion, I will expose and mark out the fundamental decisions of *After Finitude*, especially concerning correlationism and the principle of factuality.

As you may know, I have given the name 'correlationism' to the contemporary opponent of any realism. By this term, I wanted to avoid the usual 'parade' of transcendental philosophy and phenomenology against the accusation of idealism – I mean answers such as: 'Kantian criticism is not a subjective idealism since there is a refutation of idealism in the *Critique of Pure Reason*'; or 'phenomenology is not a dogmatic idealism, since intentionality is orientated towards a radical exteriority, and it is not a solipsism since the givenness of the object implies, according to Husserl, the reference to an intersubjective community'. And the same could be said about *Dasein*, which is originarily a 'being-in-the world'. Even though these positions claim not to be subjective idealism, they can't deny, without self-refutation, that the exteriority they elaborate is essentially relative: relative to a consciousness, a language, a *Dasein*, etc. No object, no being, no event, or law which is not always-already correlated to a point of view, to a subjective access – this is the thesis of any correlationism.

By the term 'correlation', I also wanted to exhibit the essential argument of these 'philosophies of access', as Harman calls them; and – I insist on this point – the exceptional *strength* of this argumentation, apparently and desperately implacable. Correlationism rests on an argument as simple as it is powerful, and which can be formulated in the following way: No X without givenness of X, and no theory about X without a positing of X. If you speak about something, you speak about something that is given to you, and posited by you. Consequently, the sentence: 'X is', means: 'X is the correlate of thinking' in a Cartesian sense. That is: X is the correlate of an affection, or a perception, or a conception, or of any subjective act. To be is to be a correlate, a term of a correlation. And in particular, when you claim to think any X, you must posit this X, which cannot then be separated from this special act of positing, of conception. That is why it is impossible to conceive an absolute X, *i.e.,* an X which would be essentially separate from a subject. We can't know what the reality of the object in itself is because we can't distinguish between properties which are supposed to belong to the object and properties belonging to the subjective access to the object.

In my opinion, the *Principles of the Science of Knowledge*, written by Fichte in 1794, is the *chef-d'oeuvre* of such a correlationism. The *Science of Knowledge* is to date the most rigourous expression of the correlationist challenge opposed to any realism. I'd like to begin this talk by remembering the principal aspect of this philosophy, so that we can be conscious of the very nature of this anti-realism at its climax. I won't speak, of course, about the details of this very difficult book, but I shall only recall the heart of its argumentation: the principle of its conceptual production, which appears to me as the most precise form of the obstacle that a contemporary realism has to surmount. I will rely on a recent interpretation of the *Science of Knowledge*, which has completely changed the comprehension of Fichte, at least in France: in 2000 Isabelle Thomas-Fogiel[14] proposed a devastating criticism of the dominant interpretation of Fichte in our country – Philonenko's interpretation – and allowed us at last to read the true *Science of Knowledge*, instead of the extraordinary but also eccentric reconstruction elaborated by Philonenko in 1966.[15]

Briefly: Philonenko claimed that the three first principles of the *Science of Knowledge* – including the famous 'I = I' – were not true principles, but dialectical illusions that Fichte undertook to deconstruct throughout his system. So, in the *Science of Knowledge*, you have three principles, and he deduces all that follows from these three principles? – No, it's not true! According to Philonenko, they were illusions that Fichte deconstructed! Therefore, of course, Philonenko also had to explain that Fichte was a strange guy, since he had said to everyone the exact opposite of what he really meant! The situation in France was as if a famous interpreter had claimed solidly for thirty years that the definitions and axioms of Spinoza's *Ethics* were in fact certain illusions deconstructed by Spinoza, and convinced everybody that Spinoza was just a very weird man to say systematically the exact contrary of what he really thought. Thomas-Fogiel quite simply restores – in my view, indisputably – the immediate truth on this point: the principles of the *Science of Knowledge* are *true* principles; and, thanks to her, French philosophers have at last discovered what everyone else already knew!

[15] A. Philonenko, *La liberté humaine dans la philosophie de Fichte* (Paris: Vrin, 1966).

How must we read Fichte, consequently? According to Thomas-Fogiel, as a thinker of the pragmatic contradiction: Fichte is a thinker who intends to evaluate every philosopher by his capacity to do what he says and to say what he does. A pragmatic contradiction consists, as you know, in contradicting the content of a sentence by the enunciation of this very sentence. It is not a logical contradiction – such as: 'Peter thinks and Peter does not think' – but a contradiction between the content of a sentence and its performance, its effective formulation. For example: 'I don't think' does not contain a logical contradiction, but consists in a pragmatic contradiction between the content of the proposition and the fact that I think or pronounce it. The fact that I think this proposition is in contradiction with what I say in the proposition. Thomas-Fogiel used this notion, elaborated by Hintikka in relation to Descartes and Austin,[16] to interpret the *Science of Knowledge* as a philosophy written under the systematic constraint of pragmatic non-contradiction. In particular, the *Science of Knowledge* destroys any attempt at realism by proving it is always and immediately self-contradictory in a pragmatic way. What is a philosopher really doing when he claims to have access to a reality independent of the I? He posits, says Fichte, an X supposed to be independent of any position. In other words, he posits the X as non-posited. He pretends to think what is independent and exterior to any conceptualisation, but in doing so he doesn't say what he effectively does. He says his X is indifferent to thought, but what he does, of course, is simply to conceptualise an X perfectly dependent on his own thinking. Hence, according to Fichte, the pragmatic contradiction between the acts and the thesis of any realist.

---

[16] J. Hintikka, '*Cogito, ergo sum*: Inference or Performance?', *Philosophical Review,* Volume 71, No. 1, Jan. 1962: 3-32, included in *Knowledge and the*

But Fichte's very originality, in which he anticipates Hegelian dialectics, is that his contradiction is essentially fruitful. Contradictions produced – notably, by realism – in the *Science of Knowledge* do not lead to the end of the discourse, but to the creation of new concepts able to temporarily neutralise the mortal opposition between content and act. Only temporarily, since such concepts allow one to shift the contradiction again and again but not to abolish it – at least in the sphere of theory, the resolution of the initial contradiction being the privilege of practical reason, not of theoretical reason.

To be more precise, we could say that there is for Fichte a sort of 'double bind' for philosophy itself: it has both to posit the secondariness of thinking relative to

---

Known (Dordrecht: Reidel, 1974); '*Cogito, ergo sum* as an Inference and a Performance', *Philosophical Review*, Volume 72, No. 4, Oct. 1963: 487-96.

an independent real – otherwise we couldn't explain the passivity of sensation – and at the same time it can't posit such a reality without contradiction. This 'double bind', which is ultimately still what 'realism' means for contemporary philosophy – we need it, but we can't claim it, so we claim *and* deny it – this double bind never oversteps, according to Fichte, the limits of the I, because the active I is the first and absolute principle of his philosophy. But Fichte carries out the most elaborate destruction of any realism through a strategy we could call the 'pragmatico-genetic contradiction'; that is, an exhibition of the way in which the realist is forced to create his own concepts in order to escape, for a while, his ultimately fatal contradiction.

To be a contemporary realist means, in my view, to efficiently challenge the Fichtean fatality of pragmatic contradiction; not exactly to challenge the very thesis of the *Science of Knowledge*, but the mode of refutation which is therein invented, and whose principle is always the same: If you think *X*, then you *think* X. That is what I called the 'circle of correlation', the first argument of every correlationism which claims that realism is necessarily a vicious circle, a denial of its very act. Can a realism pass the test of pragmatic contradiction? That is the question which has governed my own investigations and which I shall examine in relation to the non-philosophy of François Laruelle, on the one hand, and the principle of factuality I set out in *After Finitude*, on the other. But why this comparison with Laruelle?

In his wonderfully radical book, *Nihil Unbound*, Ray Brassier devotes a chapter to *After Finitude*[17] and another to Laruelle's non-philosophy.[18] Brassier, who is a first-class reader, tries to show that Laruelle's 'transcendental realism' is a more reliable and rigorous way to root out the philosophy of correlationism than that which I propose. Even if Brassier's reading is generally kind towards *After Finitude*, he points out what he sees as some weaknesses in my argument, and particularly the fact that I speak of an intellectual intuition of facticity. In this expression – 'intellectual intuition' – Brassier suspects a possible absolutisation of meaning, and maybe a remnant of speculative idealism that threatens my will to escape from the circle of correlation. I shall try to respond to this objection in the following way: First, I will show why the non-philosophy of Laruelle, despite its admirable rigour, fails, in my view, to efficiently fight the argument of the correlational circle. And I will demonstrate this point by applying to non-philosophy a Fichtean model of refutation – that is, a refutation based on the pragmatico-genetic contradiction. Then, I'll show that what I called 'intellectual intuition' in *After Finitude* – and what I shall now call, more precisely, 'dianoetic intuition' – is able, unlike non-philosophy, to neutralise correlationism, even in its Fichtean version – that is, even at the high point of its rigour.

---

[17] *Nihil Unbound*, Chapter 3; also see **Collapse** Vol. II, 15-54.

The funny thing is that I discovered, after I decided to confront Laruelle with Fichte, that Laruelle himself, in his *Principles of Non-Philosophy*,[19] compared his own reasoning with Fichte's in the *Science of Knowledge*. But Laruelle is a tributary of the outdated commentary of Philonenko; that's why his confrontation is disappointing.

[18] *Nihil Unbound*, Chapter 5.

[19] François Laruelle, *Principes de la non-philosophie* (Paris: PUF, 1996).

Quentin Meillassoux

Let's start with Laruelle's conception of what he calls 'philosophy' – or the 'circle of Decision' – which we could also call the 'circle of objectivity'. Decision – with a big 'D' – is for Laruelle the source of every philosophy in any time. Brassier sums up precisely the meaning of this 'Decision' by recalling the Kantian structure which underlies its conceptualisation. Every philosophy is constituted, according to Laruelle, of three moments: first, an empirical *datum*; second, a *factum* made of *a priori* categories, categories unified by a transcendental (for Kant, transcendental apperception); and finally, we have a return of the *a priori* to the *datum*, that is, a unification of *datum* and *factum*, a moment which, in Kant, corresponds to the transcendental deduction. From this last unification proceeds experience as the transcendent reality produced by philosophy. Those moments we might also call 'circle of philosophical Decision', or 'circle of objectivity'. Brassier contests – and I think he's right to do so – that this triple movement constitutes, for Laruelle, the eternal essence of philosophy. He suggests that what Laruelle calls 'philosophy' can be identified with what I call 'correlationism'. Consequently, Brassier claims that Laruelle, with his non-philosophy, works out a non-correlationism more radical and sure than my own version, burdened as it is by intellectual intuition. Let's see how Laruelle proceeds to extricate himself from the field of philosophy – that is, correlationism, in Brassier's version. I can't of course reproduce all of Laruelle's reasoning, which is complex and evolves from one book to another, but I won't need to do so to explain my objection.

First, I remark that there is a precise reason, different from Brassier's own reason, to refuse the identification of philosophy with the circle of objectivity. Brassier claims it is vain to look for an eternal essence of philosophy, philosophy being constituted by the contingent history of texts. But I think there is another reason, a structural one, to refuse the idea that philosophy should be encapsulated in the circle of objectivity, one that Fichte was probably the first to conceive. This reason is: if you want to think the circle of objectivity – what Fichte calls the representation, the unification of *datum* and *factum* and the *a priori* – you need a point of view outside of this circle. That is, if you want to conceive what a representation is, you need a faculty which can't itself be representative, because there is no representation of representation. You can have a representation – perceptual or imaginative – of a horse or a wall, but you can't have any representation of a representation. If you want to think what a representation is – that is, a unity of *datum* and *a priori* – you need something other than objective knowledge, this being itself constituted by the unity of *datum* and *a priori*. This was Kant's essential failing, according to Fichte: Kant didn't explain how it was possible to write the *Critique of Pure Reason*. He described all knowledge in terms of objectivity – that is, in terms of representation, constituted by the synthesis of categories and space-time – but his own *philosophical* knowledge about objective knowledge, that is, about representation, couldn't be described in the same terms. How was Kant able to elaborate transcendental notions such as matter and form, categories and representation? This operation needed, according to Fichte, another faculty which was almost described by Kant: the faculty of reflection. And this faculty, reflection – contrary to the apparent opinion of Laruelle – is essentially different from objectivity. Reflection is a non-representative, non-objectivating faculty, which is the condition for conceiving objectivity as such. Reflection is what allows Laruelle himself to stand outside the circle of objectivity when he conceives its unity. Laruelle is outside the circle of objectivity when he describes it, because describing it means not being in it anymore. But this is also the case with every philosopher who was able to describe this circle: all of them adopt, consciously or not, the point of view of reflection, but Fichte was the first to consciously and systematically adopt this point of view in order to construct his system.

Consequently, if you want to escape from the circle of correlationism, you must not only escape from the circle of objectivity, but also from the larger circle of reflection, which is outside Laruelle's circle and includes it. Correlationism, as I define it, includes reflection, since reflection is position. When you conceive the circle of objectivity, you are outside this circle, but still in the circle of correlationism, according to me. So if, like Laruelle, you posit something outside the circle of objectivity – in his case the Real outside 'Philosophy' – this Real will still be, according to me, in the circle of correlationism. Because it will be a posited Real: a Real posited by reflection outside of representation. This is exactly what Fichte calls, in his technical vocabulary, the 'independent activity' – that is, to simplify a great deal, the notion of the 'thing in itself', outside representation – Kantian representation – and impossible to conceive through this representation.

Let's demonstrate this point more precisely. Here is my strategy: as I said previously, I propose to apply to Laruelle the Fichtean way of reasoning – not his precise thesis, but the pragmatico-genetic contradiction which constitutes the principle of his argumentation. I am going to reconstruct Laruelle's position in a correlational way, showing how what he calls 'the Real' is nothing but a posited Real, and how the concepts created by non-philosophy just shift this contradiction without being able to abolish it. We shall see clearly, then, why I think that Laruelle doesn't really escape from the circle of correlation.

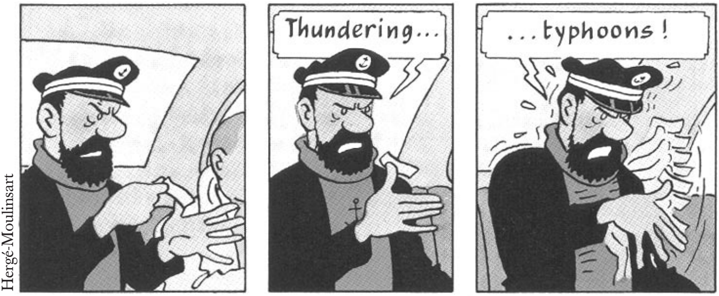
Let's begin with the Real as described by Laruelle. The Real, he says, is radically indifferent to and independent of the circle of objectivity. The Real precedes thought, but thought, conversely, is always dependent upon the Real, which is essentially unaffected by thought. That is what

Laruelle says, this is the content of his discourse. But – Fichtean question – what does he do? What is the act of his discourse? Laruelle, of course, posits such a Real as independent of any thought. Consequently, he does exactly the contrary of what he says. He says, 'the Real precedes thought – in particular, philosophical thought – and is indifferent to it', but the order of what he does is the opposite of the order of what he says: he begins by thinking, and especially by thinking what philosophical thought is, and then progresses to the Real. The Real is truly a notion of the Real which is dependent on thinking, and which is post-philosophical, elaborated from his notion of philosophy. The real order – or the order of acts, not of content – is manifest in the very name of Laruelle's theory: 'non-philosophy'. Non-philosophy is supposed to think the relation of thinking with a Real which precedes philosophy, but the name 'non-philosophy' can only be constructed from the name 'philosophy' together with a negation. Philosophy precedes non-philosophy in nomination, as in the acts of thinking. Hence, we have the first and manifest pragmatic contradiction between what Laruelle says about the Real and what he does when elaborating this notion.

But of course this contradiction, this pragmatic contradiction, is far too trivial to worry Laruelle, and we can imagine that he could easily respond to it. But how? By producing new concepts. So the contradiction, the pragmatic contradiction, becomes fruitful because it compels the thinker to shift it so that he can avoid a gap which in fact will never be filled in. Laruelle could first demonstrate that our objection proceeds from a series of confusions. The Real is a negation of nothing: it is relative to nothing, according to him, and especially can't be identified with the concept of the Other which presupposes the X whose other it is. The Real, on the contrary, is radically autonomous, without relation to thought. Thought, on the other hand, can distinguish itself from the Real if it ceases to identify itself with philosophy, locked up in the circle of objectivity, to think under the axiom of the Real. Then thought knows itself as determined-in-the-last-instance by the Real, says Laruelle. That is: thought knows itself as relatively, but not radically, autonomous. This means that thought can produce by itself its own concepts, but has to avoid the sufficiency of absolute autonomy proper to philosophy and which is its intrinsic illusion.

We now have a series of new concepts: radical and relative autonomy, sufficiency, determination-in-the-last-instance, etc. But have we then escaped from the correlational circle? Of course not; we have only deduced what is necessary to think a *posited* Real, if we admit that this Real effectively precedes any position. But Laruelle gets this first position just by force, just by a *coup de force*. The Real is *posited* as indifferent to its positing and as non-related to thought. After that, Laruelle reflects on the possibility of his own theory by claiming the relative autonomy of thought; but in fact, it seems, on the contrary, that his thought is able to posit the Real itself and its relation to the Real. That is, to posit that the Real has no relation to thought, and that thought has a relation of relative autonomy to the Real. He also posits all these concepts as essentially non-dialectical, but what he does is of course easy to dialecticise. For the Real is now linked more than ever to his concepts, more dependent on more and more intricate elaborations aiming at the exhibition of its independence. And of course, every thesis added by Laruelle will only make the situation worse. That's why the only solution for Laruelle will be the solution, according to me, of every modern realism against correlationism or idealism: as it seems impossible to escape from this position, from this objection, the only solution is to disqualify what you can't refute. The solution for Laruelle can only be: First, to say that the Real is posited by an axiom – that is, something that can be neither demonstrated nor discussed – and secondly, to introduce a precise concept which will disqualify in advance anyone who contests such an axiom; that is, the concept of 'resistance'. I will end my Fichtean reconstruction of Laruelle with this concept that I propose to examine, considering its genealogy and its strategic importance for any contemporary realism.

To understand the fortune of the concept of resistance, we must be conscious of the main characteristic of the correlational circle, which is that this circle is both monotonous and apparently implacable. It is just the same objection, tedious and irritating: if you posit *X*, then you *posit* X. Sometimes we encounter this enraging situation: a brilliant, subtle and interesting theory is easily refuted by a well-known and trivial argument, put forward by a stupid opponent. That is often the situation of the post-Kantian realist faced with the correlationist. And this necessarily produces the same psychological reaction on the part of the realist: he will become both tired and furious. The perfect illustration, the primal scene, of this psychological law of modern realism, in my opinion, can be found in a Tintin comic book. In one of his adventures, Tintin's acolyte Captain Haddock tries to unstick a plaster from his finger.



Thundering...
...typhoons!

Hergé-Moulinsart

But of course, each time he removes it with another finger, the plaster sticks immediately onto it! And since the process is endless, Haddock quickly loses his temper. The plaster is identical to the 'that is what *you think*' that the correlationist just has to add to any realist thesis one might try to assert. The realist always has to posit more concepts to prove he has accessed pre-conceptual reality. The situation seems desperate: how could you refute that whenever you think something, you *think* something? That's why the realist, conscious that his reasoning is apparently in vain, has generally renounced any attempt to refute the correlationist and has adopted what I call a 'logic of secession' towards him. This secession is a blunt refusal addressed to the correlationist: an 'I won't discuss *with* you anymore, I will rather discuss *about* you'. This is a logic of unbinding, of independence, but this independence is not the originary independence of the Real towards the correlation but that of the realist towards the discussion with the correlationist. This logic of secession, it seems to me, takes two principal forms in modernity.

The first one consists in fleeing voluntarily from the discussion in order to rediscover the richness of the concrete world. Schopenhauer said that solipsism was a fortress impossible to penetrate, but also pointless to attack, since it is empty. Solipsism is a philosophy nobody can refute, but also one that nobody can believe. So let's leave the fortress as it is, and let's explore the world in all its vastness! The first strategy of the realist, similarly, concerns the fortress of correlation: 'If you want to stick your plaster on me, please do, but then leave me alone; I have so many interesting realities to investigate!' This is what I call the 'Rhetoric of the Rich Elsewhere'. The realist disqualifies the correlationist argument as uninteresting, producing arid idealities, boring academics, and pathological intellectuals. 'Let's stop discussing, and let's open the windows: let's inhale things and feel the breeze'. This is an attractive and sometimes powerful rhetoric – not in a pejorative but in a Nietzschean sense. A rhetoric of the fruitful concreteness of things, the revenge of descriptions and style on repetitive quibbles. Latour, sometimes, severs all links with correlationism in such a way, and does so with much talent and humour. It must be added, of course, that he also uses other elaborate instruments to fight the circle. But in the case of the 'Rich Elsewhere' rhetoric, it is clear that it is not an argument, but a disqualification of he who argues: the sickly and boring correlationist.

The other method of disqualification used by modern realism is a more fundamental one: it brings out the implicit logic of the 'Rich Elsewhere', which consists in replacing the discussion with the correlationist with an exposition of his motivations. We no longer examine what he says, we examine *why* he says what he says. It is the well-known logic of suspicion that we find in Marx, with the notion of ideology, or in Freud, with precisely the notion of resistance. The realist fights every form of idealism by discovering the hidden reasons behind these discourses – reasons that do not concern the content of philosophies, but the shameful motivations of their supporters: class-interest, libido, *etc.* In this way, the realist explains in advance why his theories must be refused by those who are unable to see the truth for such and such objective reasons. Hence he will neutralise any refutation as an already-described symptom of social or psychological resistance, unconscious resistance which is, according to the realist, often unavoidable. But what is interesting, from my own point of view, is that this well-known strategy of suspicion can be understood as the necessary result of an inability to rationally refute the insipid and implacable argument of the correlationist. And we could say the same about the Nietzschean suspicion of the sickly Kantians of the University. Laruelle inherits these strategies through his own concept of resistance: he says, of course, that his non-philosophy must necessarily excite great resistance from philosophy – he predicts that philosophers will reproach him for a *coup de force*, exactly as I did – and he claims that any refutation he will encounter from the point of view of the circle of Decision is the necessary effect of his theory of the Real upon philosophical sufficiency.

Brassier makes an interesting suggestion regarding Laruelle's theory: he says that one of his major concepts – unilateralisation – is a 'surgical intervention upon the body of transcendental synthesis; severing terms from relations, amputating reciprocity and sharpening one-sidedness'.[20] Unilateralisation is a complex concept in Laruelle that I can't explore now but which is admirably explained by Brassier in his book. It is, generally speaking, the consequence of the thought of the radical autonomy of the Real towards thought. What Brassier says, it seems to me, is that Laruelle introduces into the transcendental circle – constituted by the reciprocal synthesis between categories and intuition – the essential asymmetry of the Real and thought, an asymmetry which disjoins the correlations of critical and idealist philosophies. But my own hypothesis about this power of disjunction is that it proceeds more profoundly from the strategy of secession towards correlationism. The radical autonomy of the Real, its unbinding from thought, is produced by the radical autonomy of the non-philosopher, of Laruelle himself, towards any discussion with the correlationist. Laruelle posits the Real as an axiom, and then he posits his refusal to discuss the correlationist refutation of this axiom with the concept of resistance, which disqualifies any objection without answering to it. It is this very secession with the correlationist which creates in the discourse the effect of the radical autonomy of the Real, and which then produces all the effects of surgical interventions upon transcendental synthesis. The meaning of radical autonomy is Laruelle's secession rather than the severing of the Real.

The concept of resistance is an effect, as we said, of the theory of suspicion. But, in my view, and even if I admire Marx, Nietzsche and Freud, realists should at last start becoming suspicious of this venerable theory of suspicion; Because, as I said, it seems to me that we can trace a genealogy of suspicion and its favourite notion, resistance, which discovers at its root an inability to refute, precisely and simply, the unbearable argument of the circle. I refuse suspicion because realism, in my view, must remain a rationalism. The circle argument *is* an argument and must be treated as such. You don't refuse a mathematical demonstration because the mathematicians are supposed to be sickly or full of frustrated libido, you just refuse what you refute! I clearly understood the calamitous consequences of the notion of resistance when I heard an astrologer, answering placidly to a sceptic, that the latter's incredulity was predictable since he was a Scorpio!

---

[20] *Nihil Unbound*, 147.

What is at stake, consequently, is to build up a realism released from the strategy of suspicion: a realism which doesn't need to *disqualify* the correlationist because it has clearly *refuted* him. I want that easy and implacable refutation to be transferred to the other side, from correlationism to realism; and, conversely, the argument of resistance to become the last possible defence of correlationism itself. But I don't want to refute only to refute and win the discussion. As we shall see, I'm looking for a creative refutation. That is, a refutation which discovers a truth, an absolute truth, inside the circle itself. That's why I propose an access to the Real not grounded on an *axiom*, but on a *demonstrated principle* – the principle of factuality that I'm now going to set out.

The main problem I try to face in *After Finitude* is precisely that of building a materialism – or a realism – able to refute clearly the correlational circle in its simplest form, which is also the form which is the most difficult to fight with: that is, the argument that we never have access to something apart from that access – that the 'in-itself' is unknown since we only know the 'for-us'. Here is my strategy: the weakness of correlationism consists in the duality of its opponents. Correlationism is not, in my definition, an anti-realism but an anti-*absolutism*. Correlationism is the modern way to reject all possible knowledge of an absolute: it is the claim that we are closed up in our representations – whether conscious, linguistic, or historical – with no sure access to an eternal reality independent of our specific point of view. But there are two main forms of the absolute: the realist one, which is a non-thinking reality independent of our access to it, and the idealist one, which is the absolutisation of the correlation itself. Therefore, correlationism must also refute speculative idealism – or any form of vitalism or pan-psychism – if it wants to reject all the modalities of the absolute. But the argument of the circle is useless for this second refutation, because idealism and vitalism consist precisely in claiming that it is the circle itself which is the absolute.

Let's examine briefly the idealist and vitalist arguments. I call 'subjectivist metaphysics' any absolutisation of a determinate human access to the world, and I call 'subjectivist', for brevity, the supporter of any form of subjective metaphysics. Correlation between thought and being has many different forms: the subjectivist claims that some of these relations, or indeed all, are determinations not only of men, but of being itself. He projects into the things themselves a correlation which might be perception, intellection, desire, etc., and makes it the absolute itself. Of course, this process is far more elaborate than I can describe here, especially in Hegel. But the principle of subjectivism is always the same. It consists in refuting realism and correlationism by the following reasoning: Since we cannot conceive a being which would not be constituted by our relation to the world, since we cannot escape from the circle of correlation, the whole of these relations, or an eminent part of this whole, represents the very essence of any reality. According to the subjectivist, it is absurd to suppose, as the correlationist does, that there could be an in-itself different from any human correlation to the world. The subjectivist thus turns the argument of the circle against the correlationist himself: since we can't think any reality independent of human correlations to the world, it means, according to the subjectivist, that the supposition of such a reality existing outside the circle is nonsense. Hence, the absolute is the circle itself, or at least a part of it.

This is why I disagree with Brassier's identification of what I call correlationism with what Laruelle calls 'philosophy'. It seems to me that Laruelle's notion of philosophy as a circle of Decision includes Hegel as well as Kant – idealist speculation with transcendental correlationism. In my view, it is on the contrary essential to distinguish between them since this distinction demonstrates the necessity for correlationism to produce a second argument able to respond to the idealist absolute. This necessity of a second argument is extremely important, since, as we shall see, it will become the flaw of the circle-fortress. This second argument, as I claimed in *After Finitude*, is the argument of facticity, and I must now explain its exact meaning.

I call 'facticity' the lack of reason of any reality; that is, the impossibility of giving an ultimate ground to the existence of any being. We can reach conditional necessity, but never absolute necessity. If definite causes and physical laws are posited, we can claim that a determined effect must follow. But we shall never find a ground to these laws and causes, except eventually other ungrounded causes and laws: there is no ultimate cause, nor ultimate law, that is a cause or a law including the ground of its own existence. But this facticity, this ultimate ungrounding of things, is also proper to thought. The Cartesian *cogito* clearly shows this point: what is necessary in the *cogito* is a conditional necessity: *if* I think, then I must be. But it is not an absolute necessity: it is not necessary *that* I should think. From the inside of the correlation, I have access to my own facticity, and so to the facticity of the world correlated to my subjective access to it. And this because of the lack of an ultimate reason, of a *causa sui*, able to ground my existence.

Facticity so defined is, in my view, the fundamental answer to any absolutisation of the correlation, for if correlation is factual, we can no longer say – as the idealist does – that it is a necessary component of any reality. Of course, an idealist may object that conceiving the non-being of a subjective correlation is a pragmatic contradiction, since the very conception of it proves we exist as a subject – so that we exist, when we speak of non-existence, non-being, we are existing. But we can reply, this time, that we can conceive our facticity even from the inside of the correlational circle, since Fichte himself has proved it. Indeed, Fichte conceived his first principle – I = I, the relation of the I to itself – as essentially ungrounded – in my vocabulary, as essentially factual. Of course, for Fichte, the first principle is not a fact, but an act: the act of conceiving the I. But this act is essentially *free*, according to Fichte – and that means not necessary. We choose whether or not to posit our own subjective reflection, and this choice is not grounded on any necessary cause, since our freedom is radical. But to say this is just to recognise, after Descartes, that our subjectivity cannot reach an absolute necessity but only a conditional one. Even if Fichte speaks abundantly of absolute and unconditional necessity, his necessity is no longer dogmatic and substantial necessity, but a necessity grounded upon a freedom itself ungrounded. There can be no dogmatic proof that the correlation must exist rather than not. Hence this absence of necessity is sufficient to reject the idealist's claim of its absolute necessity.

Correlationism, then, is constituted of two arguments: the circle of correlation against naïve realism – let's use this term for a realism unable to refute the circle; and facticity against speculative idealism, against subjectivism. The idealist, the subjectivist, claims to defeat the correlationist by the absolutisation of the correlation; I believe that we can defeat the correlationist only by the absolutisation of facticity. Let's see why.

The correlationist must claim, against the idealist, that we can conceive the contingency of the correlation, that is: its possible disappearance; for example, with the extinction of humanity. The correlation is contingent: we can conceive the contingency of the correlation. But, in this way, the correlationist must admit that we can positively think of a possibility which is essentially independent of the correlation, since this is precisely the possibility of the non-being of the correlation. We can draw an analogy with death: to think of myself as a mortal, I must admit that death doesn't depend on my own thinking about my death. Otherwise, I would be able to disappear only on one condition: that I was still alive to think of my disappearance and make this event a correlate of my access to it. In other words, I could be dying indefinitely, but I could never pass away, because I would have to exist to make of death a correlate of my own subjective access to it. If facticity can be conceived, if it is a notion that we can effectively conceive – and this must be the case for the correlationist if he wants to *refute* the idealist – then it is a notion we can think as an absolute: the absolute lack of reason of any reality; or, in other words, the effective ability of every determined entity – event, thing, or law of subjectivity – *to appear and disappear* with no reason for its being or non-being. Unreason becomes the attribute of an absolute time able to destroy and create any determined entity – event, thing or law – without any reason for thus creating and destroying.

What I try to show by this thesis concerns the condition of the thinkability of the essential opposition of correlationism: the opposition of the in-itself and the for-us. The thesis of correlationism is that I can't know what the reality would be without me, without us, without thinking, without thought. According to the correlationist, if I remove myself from the world, I can't know the residue. But this reasoning supposes that we have access to an absolute possibility: the possibility that the in-itself could be different from the for-us. And this absolute possibility is grounded in turn on the absolute facticity of the correlation. It is because I can conceive the non-being of the correlation that I can conceive the possibility of an in-itself essentially different from the world as correlated to human subjectivity.

Consequently, I can refute the correlationist refutation of realism, grounded as it is on the accusation of pragmatic contradiction, because *I* discover in correlational reasoning a pragmatic contradiction: the correlationist's fundamental notions – for-us and in-itself – are grounded on an implicit absolutisation: the absolutisation of facticity. Everything can be conceived as contingent, dependent on human tropism – everything except contingency itself. Contingency, and only contingency, is absolutely necessary. Facticity, and only facticity, is not factual, but eternal. Facticity is not a fact, it is not 'one more' fact in the world. I call this necessity of facticity 'factuality'; and the principle which announces factuality, the necessity of facticity, the non-facticity of facticity, I call the 'Principle of Factuality'. Finally, I call *spéculation factuale* speculation which is grounded on the principle of factuality. Through the Principle of Factuality, I can access a speculative realism which clearly refutes, but no longer disqualifies, correlationism. I think an X independent of any thinking, and know it for sure, thanks to the correlationist himself and his fight against the absolute, the idealist absolute. The principle of factuality unveils the ontological truth hidden in the radical skepticism of modern philosophy: to be is to be factual – and *this* is not a fact.

I shall now move on to my last point: intellectual intuition. I used this expression in *After Finitude* to characterise the intellectual access to factuality – that is, the access to facticity as an absolute – and Brassier wrote that such a notion threatens to close me again into the circle of correlation. Intellectual intuition, with its heavy idealist connotation, seems to entail an absolutisation of meaning, hence an absolutisation of thought. It seems to be a dangerous concession made to correlationism. Let's try to respond, to give an answer to this objection.

What did I mean, exactly, by this expression, 'intellectual intuition'? Why did I take the risk of using an idealist expression in order, of course, to subvert its meaning? From now on, I shall use, if you prefer, the oxymoronic term *intuition dianoétique*, 'dianoetic intuition'. I mean by these words, the essential intertwining of a simple intuition and of a discursivity, a demonstration – both being entailed by the access to factuality. Let me explain this point.

Why do I think that Laruelle fails to escape correlationism? It is because he doesn't begin by refuting correlationism but by positing as an axiom, a Real supposed to precede any position. If you begin with the Real, you can't refute the objection of the circle – that is, the Real is a *posited* Real. Laruelle posits the Real as autonomous and deduces from this axiom that thought is contingent for the Real. I believe, on the contrary, that you must begin with correlationism, then show that correlationism must itself posit the facticity of the correlation, and demonstrate in this way that this facticity is absolute contingency. Then, finally, you will accede to an independent Real. Hence, the only way to the Real, according to me, is through a proof, a *demonstration*: a demonstration unveils that facticity is not an *ignorance* of the hidden reasons of all things but a *knowledge* of the absolute contingency of all things. The simple intuition of facticity is transmuted by a *dianoia*, by a demonstration, into an intuition of a radical exteriority. I thought that facticity was the sign of the finitude and ignorance of thought. I thought I had, in facticity, a relation to my own deficient subjectivity. I discover now that what I took for human idiocy was truly an intuition, a radical intuition – that is, a relation to the Great Outside. We have a *nous* unveiled by a *dianoia*, an intuition unveiled by a demonstration. This is why I called it an intellectual intuition: not, of course, because it is an intuition which creates its object, as Kant defined it, but because it is an intuition discovered by reasoning.

I'd like to conclude with a final comparison between the principle of factuality and other philosophies in the twentieth century which tried to access a Real outside the circle of subjectivity, from Heidegger to Derrida. The main difference between these philosophies and *spéculation factuale* is that the latter avoids what I'd like to call the syndrome of a 'Real without realism'. Philosophies of the twentieth century, even when they tried to escape correlationism, generally – not always, but generally – denigrated realism, which was identified with naïve or dogmatic realism. In his book, Brassier excellently presents the significance of these ways of thinking. I quote:

> Thus for much of twentieth-century continental philosophy, from Heidegger and Derrida to Levinas and Adorno, the only conceivable alternative to the Scylla of idealism on the one hand, whether transcendental or absolute, and the Charybdis of realism – which it seems is only ever naïve – on the other, lies in using the resources of conceptualisation against themselves in the hope of glimpsing some transcendent, non-conceptual exteriority.[21]

I think we can say the following: this Real, as a non-conceptual residue of the concept, separates itself from any realism, because it forbids any possibility of a conceptual discourse about the Real in itself. We can speak about the Real as the impossibility of any conceptualisation, but we can't conceptualise the Real. There is a disjunction between the Real and *logos*. A realism is, on the contrary, according to me, a *logos* which turns to the Real instead of turning *around* it. But what do I mean by 'turning to the Real' as regards *spéculation factuale*? My thesis is that there are specific conditions of contingency, which I call 'figures'. For example, I try to show that non-contradiction is a condition of contingency, since a contradictory reality couldn't change since it would already be what it is not. The necessity of non-contradiction is for me a consequence of the falsity of the Principle of Sufficient Reason: since nothing has any reason to be and stay what it is, since everything can change without any reason, nothing can be contradictory. That is what I try to demonstrate in *After Finitude*, so that a conceptual discourse about the properties of the Real proves to be possible. We are not condemned to a 'Real without realism'. I refuse this 'Real without realism', because if I don't have a rational procedure to discover specific properties of the Real, those properties threaten to be arbitrarily posited. My own work consists in elaborating this procedure – which I call 'derivation' – grounded on the Principle of Factuality and the conditions of contingency. Producing a procedure of this sort is for me one of the main challenges of a contemporary realism.

---

[21] *Nihil Unbound*, 129.

To conclude, I would say that what contemporary philosophy lacks is not so much the Real as realism: the Real *with* realism is the true challenge of philosophy, and that's why I think that the title of our day – speculative realism – was perfectly chosen, and is in itself a sort of event.

*

Suhail Malik: If your argument against correlationism is an argument which, as you said, must be a rational argument, and at the same time, the fact upon which your rational argument turns around, is a non-absolutisable fact of the argument for contingency you make, then it seems to me that the fact that's important for your argument is that you can't have absolute reason. So I'm wondering if there's a possible complaint of resurrecting a kind of relativism, because your own reasoning has no absolute reason to it.

QM: I think that the correlationist argument is destructive of the relation to the absolute. If you want to destroy absolutism, you just have to use the correlationist argument. So my strategy is to access the absolute *through* the correlationist argument. The correlationist argument is in fact the demonstration that thinking must think itself as a relation to the absolute. Why? Because as an argument it only works if you suppose that it is possible for it to think its own facticity. But you can't think this facticity without thinking it as an absolute, because if you think that this facticity exists only as a correlate – that the facticity of thinking exists as a correlate of thinking, so thinking itself cannot be factual – facticity disappears. If facticity is a correlate of thought, thought is no longer factual. And if facticity was only thinkable as a correlate of thought, we would be – not just philosophers but everyone – idealist philosophers. We could not even imagine our dying.

Ray has a very interesting reading of Heidegger and being-toward-death. For me, it is not being-toward-death, because death is a correlate of being-in-the-world. Death cannot fight Heidegger because death is a correlate of being-in-the world and *Dasein*. So there is no being-toward-death, because if you want being-toward-death you have to conceive an event able to survive you. You have to conceive a time able to survive you, because if time disappears with you, you don't disappear. To disappear is to disappear in time. This is a demonstration, then. The demonstration of correlationism means the contrary of what it thinks it means, but it is still a demonstration. Now, what is the demonstration, what does it prove? It proves that you can destroy in me the reality of any discourse, as an absolute discourse on absolute reality, using the Rortian tactic of saying that it is contingent: 'Give me the reason why it should be a universal discourse, a universal truth, a universal reality – give me the reason. It's not possible to give a reason.' And I think it's always like that in the history of philosophy. Metaphysics and scepticism – they are always like two enemies fighting against each other, but it is always in scepticism that we discover how to realize metaphysics. Montaigne's scepticism was the key to Descartes' new metaphysics, because it discovered a new way of thinking. I think that contemporary scepticism, the contemporary correlationism, shows us where to look for the absolute. You can pursue contingency, but you can't say that facticity is a fact. If you say facticity is a fact, that even contingency is contingent, what are you saying? The only one who can say that is Hegel. But I think – it's difficult for me to show you – I think that a demonstration is possible.

I think that philosophy can be a discourse constituted by demonstrations if it renounces being a Hegelian demonstration of what there is. But, as I said to Graham, I think that it is possible to strictly demonstrate a certain truth, but this truth being the truth of the radical contingency of things, you absolutely allow for the freedom of all possible phenomenological descriptions and conceptual descriptions of the world. And effectively, I think that speculation can only take the form of this sort of demonstration. Sure, there is no reason to the world, but this absence of reason is not madness. It's not just delirium. You can have reasoning, strict reasoning, supervening on the absence of reason.

DUSTIN MCWHERTER: I want to ask you about something you said earlier. I think, when you were responding to Ray, you said that your project was one of possibility – how is it possible for science to know things about the pre-human world, such as the arche-fossil?[22] But then when you were responding to Graham you mentioned that if everything is factical – if everything is contingent it has to be factical – the only way we can know about *particular* things is through description, like phenomenological description. So my question would be: what would a phenomenological relation to something like the arche-fossil be like? How would that be possible?

QM: In *After Finitude* I try to persuade the reader with what I call 'the problem of the arche-fossil'. The problem of the arche-fossil was for me a way to write in a context principally dominated by correlationist philosophy. So I tried to show the correlationist reader – probably a correlationist – that there could be a problem in correlationism. The whole first chapter is saying: maybe there is a problem with this metaphysics … And I just demonstrate the problem like that. Correlationism is just a consequence of Kantian philosophy, and Kantian philosophy is philosophy which pretends to answer the question of how sciences are possible, how physics is possible. Okay, but the problem is that physics describes some reality which precedes the existence of the human and even that of the earth, of any living reality. So, can we explain the meaning of science without the principle of the correlationist philosophy, which says there is no science, no meaning, in affirming that reality could exist without a subjective correlate to that reality? Is the Big Bang just a correlate of a proposition? You might say, 'Ah, your Big Bang is just your correlate'. No, no I assure you it isn't. I'm not that old! There is a problem, there is a little problem here! But, in my view, there is no particular problem in description. You can describe the real fact, but you have to explain how thought is able to speak to a reality which is *not* correlated to thought. That's why my project of realism is to try to respond to the Kantian question of how sciences are possible. It is a transcendental question, but the response, the answer, can't be transcendental. It's always from the inside that I try to defeat the correlationist. It's from the inside – the arche-fossil is a way to challenge the Kantian philosophy from the inside. My problem is a problem of the meaning of the sciences. If sciences have significance, have sense, reality is not merely a correlation of thought – how can that be possible? My project is to derive from a contingency which is absolute, the conditions which would allow me to deduce the absolutisation of mathematical discourse. So it would ground the possibility of sciences to speak about an absolute reality – by which I mean, not a necessary reality, but a reality independent of thought. I mean the physical universe, which is not necessary, but which is independent of thought. There are two senses of 'absolute' here: 'absolute' in the first sense means 'absolutely necessary'. Contingency is absolutely necessary. But in the second sense, 'absolute' is that which is not essentially related to the thing. The physical universe is not necessary, in my view, but *is* absolutely independent of thought. I want to ground the possibility of these two 'absolutes'.

---

[22] For 'the problem of the arche-fossil' see **COLLAPSE** Vol. II, 15-54, 83-169.

Robin Mackay: Your argument is philosophically positive and constructive, a constructive movement; but on the plane of natural science it seems as if it could be destructive, because you begin with a position where we assume that natural laws are necessary, but we can only assume that *for us*. So, in other words, we have a working system of natural science, but always with a correlationist coefficient added to everything we say. Where we end up is with a situation where you get rid of the correlationist coefficient but instead you have the factical coefficient. So you have the absolute knowledge of contingency – the necessity of contingency – but my question is: can you then replenish this emptiness with natural science? Can you rebuild natural science from that? Because, surely, any scientific statement you make may not be valid tomorrow or in the next minute, so don't you destroy the basis of natural science at the same time as you secure a rational foundation for it?

QM: I say that everything is contingent. So laws, according to me, are contingent. They are not necessary. As Hume said, we are unable to demonstrate any such necessity. I think that irrationality, in fact, is a consequence of believing in the necessity of laws. If you believe that laws are necessary, what are the consequences? 1) You believe that laws are necessary, and 2) You are unable to explain why they are necessary. You are unable to demonstrate the necessity of laws – unless you are Hegel. So you have a mysterious necessity, and if you want to look for God in this mysterious necessity, as the anthropist does, you will find it.

I make a distinction between speculation – what I do – and metaphysics. Metaphysics is dominated by the Principle of Sufficient Reason, and the Principle of Sufficient Reason says that things are necessary. If you think that things are necessary, but you can no longer demonstrate this necessity – unless you are Hegel – then you create a mysterious entity. 'Why are the laws necessary? It's an extremely big mystery'. And this creates a lot of superstition – anthropism, providentialism, etc. 'Oh, we are astonished by the laws, they are incredible. 1) The laws are necessary, 2) They have created man – *there must be a reason*'! No, there is no reason, because they are *not* necessary. That's my response. They are not necessary. 'But how do you know that?' By reason, by my reason. Hume shows that. Hume says just use your reason, faced with the facts. Try and demonstrate that it is necessary – you can't. What does it mean? It means that reason says, 'No, it is not necessary'. And reason has said this very loudly, century after century. It is not necessary. It's just a fact. Reason can't demonstrate that it is necessary

– not because reason is deficient, but because we are mistaken in supposing that it *is* necessary. What makes us believe that these laws are necessary? Our perception, says Hume, our sociality. It's the result of experience, of the fact that laws are stable – stable, not necessary. Stability is not necessity – it's a fact, it's a fact. For example, for an insect I am very stable. If the insect lives for only three days, then I will seem immortal to it. I'm stable, more stable than the insect, but stability does not mean necessity. So, experience says there is stability, and we can say it is not necessity, and who are metaphysicians believing? Reason or perception? Reason or experience? Me, I want to believe reason, and reason says there is no reason. And I don't think this is a destruction of science. Why? Because it is, on the contrary, a rational demonstration that sciences must be empirical. Why can't physicists demonstrate the necessary determination of a law by reason alone? Because these are *facts*, not necessities. We could say, 'Yes, but with your philosophy, laws would disappear in one minute.' But this is probabilistic argumentation. And I try to show this, I try to deconstruct this reasoning, this probabilistic reasoning about the laws. I try to show that in Hume and in Kant you have this sort of reasoning. We believe that if laws were contingent they would change frequently. No, no, no, because we don't have the right to apply probability to the laws, because this would presuppose a totality of cases. But in my view there is no such totality of possibility, because the transfinite of Cantor in mathematics and set theory demonstrated that there is no quantity of all quantities.[23]

---

[23] See **Collapse** Vol. II, 55-81.

IHG: I want to ask you about the Principle of Sufficient Reason, which you use exquisitely, I think, and in a properly Leibnizian sense. The Principle of Sufficient Reason asks only that there be a reason for being, not that it be *the* reason, not that there might not be another later – only that there be one. There must be reasoning. And it seems to me that was one of the reasons why you demonstrate, both in your book and in your talk just now, considerable admiration for, and a logical or argumentative indebtedness to, the classical idealists. You have, it seems to me, an homage in your book to Schelling and his critical understanding of Hegel, for example.[24] This is in part a response to what Dustin was saying about saving the sciences, and to go back to the question that Ray raised much earlier in the day which concerns, really, the issue of revisability. We don't need to specify the quantity of sufficient reasons to be given over an infinite time. The Principle of Sufficient Reason merely states that there be *a* reason, not that it be *one* reason. That gets you revisability.

QM: Yes, of course, but I would say, the Principle of Sufficient Reason is able to support a theory of revisability – we can change our reason, etc. But there must be at least one reason. So, you can change a theory, but it is not the changing of nature. But what I am trying to do is to claim that nature can change. There is the problem of believing in the necessity of laws, but that's not the problem of believing in the necessity of theories. Nature stays what it is, but theory changes. At the beginning of the twentieth century, Newton perished and Einstein replaced him, but it is not because nature changed in 1905! So, the Principle of Sufficient Reason can extend to, can justify, the evolution of theory, yes. But I want to justify the possible evolution of *nature*.

---

[24] *Après la finitude* (AF) overtly seeks to 'renew the thinking of the absolute' (AF 39) in post-Kantian philosophy. For examples of its homage to Schelling, consider Meillassoux's differentiation of subjective from objective, or of transcendental from wild, idealism (AF 35-6); the modal extension of ontology in the form of the '*pouvoir-être*' (AF 73-80) or '*Seynkönnen*'; the asymmetrical and irreverisible temporalisation of ancestrality, factuality, and speculation (*passim*). Finally, for Meillassoux as for Schelling, Hegel is the thinker who subjugates difference to identity (AF 95). [– IHG]

IHG: So, there needs to be an additional ground.

QM: Without any reason.

IHG: Yes.

PETER HALLWARD: That was a fascinating paper. I'm confused by a very commonsense kind of problem, and I'm sure people have asked you these things many times. But it seems to me that you shuttle between an *ontological* argument that you associate with metaphysics – and particularly the metaphysics of sufficient reason, pre-Kantian metaphysics – and use that to demolish what are essentially *epistemological* arguments that underpin the correlationist post-Kantian position, where, for example, the question of necessity is much more difficult to distinguish from the status of the fact, of the factual. So the question of what is necessary about a certain factual configuration – that we necessarily breathe oxygen, or that gravity has a necessary relation between masses and so on – all those kinds of facts the correlationist says we can *know* as necessary – in other words, as having a rational justification – and so we can have an account of gravity and so on. But the correlationist position is not about the ontological status of things. For the correlationist, it's not that to *be* is to be the correlate of thought. Correlationism is just a bland epistemological argument of what we can *know* about gravity, or about evolution, or those kinds of things. And so I don't see how the correlationist would be affected by your refutation. They would simply say, 'You're telling us that we can *know* things about an absolute reality independent of knowledge', and they would simply ask you, 'Well, tell us what you know about death, or about the Big Bang, and so on, independent of our knowledge of it', and you will be able to tell them nothing. In other words, it would have the status of arguments that justify something like a negative theology: we can reason our way to knowing that there must be something about which we know nothing.

QM: Correlationism – you're right – is not an ontology, strictly speaking. The correlationist – it's true – doesn't say that reality is the correlation. It's the metaphysics of subjectivity that says that. He just says we cannot know anything apart from what we can perceive or conceive, *etc.* That's all. I refuse to say, on the contrary, that I can't say anything about the absolute. If I can deduce from the absence of reason, from contingency, certain aspects of what things in themselves must be like then I am saying something about the absolute. I know for instance that even if we don't exist, whether or not we think, things are non-contradictory. So, my problem is precisely to deduce from facticity some precise, fixed determinations which are able to explain very simple things.

When I look at this bottle, I see qualities which seem to be contingent, but in this bottle there is also something which is not visible, perceptual: its facticity. Its facticity is invisible. Only humans can conceive the facticity of the bottle, because to conceive it means to be able to ask certain questions. And facticity, I believe, is a position which is necessary for correlationism, because correlationism, ultimately, can't answer and doesn't want to answer the question of the ultimate ground. If it could answer it, it wouldn't be correlationism anymore. So facticity is a correlationist thesis. But facticity, for the correlationist, is just our *inability to conceive* the ultimate ground, not the *lack* of an ultimate ground. But what I say is that in conceiving this facticity as just ignorance, you in fact implicitly conceive the capacity of thought to conceive its own end, and thus conceive positively an event which is not dependent on its contingent existence. You – the correlationist – say, 'You cannot say anything about death'. Well, I can't say anything about what it is like to be dead, but I can speak about death as an absolute time which is able to destroy any determined entity, in which respect, the principle of non-contradiction says something about the condition of death. I don't speak of what it is *like* to be dead, of course.

Ray Brassier: That was great. It cleared lots of things up. It's just that I wonder if the argument from performative contradiction – the key correlationist argument – is as strong, as irrecusable, as you seem to be suggesting. Because the claim is that to posit something non-posited is a performative contradiction. But the correlationist must claim to know that the difference between the posited real and the non-posited real is already internal to this concept, to this act of positing. So, in other words, how does the correlationist know that there's no difference between the *concept* of an indifferent real and the indifferent real? He accuses the metaphysician of transgressing the bounds of knowledge by insisting that there's a difference between indifferent reality and our *concept* of indifferent reality, but in order to do that the correlationist must know that that difference is itself conceptual. How does the correlationist know that the difference between the concept of indifference and real indifference is itself internal to the concept? Because the act of positing itself presupposes that there's already a relation, and you must know that you exist in order to be positing, and the relation is not self positing. There's always something that seems to kind of escape and precede as a condition of positing. And in order for the correlationist to say, 'Yes, but I've already posited this difference', he must claim that this is already internal to the concept, that it's already internal to thought. In other words, it might be that the argument from performative contradiction used by the correlationist is not as robust and as devastating as they claim it is.

QM: You're asking how the correlationist knows that there is a difference between the X and the posited X?

RB: How he knows there is *no* difference – there is a difference but the difference is internal to the act of positing.

QM: In fact, the correlationist says he doesn't know, but he says that metaphysics doesn't know either. He says to the metaphysician, 'How do you know that you are speaking about the X which is essentially the same as the posited X about which you are effectively speaking? How do you know that?'

RB: Okay, but how does he know there isn't a difference?

QM: No, the correlationist doesn't say that he knows that. I will speak for the correlationist … I asked myself a question, a single question. When I was reading Kant, one day I asked myself: for Kant, are we sure that the thing-in-itself is different from the phenomenon? Because we might well think that Kant says: that the thing-in-itself is unknown doesn't mean that the thing-in-itself is different from the phenomenon, it just means that we don't know whether it is the same or not. But the Transcendental Aesthetic, in fact, says we know that the thing-in-itself cannot be the same as the phenomenon. In fact, Kant says three things about the thing-in-itself. He says that the thing-in-itself exists, that the thing-in-itself is thinkable as non-contradictory – that's what the commentators say – but in fact he also says a third thing: that the thing-in-itself is not identical to the space-time phenomenon. He knows that. He knows that by a very interesting argument which says that science can only be about phenomena. So if the thing-in-itself was phenomenal, just empirically known, we couldn't have scientific knowledge of it, because there would be no form, no subjective form which is always the same. For Kant, science is possible because we have the subjective form which is always the same: space, time, and the categories. So if science is possible, it demonstrates that we don't know the thing-in-itself – science demonstrates that we don't have any knowledge of the thing-in-itself. So, for a correlationist, Kant has an argument, a very interesting one – that we know that the thing-in-itself cannot be the same as the posited phenomenon. But I don't even say that, I don't think that. My correlationist is more modest than Kant. He just says that we don't know if the X, the absolute X, is the same as the posited X. Maybe it is the same, maybe, why not? 'But', says the correlationist, 'I don't know if it is the case or not. How could I know? How could I possibly know?' As Hegel said, you cannot surprise the thing from behind to know what it is when we are not there. If we are paranoiac we can install microphones in our house so as to know what people are saying about us when we are not there, but we cannot do that to things. Where are the things? They are not there. We cannot go outside our skin to know what is out there. Maybe the irony would be that this world is in itself exactly as it is for us – wow! In that case philosophers are absolutely useless! Maybe, maybe. Correlationism doesn't say it is impossible, it says it's unknowable.

Editorial Introduction

Robin Mackay

Surveying a century in which experience has taught us that man is capable of inventing ever more atrocious forms of violence and horror, is it necessary to remark that much of modern thought offers little to soothe, and much to exacerbate our disquiet? Nietzsche famously observed that the psychic well-being of the human organism is predicated, minimally, upon a drastically partial perspective, and ultimately upon untruth. Human cognitive defaults continue to cry out against the insights which modern physics, cosmology, genetics, neuroscience, psychoanalysis and the rest seem to require us to integrate into our worldview. As for philosophy, it has largely replaced wonder, awe, and the drive to certainty with dread, anxiety and finitude. Moreover, despite the diverse technological wonders they have made possible, the modern sciences offer little existential respite: There is no consolation in the claim that (for instance) I am the contingent product of evolution, or a chance formation of elementary particles, or that my 'self' is nothing but the correlate of the activation of neurobiological phase-spaces. Yet mundane thought, whether through obstinacy or inertia, maintains its stubborn course regardless, as if oblivious to their consequences, or at most allowing them to subsist at a safely delimited, solely theoretical level.

What if, prising the more disturbing elements of modern thought loose from their comfortable framing as part of an intellectual canon, we were to become fully attentive to their most harrowing consequences? What if, impatient with a consideration of their claims solely from the point of view of their explanatory power and formal consistency, we yielded to the (perhaps 'unphilosophical') temptation to experiment with their potentially corrosive effects upon lived experience? If the overriding affect connected with what we 'know' – but still do not really *know* – about the universe and our place in it, would be one of horror, then, inversely, how might the existing literature of horror inform a reading of these tendencies of contemporary thought?

These are some of the questions with which this volume of **COLLAPSE** sets out to grapple, imagining for a moment a philosophy absolved of humanistic responsibilities, devoting itself to the experimental marshalling of all possible resources in the service of a transformation that would no longer be circumscribed within the bounds of the purely theoretical, and thus striking an alliance with those affects which, for the most part elided, nonetheless haunt philosophical thought like its very shadow. A philosophy, then, bound to experiment with the employment of horror, that its insights might begin slowly but effectively to erode anthropic automatism.

Such experiments are already being undertaken – not for the most part by philosophers, but by those working in literature and the arts who, drawing upon the resources of modern thought, have devised means by which to produce *experiences* of the conceptual upheavals characteristic of the post-Enlightenment age. It is the scenarios of weird and horror fiction, the excessive existential sufferings of literature, the abstract emotional engineering of sound-art and music, and the poetical extrapolations of artists, that are apt to put us in the place of individuals set loose from the protective envelope of consensual reality, forced to integrate directly the lacerating force of thoughts usually blunted (even – or, sad to say, *especially* – in philosophical discourse) by the knowledge that they are, after all, '*only* thoughts'. It is through them that we identify ourselves with tormented individuals compelled – even if only momentarily – to *live the problem* of the rational corrosion of our cherished self-image, to viscerally absorb thoughts 'whose merest mention is paralysing' (Lovecraft).

In the twentieth century, SF, weird fiction, and horror in particular have furnished a laboratory for shaping narratives pointedly informed by the conceptual paradoxes produced by modern science and philosophy. And increasingly, philosophy itself, and the high arts which so long looked with disdain upon such pulp fictions, are realising with what anticipatory clarity these genres have formulated problematics which are becoming ever more pressing, not only conceptually and aesthetically, but even politically (given what is at stake in our maintenance of a naïve, comfortable self-image even as the most speculative theoretical insights are immediately and ruthlessly operationalised throughout the sociopolitical and commercial spheres, from advertising to healthcare, from warfare to banking).

Given this discursive intersection between the attempt to rethink reality through contemporary science and philosophy, and the tropes of the horror 'genre', then, there is a certain logic in examining together conceptual armature and artistic dramatisation. It was this double-edged approach that we decided to take in the present volume, by bringing together contributions from authors of weird fiction, artists, and philosophers – only to discover ourselves vindicated by the impossibility of determining where the concept ends and the horror begins. The theme thus presented an opportunity to bring more fully to fruition **Collapse**'s vision of an integration of elements originating from very different spheres, mutually catalysing so as to produce a series of conceptual 'interzones'.

George Sieg's contribution ably demonstrates how, in examining the nature of horror as an affect, a rich intersection of cognitive, conceptual, existential and political stakes comes into view. Firstly, unlike the essentially animal responses of fear and terror, horror attaches especially to the conceptual abstraction and reflexivity attendant upon self-consciousness – which is as much as to say that *homo philosophicus* is defined by a capacity for feeling horror. As Sieg argues, horror is characterised more through its victims than through its predators, and the victim's itinerary is always that from innocence to knowledge. Corollary to this is the impossibility of flight to a 'critical' position on horror, since it is 'always already' (even such hoary philosophical locutions reveal a menacing aspect here …) the horror of *knowing* horror – whence Sieg's characterisation of horror as peculiarly 'gnostic' (thus introducing a recurrent theme of this volume).

Sieg locates the historical kernel of horror in the endotropic amplification of an anthropological commonplace – the Zoroastrian concept of *druj* as xenophobia turned inward. However, in order for horror to flower, he emphasises, another element is necessary – a thoroughgoing materialism, in which the knowledge of non-apparent conceptual distinction – the sensitivity towards hidden otherness – is prevented from diffusing into mysticism: The very birth, one might say, of the distinction between philosophy and religion, is also the birth of horror. It is this compaction, suggests Sieg, which finally blocks all exit from a self-referential universe pregnant with horror and yet (or precisely because it is) entirely rational – a universe in which the innocent victim is defenceless before the monstrous knowledge which invades them.

In his contribution **Eugene Thacker** details how theology has, nevertheless, maintained a consistent historical relation to horror. His 'Nine Disputations on Theology and Horror' examines the extent to which the concept of 'life' owes its integrity to an immanent 'after-life' which is the proper object of horror. If life is defined by a duplicity – the distinction between the living being and life 'itself' – then, according to Thacker's historical survey of the 'teratological noosphere', in the undertow of the questioning of life we always find changing conceptualizations of afterlife, whose horrific avatars are so many embodiments (or disembodiments) of this problematic duplicity. They provide us with a handle on a fundamental question of biopolitics in its varying historical forms: The suppression of the after-life immanent to life, whose horror reveals that which is already there prior to individual lives, the anonymous Levinasian 'there is' which, Thacker argues, is 'a point of attraction for ontology' – in Thacker's coinage, a 'nouminous' (both noumenal and numinous) life. However as Thacker's 'disputations' deepen, the 'always-receding horizon' of the concept of life leads him to a more radical consideration of 'life as non-being', or the horror of 'life-without-Being'.

In their 'Czech Forest' cycle, Prague artist collective **Rafani** take an oblique approach to confronting a horrifying episode in their national history. Although at their birth Rafani announced themselves through overtly political manifestos, by addressing this suppressed event through a reappropriation of folk art, 'Czech Forest' displays a keen ability to navigate the borders of the political, the mythical and the aesthetic. In doing so, it adds a supplement to George Sieg's argument that horror has its roots in xenophobia and the fear of the 'enemy within'.

At the end of the Second World War, Czech inhabitants of the now-liberated Sudetenland turned on neighbouring Germans, whose families in some cases had inhabited the forest region for over a century, and drove them out with vengeful ferocity. The slogans reproduced in Rafani's iconic images (from the 'Unofficial Decalogue of Czech Soldiers in the Borderland', a propaganda handbook published at the time) demonstrate starkly enough how this triumphalist convulsion relayed the horrors suffered under occupation, revisiting them once more upon the innocent. But the 'Czech forest' of the title also conducts a deeper current: the Forest, as fairy-tale locus of darkness, where children get lost, monsters lurk, and, at dusk, branch and leaf become menacingly animate. By subtly adapting the folk-art-inspired woodcuts that often illustrate such tales, Rafani's work connects the transmutation of the rage of the oppressed into xenophobic hatred, with the mythopoetic roots of fear, thus transforming the story from national history into psychogeographical fable of horror: it becomes a reminder of what lurks beneath the comfort of homeliness, and of the horror of the internal other.

Graham Harman's emblematic invocation of 'the electrons that form the pulpy torso of Great Cthulhu' reminds us that the hard-nosed materialism that is a prerequisite for the emergence of horror finds its equally necessary counterpart in the polysemic qualifier 'pulp'. Historically describing the re-formed, low-grade paper used to manufacture magazines carrying what was, and to some extent still is, considered low-grade and derivative literature, including fantastic fiction and comics, 'pulp' came to apply also to the latter's supposedly 'generic' nature. More than coincidentally, it also sits well with what **China Miéville** nominates, in his contribution, the 'new (Weird) haptic' – a certain 'palpability' associated with horror and whose avatar, Miéville proposes, is that exemplarily 'formless' creature, the octopus – *le poulpe*. Himself a contemporary giant of weird fiction, and an unashamed champion of pulp, in his essay Miéville clearly demonstrates that an attentive reading of the history of the fantastic underpins his fiction. He undertakes to extract from their various historical combinations and scissions the two currents of the weird and the 'hauntological'. Taking the 'skulltopus' and its 'extreme rarity […] in culture' as an indicator that the coexistence of the two genres makes them no less inviolably distinct, Miéville argues that, if the rise of the weird belongs to 'crisis-blasted modernity' – the enlightenment become dark – and if in contemporary capitalism we *live* the weird, we are also haunted by ghosts of futures that never happened: the superposed temporalities of the genres expressing the tensions of post-modernity.

Disabusing us of any suspicion that the link between horror and philosophical thought is a purely modern invention, **Reza Negarestani**'s contribution recounts how a certain hideously ingenious torture was no sooner historically recorded than its most gruesome details were employed as a conceptual resource for philosophical meditation. Building on a fragment from a lost work by Aristotle, 'The Corpse Bride' launches a necrophilic investigation into the idea of ontology as a system of metaphysical cruelty which reveals vitalism to be a 'farce' played out among the remains of the already-dead.

In imbuing a famous Etruscan torture with universal pertinence, Negarestani's Aristotle becomes a prophet of terror, insistent that any intelligible ontology as such mobilises non-belonging (or nothing) through the agency of a chain of putrefactory ratios or problematic intimacies with the dead. Aristotle assimilates the bond between soul and body with the bond between corpse and living victim, wherein only the differential layer of blackening or *nigredo* can properly be called 'life'. Yet in Negarestani's argument, even this chemistry of horror is only a preface to a deeper bond with the void which Aristotle seeks to dissimulate. The final twist in Negarestani's investigation, in which the glorification of negativity or the subtractive mobilization of non-belonging (Badiou, Zizek, *et al.*) is revealed as an implicit and unconditional affirmation of the radically exterior, adds new and macabre detail to his previous **COLLAPSE** essays on absolute exteriority and 'affordance': survival becomes an art of living with the dead, of maintaining a ratio of intensive decay to extensive putrefaction, of abiding in *nigredo*.

What follows from Negarestani's probing of the problematic conjunction of *nekrous* and *philia*, the dead and the essence of affirmation, reads like a thoroughly perverse twisting of Deleuze's dialectic of problem and solution, and a retrospective 'blackening' of the history of differential calculus he associates with it: for 'what could be worse for vitalism than at once being animated through a necrophilic alliance, and simultaneously, protected under the aegis of the void'?

The work of **Jake and Dinos Chapman** has continually toyed with the cohabitation of horror and laughter, employing the debasement of form and image as a weapon against moral self-certainty. Proof of concept in this respect was achieved in their (2004) 'improvement' of Goya's famous *Disasters of War* through 'rectifications' that yanked the atrocity-victims into a cruelly absurd cartoon universe that addressed the viewer far more intensely and disquietingly than the 'originals' with their patina of historical didacticism and art-historical legitimation.

In the drawings they contribute to our volume, the Chapman brothers continue a preoccupation with the uncannily vacant images of the children's colouring book (see e.g. *Gigantic Fun* [2000]*, My Giant Colouring Book* [2004]). In *I Can See*, vulgarised Bataillean themes vie with the vacant potency of stereotyped simulacra reproduced for juvenile consumption; the comically brutal irruption into these adumbrated banalities of fragments of body-horror, and an insidious cross-breeding with the Chapmans' own stock of cartoon atrocities, engenders a menacing air of inanity that resists easy decipherment. The artists' programmatic impoverishments, testing the limit at which the image will cease to conduct the craving for improvement, might be read in the light of Negarestani's Aristotelian arithmetic as a willed acceleration of the putrefaction of the form of art, an iterative process of decay which, however, only ever momentarily disturbs the veneration of 'what remains'.

The Chapmans' extended practical joke on the art-world continually subverts any anticipation that a work should supply abreactive or cathartic moral reinforcement through didactically-framed images ('eye-care'?). Instead it invites a jarring and problematic convulsion, an irresolvable *horror vacui*.

If Lovecraft's name resounds throughout this volume, making several of his tales 'required reading' for the collected articles, it often does so through the filter of another work. Hardly a work of 'secondary literature' – despite its biographical form, it is more of a passionate affirmation and exacerbation of Lovecraft's great themes – **MICHEL HOUELLEBECQ**'s *H.P.Lovecraft: Against the World, Against Life*[1] is one of the few studies to successfully explore the singular qualities of Lovecraft's work. And, as little as it may seem evident at first, reading Houellebecq's own work through his appreciation for Lovecraft reveals a profound influence. Houellebecq's characters too live out the 'unlivable', encountering in heightened form the cosmic horrors which modern society simultaneously unleashes and suppresses; they are individuals who have taken into their very soul the full weight of what we know about our universe and our place within it. Yet unlike Lovecraft's doomed heroes, for the most part Houellebecq's remain trapped within the banal everyday: with no respite even through the negative transcendence of madness, the world becomes a relentless trial, its everyday rituals and objects beacons of desolate horror. Houellebecq's poems – a selection of which we are delighted to include in this volume translated into English for the first time – distil his powerful vision into translucid moments of dread certainty.

---

[1] Trans. D. Khazeni, San Francisco: Believer Books, 2005.

The poems record moments when the obtuse momentum of life draws it momentarily into proximity with the indifference of the universe; they offer no affirmation, no redemption, but only an icy clarity, a kind of conciliation with this indifference. The most innocuous spaces of the everyday ('the insides of cupboards') become abysmal revelations, whilst the empty repetitions of life reveal time as an implacable horror of merciless recurrence 'every day, until the end of the world'.

In his reading of the work of Thomas Ligotti – one of the foremost contemporary exponents of weird fiction – in tandem with the neurophilosophy of Thomas Metzinger, **JAMES TRAFFORD** argues that the horrifying travails of Ligotti's protagonists give phenomenological expression to insights anticipating those presented in Metzinger's extraordinary treatise *Being No-One*. The latter includes explicitly as one of its goals the achievement of a theory that can be 'culturally integrated';[2] Trafford's suggestion is that such an integration may imply a passage through horrors similar to those described – and generated – by Ligotti's singularly suffocating tales.

Metzinger's central contention is that the apparent immediacy or transparency of phenomenological appearances owes itself to an instrumental miscognition: transparency is in fact a 'special form of darkness'. Ligotti's fiction, premissed upon the catastrophic undoing of this miscognition, this protective opacity, documents the experience of the unravelling of selfhood.

Sieg argues that the monster is a less indispensable element of the horror genre than the victim, and it is the victims in Ligotti's fictions, in their plumbing of the depths of a 'spinning abyss' (recalling the 'layers within layers of horrific depravity' revealed to Sieg's gnostics) that Trafford sees as revealing the dark truth of Metzinger's 'nemocentrism'.

---

[2] T. Metzinger, *Being No One: The Self-Model Theory of Subjectivity* (London: MIT Press, 2004).

In his own contribution, **Thomas Ligotti** demonstrates that not only is self-consciousness a precondition for horror, the two are inextricable. 'Thinking Horror' is thus a pleonasm: the new epoch heralded by the dawn of self-consciousness is characterized by the production of 'horrors [and] flagrantly joyless possibilities' and – swiftly ensuing – the erection of psychic defences against truth, either explicit, socialised, or in the form of commonplace ironies and homely platitudes ('being alive is okay').

If Ligotti's fictions represent so many twisted descents into the void, here it is offered to us neat, in the manner of a classic, if unhinged, essayist, and with a certain humour indissociable from such dismal truths. Eschewing any orientation of his position according to the standard co-ordinates of a philosophical orthodoxy, Ligotti introduces us to the obscure figures who form his secret lineage of pessimism, and invents a pulp philosophy at once bracing for its brutal honesty and perversely enjoyable for its mordant wit.

Whilst much contemporary thought remains doggedly committed to continuing the perennial philosophical battle against mechanism and determinism, focusing increasingly sophisticated conceptual resources on the characterisation of 'singularities' or 'events', Ligotti aligns himself, against 'the crushing majority of philosophers', with a pessimistic creed which, refusing to imprudently postulate such exceptions, instead assigns itself the sole task of outlining the futility of man's lot and the comical details of his desperate attempts to think without thinking horror. Ligotti rightly locates the interest of this programme less in its conceptual innovation than in its audacious defiance of the snares of rhetoric and the delights of intellectual sophistication. For, rather than reason, is it not these latter passions which govern more 'sophisticated' philosophical architectonics, and in doing so obscure the conceptual vistas that might open up to those brave or foolhardy enough to interrogate philosophically the 'taboo commonplaces' which they superciliously outlaw?[3] For Ligotti, though, perhaps even such interrogations risk tainting the crystalline clarity of thinkers such as Zapffe and Mainländer, for whom the real question swiftly becomes a practical one – in a reprise of the Gnostic abhorrence of nature and will-to-extinction.

One might of course argue that, even in writing, such thinkers, and Ligotti himself, yield to the tide of life. Even the will to know, to think, and to write, may itself be a sublimated form of the *not knowing* that is crucial to survival. But if thinking and writing can themselves be sources of distraction, a thinking and writing of 'concept horror' attempts to force the reader to secrete something of the poison that is buried within them; it is a kind of demonic invocation. No less than his fictions, Ligotti's straightforward account of our 'malignant uselessness' succeeds in so far as its language – like that of Lovecraft's eldritch incantations – ceases to be representational and begins to summon the very desolate reality it describes, doing away with all cultivated distance and calm objectivity. Ligotti counsels precisely this surreptitious promotion of disillusionment, to be carried out patiently by those in every age to whom it falls to carry on the bad work, hastening the dissolution of the horrors of consciousness and life, and returning us to the void.

---

[3] A rare and fine example of such a dispassionate experiment in nihilism is Ray Brassier's recently published *Nihil Unbound: Enlightenment and Extinction* (Basingstoke: Palgrave, 2007). (See also 'The Enigma of Realism' in **COLLAPSE II**, 15-54.)

Ligotti's text appears in our volume alongside a series of photographs by **Oleg Kulik**, a Russian artist whose work includes photography and photoassemblage but which culminates in his extraordinary live actions.[4] One of the first artists from post-Soviet Russia to have garnered international attention, Kulik's work thematises the porous boundary between animal and human (a tendency which reached its infamous apex in 'Dog House' [1996] when, exhibiting himself as a chained canine, Kulik was arrested for physically harming and mentally traumatising members of the public who flouted the warning to 'beware of the dog'). As well as extending Kulik's researches into what Mila Bredikhina has called 'zoophrenia',[5] Kulik's 'Memento Mori' complexifies the dialectic of life and death, presenting us with images of creatures who are doubly dead – already corpses, their deaths have been preserved through interment in a museum. Of course, we still cannot help reading their visages as anthropomorphic signifiers, now all the more macabre. Evincing all the stuffed-shirt dignity of victorian portraiture, the photographs could also be read as an extended 'family tree' – an ancestral archive we might prefer to keep in the closet. Not only do they act as 'memento mori', reminding us of the horror of personal death; they also remind us, as does Ligotti, of the senseless and indifferent continuum of life of which we are an insignificant part, and of the absurd folly of our enshrining any part of it, stuffed and preserved, for posterity. Perhaps Kulik thus identifies in advance the museums and commemorative discourses in which his own work is destined to be preserved as cultural mausolea, even as he promotes the simultaneous fascination and horror that the mummified object, in its living death, evokes.

---

[4] See the essential *Oleg Kulik: Art Animal* (Birmingham: Ikon Gallery, 2001) for documentation of Kulik's work from 1993-2000.

[5] Ibid., *passim.*

The alternately accusing and mutely questioning faces of the dead monkeys describe a strange twisting associative dance with Ligotti's text, the nuances of dumb bewilderment and silent petition inviting us to identify ourselves simultaneously with Kulik's photographic subjects and the hapless, self-deluding targets of Ligotti's rant. A deeply felt unease, and the troubled laughter that accompanies it, is the inevitable initial response to this marriage of text and image. But ironically, read within the context of Kulik's work, 'Memento Mori' obliquely hints at an egress from Ligotti's dead end. For Kulik's performances seek a zoophrenic overcoming of the limitations of the anthropic through a plunging into the animal. The involvement of 'the point of view of different biological species in aesthetic practice,' the artist proposes, 'will produce a new renaissance'[6] – Since the anthropomorphisation of the animal can only subject it to a further death, we should rather *zoomorphise the human.* This strategy of a 'forward-to-nature'[7] zoofuturism implies that escape from 'the crisis of human schizophrenic culture'[8] might involve intimacy with a horror that walks on four legs – a horror that has left its teeth-marks on witnesses to Kulik's uncompromising and profoundly disturbing animal-becomings.

In this volume we present the final part of a 'trilogy' of essays by **Quentin Meillassoux**, which proposes a wholly different, rationalist, antidote to despair. In previous contributions, Meillassoux presented his thesis of 'absolute time' or 'the necessity of contingency', founded upon a re-examination of Hume's problem.[9] In 'Spectral Dilemma', he unveils the ethical consequences of the position, introducing the conception of the 'virtual god' that lies at the heart of the philosophical system to which the acclaimed *After Finitude*[10] – although a significant intervention in its own right – is a prolegomena. In his meditation on irremediable bereavement, Meillassoux asks, with regard both to the spectres of those whose loss is personal to us, and to those belonging to the atrocities of the last century and which seemingly cannot be dispelled, how it is possible to escape the shadow of such deaths, thus to hope once more. Meillassoux's answer to this question will surprise many, but undoubtedly constitutes a consistent development from his central philosophical contentions. Identifying the dilemma presented by the theist and atheist responses to the demands of 'essential mourning' – namely, that one must hope something for the dead, but that any *existing* god, having to be held responsible for their sufferings, can only be the object of horror and repugnance rather than veneration – Meillassoux shows that the 'impossible' conciliation of the parties must be sought through a thinking of the *divine character of inexistence*, which is further expanded into a very particular modal thesis, revealing the solution to the 'spectral dilemma' to be a formal counterpart to the speculative-rational solution of Hume's problem.

[10] Trans. R. Brassier (London/NY: Continuum, 2008).

Meillassoux presents us here with a foretaste of what he will develop of a *divinology*, in rupture with the very couplet a/theism. But if the question for the bereaved is then no longer that of having enough time to mourn, but of *what type* of time, then, glancing forward to **Benjamin Noys**' reading of Lovecraft's conception of time, we might wonder whether the god who is to come, but whose arrival depends upon a lawless 'hyperchaos', is not destined to visit upon its devotees a '*Horror Temporis*' more terrible still than the dilemma from which it frees them. Inspired by Meillassoux's conception of 'absolute time', Noys suggests that, if (as Harman argues) the comparison between Lovecraft and Kant does not hold good, at least one affinity between them may yet be attested: in the introduction into weird fiction of the affect corresponding to the 'empty form of time'. Time, released from its anthropocentric cycles, becomes unhinged and threatening in its indifference to humanity; fully purified, as in Meillassoux, of sufficient reason, it implies a 'suspension of natural laws'. Invoking the 'arche-fossil' as emblem of cosmic temporal disquiet, Noys notes that the Meillassouxian universe, freed from the yoke of the Principle of Sufficient Reason by a time whose vicissitudes are not even ameliorated by lawfulness, carries the Lovecraftian implication of a 'material "outside" responding to no law', a truly 'unmasterable' god – it is the universe of *Azathothic materialism*, releasing us 'into the experience of the horror of […] the seething vortex of time'. And, as we know, those of Lovecraft's protagonists who fall under the eldritch shadow of beings hailing from this 'outside', far from finding their hope replenished, finish traumatised and deranged. Given the trajectory of 'irrealism' which accompanies the discovery of *horror temporis,* Noys concludes fittingly by showing how Peaslee's 'researches', unsatisfactorily abridged in the ending of Lovecraft's tale, might be completed from the perspective of a contemporary philosophy of the real which reveals time itself as the 'shadow'.

German artist **Todosch**[11] (whose work, like that of Oleg Kulik, has involved an uncanny intimacy with the animal: one of his live actions, connected with the infamous 'Hundetunnel' project in Chicago,[12] involved implanting dog fangs into his mouth for a year) produces work which seems to invite myths and/or rationalisations whilst simultaneously repelling them: How to 'explain' live actions causing great public inconvenience and stress-testing public reaction (various Sisyphean labours including dragging six carriages of scrap through the streets from Berlin to the Hanover Expo); fictional institutions (*Das Falten von Böhmen*, *Conscious Force*) which realise themselves through an exhaustive documentary archive; or the painstaking production of strange objects (cute pokemon-like critters that turn out to have been carved from Carrera marble) like fetishes of a classical alien culture? A part of their disarraying force, and the irresistible desire to quell it with some narrative, results from a forced confrontation with the brute materiality of the heterogeneous matter that surrounds us but whose opacity and intractability are systematically suppressed through commodification and habituation. Refusing to make it serve him, as an artist Todosch repeatedly takes the burden of (physical, informational, cultural) 'stuff' upon himself. The drawings which he contributes to this volume of **Collapse** might be understood both as a depiction and a channeling of this heterogeneous, cloacal, sinewy, abstract matter. The 'stuff' is never quite recognisable, but is recognisably

impure, and evidently in the process either of coagulation or of decomposition – a research study from one of Todosch's fictitious institutions, *The Institute for Recycling Reality*?

Quite apart from the general ineptitude attacked by Graham Harman, there is a particular want of critical finesse in denouncing as 'continental science fiction' the work of **IAIN HAMILTON GRANT**, who his readers will know as the foremost exponent of *steampunk materialism*,[13] but who has latterly become – judging by his more recent works' protracted descent into what he has described as 'the nuclear night of the unthinged'[14] – chief scribe of *idealist horror*. In his essay on Lorenz Oken, which accompanies Todosch's drawings, Grant adds an extraordinary coda to the powerful case put in his recent book[15] for the contemporary importance of a philosophy of nature.

As anticipated in Grant's earlier account in **COLLAPSE**[16] of the necessarily speculative form of its central problem – that of accounting for its own possibility qua natural production – the chief horror of naturephilosophy is that of an evacuation of the 'comfort zone of interiority'.[17] If 'the Idea is exterior to the thinking, the thinking is exterior to the thinker, and the thinker is exterior to the nature that produced it', then naturephilosophy's vocation, in the shape of thinking the production of thought, is to turn 'us' inside out, in the process making it impossible 'for anyone to recognise themselves in the production of their thoughts'.[18] This is accompanied, too, by an unpleasant community with the lower orders, far beyond zoophrenia (and even *within* the individual – in Oken's theory of recapitulation the body becomes an infolded horror in which the head is a spine, the jaws and teeth deterritorialized limbs and nails ...).

[17] Ibid., 334, 343.

Since a universe where even thought is a natural production, its 'content' thus having no necessary purchase on that production, is indeed something 'very difficult to imagine',[19] we might say that a successful naturephilosophy would be a kind of forcible manipulation of the imagination; that it must appear in the form of a literally *mind-bending* speculative science/fiction and a brutal dismemberment of the body of representational thinking, relegating the Kantian a priori to a mere natural-historical *prius*, thought being separated from its conditions not by some absolutised transcendental membrane but by an asymmetry in the time of production.[20] Naturephilosophy thus provides the formal schema for precisely that negation of the 'insularity of transcendental subjectivity' which (as Trafford argues) is harboured by the neuroscientific viewpoint and which afflicts Ligotti's tormented protagonists.

If this gives us permission to speak of naturephilosophy as a kind of intellectual self-harm, an auto-horrification, Grant insists that against its 'better judgement', contemporary philosophy must indeed inflict this harm upon itself once again. Does post-Kantian philosophy, he asks, bowed by the blows of naturalism, dare escape the 'trap' of reasserting its 'comfort zone' through some neo-Fichtean subordination of the natural conditions of thought (irrecoverably – indeed horrifically – excessive for thought itself) to a pacificatory illusion of self-knowledge, and a resubordination of physics to ethics? In reasserting the need for a (necessarily speculative) account of nature to revoke Kant's 'daring act of reason' which ineluctably peters out into the 'ethical process', Grant selects the model in which naturephilosophy's science-fictional credentials are most ostentatiously paraded – Lorenz Oken's monstrous (in size as in content) account of the natural generation of the universe.

---

[18] Ibid., 343.

[19] Ibid.

[20] Ibid., 343.

In pursuing the ultimate ground of nature on the basis that the whole of nature is involved in each part, Oken characterises what Thacker described as the immanent 'after-life' of life as a universal Ur-slime [*Urschliem*]. But since each successive sphere of nature constitutes an appearance of 'something from nothing', then that 'nothing' appears as another element in the naturephilosophical system: Ur-slime and Zero, mucus and matheme, are thus pitted against each other as true genetic elements of nature. Grant's negotiation of Oken's twisted dialectic of Zero, the 'sink' at the 'core' of existence, and Slime as its 'oozing ground', ends in the affirmation of an 'ontological queasiness' that cannot be ceded to the hygienic instinct. In a conclusion which demonstrates the capacity of naturephilosophy to offer new and profound readings of contemporary philosophical problems – in this case that of Badiou's mobilisation of a dialectic of 'animal' and 'number' against Deleuze – Grant argues that the impossibility of abstracting away 'the shock of the objective world' means that there can be no 'slime-free matheme' unless via a unilateral assertion of the impossibility of a philosophy of nature – which would be simply to blanch squeamishly at that twisting, oozing process which *is* thinking (or being thought by) nature.

Using the search-engine as a stratigraphical probe to sample the online collective unconscious, artist **Steven Shearer** assembles vast archives (sometimes partially exhibited as works in their own right) recording otherwise uncelebrated cultural and social formations, including in particular the young fans who draw sustenance from the hyperenergetic musical genre of death metal. The *Poems* series (2001–present) draws upon an extensive archive of death metal band and song names, evidence of the genre's unremitting quest to make the cutting edges of language coincide with the violence of its sonic bombardment. Resynthesising the archive material to create a hysterical cycle of disturbing, fantastical, and absurd narratives and imagery, Shearer's well-honed method of selection yields a striking and consistent objective cross-section of this cultural matter.

Although the relentless, hysterical fervour of the *Poems* is certainly amusing at times, Shearer's work never stoops to ironic condescension. Like the lambent depictions of longhaired fans in his glowering Munch-like paintings, or in portraits which make of the humble biro an old-masterly instrument, the *Poems* are imbued with a sensitivity to a collective existential quandary whose inhabitants seek to anchor themselves to the most extreme point of reference in a world of demonstrable mediocrity. And as Shearer's *Poems* forcibly and prolongedly hold the viewer's gaze captive at the point where language is flattened out into a continuous and impassive appeal to what it can't say, his work rediscovers this extreme point. Beyond the lyrics' superficial preoccupations with death and violence lie more real and more profound depths of horror, distributed social-existential complexes rather than personal pathologies. Seen in the light of Shearer's other work – for instance, his archive of thousands of *eBay* photographs that unintentionally afford glimpses into metalheads' home lives – the evident absurdity of the *Poems*' unremitting nihilism, the distance between such extremity and 'real life', becomes an index of isolation and of the psychic torment of socialisation, showing how the metalhead's absolute 'no' to life anchors them against their inevitable concession to the tepid homeliness of 'reality'.

In their painstakingly hand-drawn form, the *Poems* have been exhibited both in galleries and in public spaces – Notably, during the 2006 Berlin Biennial, on the flank of an eight-storey building (see p. 322). Thus transformed, they invite a little of the negative sublime unapologetically celebrated by this subculture into the overlit, overfinanced spaces of the contemporary arts whose executives once told Shearer (as documented in *Sorry Steve* [1999]): 'when we talk about celebrating cultural diversity, we don't mean yours'.[21] It is through a sort of sociological alchemy that Shearer distils and recombines – so they can no longer be overlooked – the potent elements of what Lovecraft might have called a *shoggoth*-culture, with all the class associations implied in this (one of Shearer's favourite epithets for his works is 'lumpen'). Shearer's poetic invocations also echo those of Lovecraft, who considered his task to be to excite a physiological response in his readers. Again, like the famously overdone Lovecraftian prose – itself frequently verging on the comical or hysterical – the *Poems* obsessively *invoke* or *engender*, rather than merely describing, the objectless cosmic horror that inhabits every thinking being – the non-sense that ungrounds sense – but which some, by force of circumstance, are closer to than others, so that they may even cherish the secret of its constant closeness as a source of psychic sustenance.

---

[21] See the beautiful recently published monograph accompanying Shearer's 2007-8 shows in Birmingham and Toronto: *Steven Shearer* (Birmingham/Toronto: Ikon Gallery/Powerplant, 2007).

'On the Horror of Phenomenology' finds **Graham Harman** arguing, against a certain normative notion of philosophical 'maturity', in favour of the demonstrable and necessary weirdness of philosophy. Turning to Husserl's phenomenology as a test case, Harman suggests that reading its insistence on the excessiveness of intentional objects against Lovecraft's descriptive delirium might provide some pointers towards the type of 'weird realism' he advocates.

Problematising a Kantian reading of Lovecraft, Harman concurs with Miéville that a hallmark of weird writing is that it takes on the 'unspeakable' with an 'excess of specificity' in description; adding that, rather than suggesting a noumenal 'backworld', this is the excess of a *phenomenal* realm pregnant with the menace of 'malignant beings' which are threatening precisely in so far as they stalk the very same web of experience whose threads we too clamber along, attempting to ignore their more ominous vibrations.

Using literature's manufacture of unassimilable and inexhaustible objects as a model for the production of philosophical concepts, Harman insists that the latter's excess over any definition makes them, too, excessive phenomena, intentional objects whose properties can never be exhaustively enumerated – precisely the model proposed by Husserl's sensitive and meticulous phenomenology.

Reading the persistent poring of phenomenological description over its object against Lovecraft's circumlocutory evocations of the unspeakable, Harman discovers – like Negarestani – that 'real objects taunt us with endless withdrawal'. The probing of a disconnection between the 'excessive presence' of intentional objects and the withdrawing correlate that binds their qualities is the motor of both phenomenology and horror – As Miéville argues, the weird and the horrific are always palpable, but their pulpy flesh ultimately always escapes our grasp. What appears at first to be a mere similarity between literary style and philosophical programme reveals, according to Harman, a common strategy for intuiting this faultline in the object, this 'weird tension in […] phenomena'.

Kristen Alvanson's contribution presents us with a deformation produced in thought in its ongoing struggle to encompass the horror of nature's indifference to its classificatory desires. Her *Arbor Deformia* is a cross-section of a discursive phylum, the product of the baffled internal forces and tendencies of reason.

Images such as those in Alvanson's contribution (not least the fearsome 'spider-goat' [p. 366], whose branch in the *Arbor* surely neighbours that of Miéville's 'skulltopus') have always been the object of simultaneous fascination and repulsion. Her photographs capture unfortunate creatures in already preserved form, as 'doubly-dead' as Kulik's monkeys; all-too familiar, but so repugnant as to oblige us to a discursive dissociation. As she notes, they therefore seem to breed conceptual monstrosities, out-of-control taxonomical systems as deranged as the beings they are designed to corral into rational discourse. The *Arbor Deformia*, integrating the biological and taxonomical levels of this twofold teratologism, gives an inventive graphical solution to the twisted logics of Paré's sixteenth-century classifications.

It is not only Miéville's essay, whose very title exhibits the combinatorial dis-ease it discusses, that vindicates this thesis according to which, when reason turns its classificatory attentions toward monsters, taxonomy itself tends to become diseased and monstrous; in fact, Alvanson's work seems a fitting coda to the entire volume in its affirmation that one does not bring the concept to bear on horror without horror simultaneously investing the conceptual.

We would like to offer our sincere thanks to all of our contributors for their work and commitment, and for having collaborated so willingly in our experiment in concept-horror. Their enthusiasm and generosity has made possible a volume whose diversity and wealth of conceptual interconnections this brief overview has only been able to hint at. We hope that the work collected here will – in line with our subtitle – provide inspiration both for further philosophical research, and for further development in the shape of literary and artistic creations fit to assemble philosophical ideas into machines for effective deterritorialization, whether it be through the 'experiential gnosis of horror', 'multiple fraud', 'zoophrenia', 'mental experiment', 'neurotechnology', the 'shock of the objective', 'molecular disembowelment', 'necrophilic reason', the 'furtive broadcasting of disillusionment' or even, in the last resort, through 'purely medical means' … Let the horrors commence.

Robin Mackay,
Falmouth, April 2008.

Infinite Regress into Self-Referential Horror: The Gnosis of the Victim

George J. Sieg

0. DWELLING ON THE THRESHOLD

Aversion to stimuli of fear or terror, whether personal or cultural, offers no great mystery beyond the psychological. Neither does the pattern of habituation and desensitization resulting from levels of fear and terror sufficient only to gradually bore the mind and senses. Similarly straightforward is the pattern of trauma, burnout, and malady proceeding from constant and unremitting over-exposure to stimuli producing anxiety and stress. These phenomena, while intriguing to the scholar of behaviour and cognition, offer nothing to compete with the philosophical fascination engendered by contemplation of their weirder sister, Horror. She presides over a genre of art which violates boundaries of medium as surely as she violates the preconceptions of those who apprehend her; yet she shares her imageries, even her key signs and signifiers, with genres which would seem at first examination to be quite distinct.

(How often do the monsters typical of horror find their way into fantasies and 'science' fictions? The masters and progenitors of modern horror, Poe and Lovecraft, wrote tales of mystery and wonder along with their more horrific works. In the latter case, the same Mythos appeared in all of his chosen genres).[1]

Whether expressed in the cinema or in the word, or experienced viscerally in the routines or tragedies of life, Horror remains distinctly consistent, arising from an experience of cognitive dread which cannot be escaped or evaded. Indeed, this very conceptual consistency is one of its traits: Horror is the most easily self-referential of all genres.[2] Alone among concepts, Horror depends on the concept of the 'concept' for its own conceptual power – since dread *beyond what can already be known to have been conceived* is an indispensable characteristic of horror; alone among concepts, a full conception and understanding of it, implies the experience of it. Horror is not alone among those responses which require self-consciousness; animals lacking individual self-consciousness provide no evidence of experiencing horror despite their extensive capacity for fear. Of course, animals also do not seem to experience any other emotions typical of self-consciousness such as wonder, awe, or creative amusement either. Yet horror remains distinct from these others in its dependence on the capacity for conceptual abstraction. This capacity does not seem to be necessitated in the case of awe, which is known to be correlated with various ‘numinous’ states typical of religious and mystical experiences notably lacking in self-referential, conceptual abstraction; nor in the case of wonder, a response which may arise as a meta-response to a mysterious or apparently unfathomable event without any corresponding attempt to ‘conceive’ of or ‘conceptualize’ it any further. Thus it is that while children seem to display an extensive capacity for awe and wonder along with their similarly vast predilection for states of fear and terror (often to the dismay of more ‘rational’ adults), the capability to experience, appreciate, and even cultivate *horror* only *increases* with the skill of rational, conceptual, critical thought. Likewise, one may intellectually understand what numinous awe or wonder may entail, without experiencing them in the same context in which one understands them intellectually. Awe is not, in and of itself, awesome, nor is wonder in and of itself necessarily wonderful, but *horror*, self-referentially, is, of and for itself, *horrible* and *horrifying*. That this is so makes horror the most Gnostic of emotional extremes and excesses, in the sense of being a knowledge characterized by directness of empirical experience (self-referential) rather than based on some correspondent premise (other-referential). In keeping with this, it is no coincidence that those mystics and esoteric philosophers deemed ‘Gnostics’ in the increasingly decadent Imperial Roman cosmopolis elaborated mythic reflections of the world which detailed all manifest reality as nested layers within layers of horrific depravity, their ‘gnosis’ (direct, experiential knowledge) of salvation and escape implicitly depending on a nightmare network of interwoven matrix-horrors to escape *from*. The archaic roots of Gnostic horror can be followed through the labyrinthine tunnels of historic and prehistoric dualist myths, yet the experiential gnosis of horror is certainly anterior to the dualistic coping mechanisms it inspires in some persons and groups. Independently of, yet inclusive of, both *self* and *other*, Horror pervades consciousness which is conscious of itself: to observe someone sufficiently horrified is horrific. To observe a horrific other – a 'monster' – is horrific. Yet to observe oneself horrified is just as horrific, if not more so. Thus, Horror also maintains the fascinating quality of being self-renewing, for while awe and wonder may both collapse under sufficiently detached rational observation, Horror only seems to increase the more it is contemplated.

---

[1] See S.T. Joshi, *H.P. Lovecraft: The Decline of the West* (Berkeley: Wildside Press, 1990) for an extensive analysis of Lovecraft's work and philosophy.

[2] Noel Carroll, *The Philosophy of Horror, or Paradoxes of the Heart* (New York: Routledge, 1990), 17-42. Carroll's work presents a theory of 'art-horror' elaborated in exacting detail; the important aspect of it referenced here is that the horror genre depends, in his view, on its establishment of direct correlation between the emotional state of the monster's victim and the emotional state of the audience or reader. The rest of his theory is not necessarily endorsed by the rest of this article.

Yet the perpetrators and effectuators of Horror – 'monsters' in whatever form – do not seem to be guarantors of Horror even if they are its prerequisites. (And 'monsters' here means anything horrifying, not necessarily only the tentacle-beasts reviled by Lovecraft or the cinematic creations which prey on the sentiments of moviegoers.) That this is so can easily be discerned by noticing that the various beings of Lovecraft's Mythos appear throughout his own tales of wonder (such as Randolph Carter's dream quests) with the same frequency that they manifest in overtly horrific contexts in the rest of his work. They spill across the threshold not only of genre, but of authorship, to populate the worlds of Robert Howard and ultimately the annals of contemporary science-fiction in a variety of media. Lest this phenomenon be thought limited to the bizarre Old Ones of Lovecraftian provenance, the example of the vampire should be sufficient contradiction. Perhaps the most classic staple of 'gothic horror', whether cinematic or literary, vampires nevertheless also find themselves in fantasy, science-fiction, and even works classifiable only as mythic dramas (Anne Rice), not to mention their total escapist attraction in the form of gothic role-playing and subculture, neither of which exactly stimulate anything like the emotion of horror in their participants. The only consistent signifier of Horror is not the *monster*, but rather its *victim*.

What might this tell us about the nature of self-consciousness and its expression through the aesthetic? Why is it that the most direct indicator of self-consciousness combined with rational, abstract cognition, seems to be the capacity for horror, and how is it the case that this condition can only be signified aesthetically through its embodiment in a victim? Most perplexingly – and, as will be revealed through this meditation upon Horror, most horrifically – why do the perpetrators of Horror, the 'monsters', exert such an attraction upon self-conscious beings that they violate not only their victims but also the boundaries of their own genre, ultimately to become not only figures of fun and fantasy, and occasionally figures of awe and wonder in the frequent cases of religions of the monstrous or terrible, but even role-models which provide for some not only escapist pleasure, but a guide to life?

I. Exaltation of the Victim

Impaled on towering spikes, the victims of Vlad Tepes – Dracula – make apt examples of Horror's veneration of the violated. Is it any coincidence that the larger-than-life heroine-victims of the screen Dracula are likewise exalted figures? The horror is not merely one of possible identification with the damsel or hero threatened by the monstrous being; the work of Lovecraft is an excellent indication of this, desexualized as it is, and with characters stripped down to being bare instruments of perception, as Houellebecq points out in his thorough study of Lovecraftian horror.[3] Yet Lovecraft's depictions of violated observers whose very perceptions are impaled by an intrusive, inescapably bizarre alien otherness, do have something in common with cinematic preferences for innocent feminine youth across a genre inclusive of innumerable ladies of monstrous fate, murderous fate (Vivian Leigh, screen avatar of a victim conceived by an author deeply influenced by Lovecraft, Robert Bloch), demonic violation (Linda Blair, whose diabolical inhabitant was not merely a standard horned scaly devil à la Dante or Bosch, but in fact was identified in the *Exorcist* film tradition as the hideous disease-demon Pazuzu, a Mesopotamian entity worthy of Lovecraft's Mad Arab necromancer Al-Hazred and his *Necronomicon*), or demonic seduction and subversion (Mia Farrow, mother of *Rosemary's Baby*, offspring of Satan himself). Hidden within the obscure commonality here discerned is further *gnosis* of horror: let us vivisect it, and see.

Whether male or female, the ideal victim of horror is innocent, *as regards the horror*. This is not just in the usual analogical sense of being undeserving of their torment (for while many victims of fictional horror are not innocent of all wrongdoing, none could possibly deserve exactly what befalls them) but in the literal sense of previously having no *gnosis* of it. Indeed, in Lovecraft's work, it is the horrifying *knowledge* which is often itself the source of the awful consequences befalling the victim. Likewise, victims of demonic possession may theoretically have done something to invite the demon in, but do not have the 'gnosis' of it ... until it arrives. At which point it is too late to forget, or to banish the knowledge. But if horror is an emotion particular only to abstract, reasoning self-consciousnesses, why *don't* the victims 'deserve' what transpires, especially if they are guilty of something? It seems that one of the *reasons* that *reason* is required for horror, is that it is precisely *reason* which, in being violated, produces the experience of horror. Hence, the purest horror – 'concept-horror' – in which it is some *concept* which proves to be the most horrifying of all.

---

[3] Michel Houellebecq, *H.P. Lovecraft: Against the World, Against Life* (London: Weidenfield and Nicolson, 2006), 57-62, 69. (First published as *H.P. Lovecraft: Contre le monde, contre le vie* [Paris: Editions du Rocher, 1991]).

Before seeking out the most archaic formulae of such 'concept-horror', let us continue the autopsy of the horror victim. The archetypical possessed horror victim (as well as the favoured 'Satanic' sacrifice), a virgin young girl, is *in-nocent* by definition – and often expected, colloquially at least, to be blond and pretty. The significance of this, beyond the aesthetic, will be peeled back later as this morbid inquiry proceeds. It is worth inquiring: is involuntary possession always horrible? What about the identity of the possession victim? Even the lacklustre *Exorcist* prequel (still technically a horror film despite its heavy reliance on terror), set *in Africa*, ends up requiring the demon to eventually possess a European female presented as an object of desire in the course of the story. How would such a possession film fare if all the possession victims were of African identity and undefined desirability? The zombies in *Night of the Living Dead* are most successful in their assaults on innocent young women, and survived only by the black hero of the film who is finally killed when the white mob purging the zombies miscodes him as ... one of the monsters.

Leaving demons and victims of miscoding aside, further insight into the realm of horror lies in the characterization of one of the most classic horror motifs: the standard vampire-victim (or vampire love-interest). He or she begins as innocent *of the vampiric reality*, even if not virginal. Is it horrific for a vampire to prey on another vampire? Yet there is a certain commonality between the vampire, whether male or female, and its prey; the prey is likewise pale, often presented as attractive – fitted to be turned into a vampire, in fact. What about the victims of other, more inhuman, horrible monsters? While such creatures will sometimes kill indiscriminately (especially in 'terror' films as opposed to horror proper), they do seem to have an unusual taste for devouring the civilized, the self-aware, the rational: victims who are particularly innocent of the creatures' visceral realm. Even when the jungle-beast or the tentacle-monster starts eating its way through its own natives or cultists – is this alone horrific? Not enough to make a horror film out of it. Even the horror of the murder victim, in order to survive in the realm of more realist horror fiction, seems to share the signal traits: either innocence of unavoidably fitting the criteria of 'victim', until it is too late; or the equally horrible foreknowledge of unavoidably fitting that criteria; innocence of the world (physical, moral, or conceptual) from whence the horrible murderer/monster originates; and again, a cultural and racial type frequently associated with, or perhaps conflated with, 'purity'.

Why should this particular type of victim find itself exalted through an entire genre which is not even so specifically jealous of its own monstrous protagonists? And how does this relate to the conceptual nature of horror?

II. REALITY IS HORROR: THE FIRST ARYAN LIE

Of all variations on the theme of horror, what has come to be known as Lovecraftian horror is indeed the most conceptual. In some cases, Lovecraft's clinical descriptions of the utterly alien and bizarre juxtaposed with the inability of his protagonists (mere projections of the perceptive faculty) to ignore or turn away until it is too late, suffice to produce far greater horror than any description of their actual physical violation could hope to do. As Houellebecq points out, this is one reason why Lovecraftian horror is so difficult to portray through visual media,[4] though as this examination will show, the variable manifestations of horror all have an unexpectedly common conceptual trait despite their differences in regard to content. An interesting exception to the general rule that Lovecraftian films wind up being merely fantastic rather than horrible, is John Carpenter's 1995 *In the Mouth of Madness*. It manages to convey Lovecraftian horror through an almost excessively self-referential structure and plot: instead of being a Lovecraft story transplanted into a modern setting, it features as antagonist an author representing a sort of combination of Lovecraft himself and his dark prophet Nyarlathotep, whose work begins horrifically to be reflected in reality following his mysterious disappearance. One of the most memorable, and horrifying, scenes in the film involves the investigating detective trapped in a cinema watching a film that begins to depict him being assaulted by creatures reminiscent of Lovecraft's story *Dagon*. Despite the usual unfilmability of Lovecraft's eldritch horrors, *In the Mouth of Madness* captures the inescapable violation of perception, reason, and sanity which occurs in the stories, by actually using the context of film itself to reflect the self-referential, self-conscious nature of horror, when visual depictions are called for. At the same time, the constant use of embedded Lovecraft quotations, ostensibly 'fictional' even within the realm of the film, as part of the plot of the story itself, lends the film a quality of impossibility and madness which is a hallmark of Lovecraft's work. Outside the horror genre proper, a similar technique was utilized in David Cronenberg's adaptation of William Burroughs's *Naked Lunch* by including the bizarre events presaging and during the writing of the book in the plot of the film itself, thereby again using self-referentiality to evade the Lovecraftian curse of unfilmability. While the book is surreal and often disgusting, some of the scenes in the film, particularly those involving monstrous eroticism, certainly approach horror, although that may not have been the specific intent. Cronenberg's entire *oeuvre* is replete with the imagery of 'bio-horror', in which the conceptual boundaries of the flesh are violated and protagonists become their own monstrous victims – as in *The Fly* – demonstrating that the monster is not only 'interstitial', as Carroll describes,[5] but is also an instance of 'incomplete abjection', in Kristeva's sense. The conceptual boundaries of the bodily self are horrifically violated not just through destruction or even invasion, but ultimately through an inability to separate from a body that itself becomes alien.[6] As a final example, Hitchcock's films, whether suspense or horror, tend to involve frequent, if subtle, self-reference to the eye as instrument of perception, the camera as avatar of the viewer's inability to cease looking and therefore recording what is perceived (however horrible), or occasionally, to the staged or dramatic quality of events.

---

---

[5] Carroll, 31-39.

[6] Bio-horror is thoroughly examined throughout Jack Morgan, *The Biology of Horror: Gothic Literature and Film* (Carbondale: Southern Illinois University Press, 2002).

Considering the abstract nature of such perceptual ‘concept’ horror as is particularly present in Lovecraft’s work, is there any indication that his personal and aesthetic preferences, such as his Aryan racism as revealed throughout his personal biography and correspondence,[7] contribute significantly to the content of his work? Sufficient investigation has been done by others in exhaustive consideration of the role of miscegenation in Lovecraft’s cosmology, as well as his representation of inhuman, meaningless, blind cosmic Life through unnameable and indescribable ‘outer’ horrors, to establish that there is a certain analogy between the ‘penetration’ of the Aryan purity by ‘hideous’, alien, foreign elements, and the penetration of hapless Anglo-Saxon professors by tentacled predators from Outside their known reality.[8] This necessitates a corresponding examination of the philosophical ramifications of Aryan racism in the context of horror, or at least a consideration of whether such an element is indeed *indispensable* to Lovecraftian horror. But if so, is it indispensable to the whole horror genre? Or even to Horror itself? The intrusive, stark, ‘inconceivable reality’ of the concentration

---

7. In reference to New York, Lovecraft wrote in a letter: ‘The organic things – Italo-Semitico-Mongoloid – inhabiting that awful cesspool could not by any stretch of the imagination be call’d human. They were monstrous and nebulous adumbrations of the pithecanthropoid and amoebal; vaguely moulded from some stinking viscous slime of earth’s corruption, and slithering and oozing in and on the filthy streets. […] They – or the gelatinous fermentation of which they were composed – seemed to ooze, seep and trickle thro’ the gaping cracks in the horrible houses […] and I thought of […] unwholesome vats, crammed to the vomiting point with gangrenous vileness.’ This description could, taken out of context, just as plausibly be guessed as an extract from an obscure Lovecraft tale concerning the miscegenated progeny of some horrific elder or outer things.

8. e.g. Joshi, 74-80, 120-45.

camp as often remarked upon by both scholars of modern evil and the Holocaust itself seems to attest that Horror is inseparable from Aryan racism, so investigating this relationship of dependence from another vantage may prove revealing.

The first Aryans to conceive of absolute horror, the Zoroastrian dualists of prehistoric Iran, found its origins in the Mother of Abomination, *Drug,* later known as *Druj*, whose name comprises both what we would know as a 'drag-on' and also what might best be conceived as a 'simulation', a corruption of reality, whether in the form of a strategic dissimulation, a false affirmation, or an outright physical blackening as of a decomposing corpse. The word is usually translated simply as 'Lie', and was also used in the context of betrayal, such as, of an oath, promise, or contract. Why *these* Aryans in Iran as the originators of a concept of intrusive, infested, parasitic horror, propagating itself upon and within a host innocent of its nature? The *Druj*, mother of all demons and of the Devil himself, originally an abstraction, a conceptual evil knowledge, the Angstful Mind, reaches out from her primordial, prehistoric Middle-Eastern domain to eventually rip herself free from the stomachs of Aryan astronauts in Geigeresque, cinematic form as the 'alien'. Like the 'alien Mother', the Druj is horrifically and monstrously interstitial – She is fecund, yet death-producing; female, yet signified by masculine intrusiveness. She penetrates and violates like a rapist, yet she is an endless womb of darkness and depravity.[9]

---

[9] For extensive comments on femininity and gender-transgression in horror, see Cynthia Freeland, *The Naked and the Undead: Evil and the Appeal of Horror* (Boulder: Westview, 1999). See also Barbara Creed's essay, 'Horror and the Monstrous Feminine: An Imaginary Abjection', for an apt description of an 'archaic, phallic mother' reminiscent of Druj, with the Angra Mainyu as her surrogate 'male component'.

What, then, was the origin of this power – the power not of an 'image', but of a *concept* of parasitic, infectious disease-horror – over the cultural (and perhaps even philosophical) mind of the Zoroastrian Aryan, making him the very inventor of the concept of evil?

The Aryans in Iran, unlike their Vedic peers and Lovecraft both, would not seem to have had obvious justification for elaborating a traditional ethnic xenophobia into full-blown moral paranoia. The Brahmins were faced with an indigenous population whose dominant genetic traits have been proven by history to be mightier than their Aryocentric anti-miscegenation law codes. In parallel, Lovecraft was driven from New York by the dominant, successful immigrant populations. As we know, he found this experience horrific, yet in contrast, any expected 'horror' on the part of the Brahmins for the dark non-Aryan people seems to have been notably absent in India. Black Kali herself, whether an Aryan death goddess, as some claim, or the terrible indigenous mother herself, inspires simultaneous awe and terror, but not horror. The mixing of castes and the Kali-yuga, inspired woe or detached sorrow in the pure Aryans – but not horror. The Aryans in Iran, by contrast, were apparently the sole inhabitants of a desert plateau, and thus without significant competition, their recessive traits secure until Arab invasions millennia later. Lest it be suggested that a *lack* of racial competition turned their conflict-obsessed, warlike selves against each other until the prophet Zoroaster invented his horrors merely as a foil to produce cultural unity, the reader should only need to be reminded of northern Europe, which occupied itself quite consistently in a constant state of unremitting tribal warfare throughout its entire history until it was Christianized, uninterrupted by anything like a gnosis of horror, conceptual, racial, or otherwise.

It can only be that, for reasons unknown (perhaps reasons sufficiently horrific that, as in the case of Great Cthulhu and the Lovecraftian Old Ones, it may be more wholesome *not to know*), the Aryans in Iran encountered, or believed themselves to have encountered, a threat perceived to be sufficiently difficult to distinguish from themselves that it was, or *might be*, within.[10] The requisite condition for absolute horror is presented: inescapable dread, a factor which would produce constant terror – except that flight is not only impossible, but inconceivable. Conceptual horror enshrined in philosophy was then born in Iran as the Mother of Abominations. It is no exaggeration to say that by the time the moral dualism of the Zoroastrians was fully cosmologically and performatively elaborated in the *Vendidad*, their book of ritual codes and taboos against the devils, their obsession with purity – the exaltation of themselves as potential victims of intrusive, penetrative violation by Druj and her ravenous children – had reached proportions so extreme that the same ritual fixations outside of an excusably cultural or religious context would now earn a diagnosis of paranoid-schizophrenia with combined obsessive-compulsive disorder, or worse. The *Vendidad* is a study in terror if not outright horror itself. Each 'Fargard', or chapter, recites repetitively and thoroughly the number of strokes with the punishment whip a transgressor is to receive for violating any of the minutiae of purity laws, concerned with everything from moral conduct to the compulsively precise handling of corpses in order to ensure that the community and the natural world remain undefiled by the *naso-druj*, the corpse-demon. Extreme infractions, such as exposure of corpses to water or fire, result in the transgressor being publicly flayed alive. Many interesting technicalities of the Zoroastrian hygiene obsession can be found in the *Vendidad*, such as the association of albinism with uncleanness, and the rule that physicians-in-training were to practice on those who worshipped the *daevas* so as to avoid accidentally killing the faithful. Male homosexuality is so abhorred that its practitioners are proclaimed in the *Vendidad* to be demons incarnate. Sexual intercourse with a menstruating woman is an offense against purity worthy of death. Eventually, for the Zoroastrians, any being of evil thoughts, or an evil mind, might be a vehicle for Druj. This does not only include representatives of any other creed whatsoever: even those who outwardly professed the Good Religion might secretly be 'endowed with the Lie'. The incredible irony of Zoroastrianism is that the same Aryan trait of xenophobia which made the ancient Iranians amenable to this most paranoid of all world-views had to be abandoned in order for the Zoroastrian creed of absolute moral goodness in opposition to absolute moral evil to be adopted. Once the Aryans adopted the Zoroastrian religion, their enemies were not *outsiders* but *any others* (even unrecognizable others in their midst, like Drujic 'body-snatchers'), *who carried the Lie*. Even, and especially, fellow Aryans – a notion inconceivable amongst any other Indo-European group, none of which had any difficulty either with feuding incessantly with each other indiscriminately, or with uniting easily against even more foreign outsiders. Yet the Iranians became the exception, and gave the world the first universalist moral philosophy, ultimately bequeathing it to the ancient Jews, who shared with the Indo-European ancestors of the Aryans a xenophobic racism, even while the Jews lacked those recessive genetic traits the preservation of which, as signifiers of purity, inspired a racialist concept amongst the Indo-Europeans forgotten aeons ago.

---

[10] Lovecraft himself speculated on a similar process involving fear of hidden, internal others in European tradition, writing in his classic study *Supernatural Horror in Literature* (NY: Dover, 1973), 'Much of the power of Western horror-lore was undoubtedly due to the hidden but often suspected presence of a hideous cult of nocturnal worshipers whose strange customs were rooted in the most revolting fertility rites of immemorial antiquity. This secret religion, stealthily handed down among peasants for thousands of years despite the outward reign of Druidic, Greco-Roman, and Christian faiths in the regions involved, was marked by "Witches Sabbaths" […] on Walpurgis Night and Hallowe'en, the traditional breeding-seasons of the goats and sheep and cattle; and became the source of vast riches of sorcery legend.'

A comparison of the Druj to the Old Ones of the Lovecraftian mythos is intriguing, for while both concepts were invented by racists, the inventors of the former ceased to be racist as soon as they conceived their horror, whilst Lovecraft became only more vitriolic with time and exposure to foreign people. The principal difference is easily summarized: the Druj was considered to be *evil*, whilst Cthulhu, Azathoth, Yog-Sothoth, and all their various spawn, are simply *alien.* (In this, the Geigeresque cinema 'alien' is more Lovecraftian than Zoroastrian, yet as the quasi-androgynous-yet-penetrating 'demon-child' of the Alien Mother it functions much as do the daevic offspring of Druj. Unlike Lovecraft's Outer Ones, it is susceptible to physical, material defeat in a modern combat myth, and by a very un-Lovecraftian heroine who defends the moral world order against violation by both the alien outsider, and the 'Drujic' simulation-strategy of the nefarious corporation and its android agent. Perhaps more Lovecraftian in effect than Ripley's 'alien' nemesis is Norman Bates, – 'possessed by the Druj', the 'lie' of his mother, yet in that very sense his own victim and his own monster, even as he butchers his victim, who finds the purifying waters of the shower no refuge from asexual penetration by the avatar of the Outside). Lovecraft's own universe, in contrast to both of those visions, is a *horrifically* amoral one. The rational perceiver cannot escape the immeasurable, futile, imbecile meaninglessness of the blind cosmos, and is devoured by it. Yet the Zoroastrian believes that through morality (Good Thoughts, Good Words, and Good Deeds), the Druj and her children can be overcome. Ironically, in doing so, the Zoroastrian remains 'Aryan' in name only, abandoning the signifying trait of racial xenophobia which Lovecraft himself maintained – even through the absolute materialism consistently apparent in the same correspondence in which he expresses his racist views. This is not mere coincidence. Rather, it plainly demonstrates an inescapable 'Aryan truth' which is perhaps the 'Aryan horror': As long as the Aryan identifies in any meaningful way with ethnic traits which are constantly genetically embattled by competing populations, the capacity for perceiving a world of unremitting conceptual horror remains. This observation, however, fails to account for why Lovecraft elaborated, under the influence of his racial obsessions, a cosmology of absolute horror, while his equally race-obsessed Brahmin counterparts by contrast in fact ultimately presented a cosmology of all-pervading, triumphal wonderment and awe. Simultaneously, the Brahmins' Iranian cousins, originally equally xenophobic, chose to maintain their paranoia through moralism – at the cost of their ethnic fixation. It is Lovecraft's philosophical materialism which settles the matter: both the Indian Brahmins and the Iranians maintained cultural beliefs in a spiritual realm independent of the material world. Lovecraft did not.[11]

It is interesting to note that the first 'Aryan Truth' of Gotama Buddha, who rose to prominence during an age of increasing Indian rationalism and critical thinking, was that all life is pervaded with suffering, rendering theism irrelevant. For Lovecraft, thoroughly atheistic and avowedly soulless, it was not just suffering, but utter horror. Yet his ultimate rejection of the opportunity to write Nazi propaganda in the pre-war decade, and his rejection of Nazi atrocity and genocide, demonstrates something else: while Lovecraft's cosmos was a brutal one, he was not himself maltheistic[12] enough to embrace such a conception with participatory enthusiasm.[13] He did not want to contribute to the world of horrors; rather, he rejected life. If he had believed in a soul, he would have been a Gnostic dualist, but even this option was closed to him in his atheistic materialism. (The Gnostics, while rejecting the supposedly-divine 'archons', the spiritual creators of, and rulers of, the material world of horrors, asserted an all-Good, all-perfect, spiritual reality of divine emanations beyond it; an option totally unacceptable to Lovecraft's materialistic 'cosmicism').[14]

[11] Joshi, 7-45.

---

[12] In contrast to *dystheism*, which merely supposes that the deity is not good, *maltheism* proposes that the deity is actively and intentionally malicious. It should be noted that neither of those alternatives specify whether or not it is advisable to venerate the deity in question. The Zoroastrian Church condemned two maltheistic sects, one of which, called the *daevayasna*, was accused of venerating the Druj, Ahriman, and the *daevas* apotropeically – that is, with the intent to placate or banish them. The other sect, that of the *yatukih* sorcerers, was accused of actively honoring the evil principles with the intent to gain power from doing so: the original example of what the Christian world knows as the 'pact with the Devil'. It remains unclear whether or not the yatukih also recognized the existence of a 'good' deity opposing Ahriman and the Druj, and if so, whether they ignored him, or actively opposed him. (Or whether they acknowledged him as good at all). It seems that the Lovecraftian cults of the Old Ones would qualify as maltheistic only in the 'Derleth recension' of the Cthulhu Mythos, since only that later, dualized version of Lovecraft's cosmology promotes the Elder Gods as moral opponents of the Old Ones. It may be possible to consider some forms of monotheism to be necessarily maltheistic, when an understanding of the god is offered in which its omnipotence (or ultra-potence, in cases in which it is more powerful than any other being or beings combined, but not actually all-powerful) is not only greater than its benevolence, but uncompromised with any notion of benevolence whatsoever. Within such possible monotheistic conceptions of a non-benevolent god who is either the only god or the supreme one, a further distinction may perhaps be drawn between *apotropaic maltheism*, in which the god or deity is venerated in the hope that its malefic attention may be turned away, *contractual maltheism*, in which the power is venerated in order to increase one's standing, stature, or power within its reality or domain, and *latreic maltheism*, in which it is actively worshipped or adored in a sort of religious Stockholm-syndrome, a compulsive response to its irresistible but awful or malign numinosity. A sub-category of latreic maltheism might be *propitiatory maltheism*, in which it is supposed that the malice of the divine being can be mollified in some way even if not actively averted, as in the case of apotropeic maltheism. It should be noted that this typology of maltheism could easily be mirrored with reference to dystheistic demon-cults in which destructive (but not intentionally malicious) powers are venerated for the aims or reasons described. The disease-demon Pazuzu, for example, was viewed as dangerously destructive most of the time, as was the even more feared child-slaying Lamashtu, but there is

---

no indication that either one was understood to murder human beings sadistically or for the purpose of deriving pleasure specifically from harming people. In this sense, the difference between dystheism and maltheism could be likened to the difference between honoring man-eating beasts (or an advanced race of amoral extra-terrestrials, for a more 'godlike' analogy) and honoring serial or mass-murderers (or, to continue the analogy of 'advanced' beings, a race of creature that hunts human beings for sport or pleasure).

13. While it might be considered questionable to assert that the Nazi philosophy is maltheistic since 'Providence' or the 'Gott-force' in Nature was understood by the Nazis to support Aryans and cause them to flourish, it would certainly have been perceived as maltheistic by Lovecraft. He was married to a Jewish woman, reviled violence and cruelty, and was too materialistic to have considered theological justifications for killing as are found in the *Bhagavad-Gita*, in which the god Krishna reveals to the story's protagonist that he should have no regret over killing even those for whom he feels respect or affection since all beings are merely projections of an ultimately indestructible Self. Himmler was reported to have frequently carried a translation of this text – and was presumably not, for this reason, a maltheist, despite his affection for the imagery of death. The ideology of those Jews who willingly cooperated with the Nazi regime (especially any who cooperated with the SS) could easily have been described as one of the forms of maltheism proposed above, however, particularly in cases wherein the plight of the Jews was understood to have been sent as divine retribution, since modern Jews, unlike their ancient predecessors, generally regard Yahweh as omnipotent (thanks to Zoroastrian influence identifying Yahweh with the omnipotent Zoroastrian god, Ahura Mazda, subsequent to their liberation by Cyrus the Great and his Zoroastrian Persians, from captivity in Babylon). It is perhaps this potential for maltheism within monotheism that led to the famous 'trial of God in Auschwitz' account of Elie Wiesel, and the various elaborations of 'Holocaust theology' in modern Judaism.

14. Ironically, the earliest Gnostics themselves seem to have been Hellenized Alexandrian Jews, probably expatriate in the wake of the second Jewish revolt under

The Zoroastrians, however, maintained their spiritual beliefs despite their conception of the 'life-horror' of Druj. They only conceived of such horror in the absence of the simple othering process that gave rise to the Vedic caste system, or the assimilation of local populations that characterized the gradual Indo-European drift into Europe. Instead, whatever ethnic or cultural influences threatened the ancient Iranians, these threats must have been perceived as *outwardly* indistinguishable from the Aryan population, requiring a new concept in order to maintain Aryan self-other polarity. That concept: horror – mother of absolute dualism; as Druj, Mother of Abominations. In identifying that which was 'other' than the ambiguity of the life of flesh, the Zoroastrians also invented the Iranian version of the Indo-European cognitive dualism. In contrast to societies of gradual, graduated ethnic mixture wherein this perspective manifested as mind-body dualism, in *apparently* homogenous Iran, it manifested as *moral* dualism. Instead of an escape from the embodied world, as sought by Orphics, Gnostics, and yogis alike, the Zoroastrians conceived of immortal youth in a perfected, resurrected body, inhabiting an eternally perfected world of monotonous, sterile cleanliness and light, given to Ahura Mazda's faithful as a reward for moral behaviour. For Lovecraft, materialist that he was, no such solace could be found either in

---

Trajan, who particularly reviled the God of Israel as an evil 'demiurge'. See Carl B. Smith II, *No Longer Jews: The Search for Gnostic Origins* (Peabody: Hendrickson, 2004), for details. They generally abominated the whole material cosmos, but proposed a transcendent spiritual escape, in a manner similar to the renunciation of the round of rebirth by Indian philosophers seeking liberation, and to the earlier Orphic mystics. While all these philosophies share in common an origin in the collision of Indo-European and non-Indo-European cultural patterns, only Gnosticism seems to have originated amongst people who were themselves an ethnic out-group within an Indo-European society – and it is only Gnosticism which proposes not only a binding and malignant material world, but a malicious creator-god as its origin.

spiritual transcendence or eternal life through resurrection. In a great biographical and historical double irony, Lovecraft the racist married a Jewish woman, Sonia Greene, exempting her from his xenophobic tirades – yet his materialism historically descended from a rationalistic response to Judaeo-Christianity, the offspring of Zoroastrian dualism and Semitic culture.

III. Purity

> There can be no reversing the unique tragedy of the Holocaust. It must be remembered, with shame and horror, for as long as human memory continues. Only by remembering can we pay fitting tribute to the victims. (UN Secretary General Kofi Annan, observing International Holocaust Remembrance Day on January 27, 2006, anniversary of the liberation of Auschwitz-Birkenau by the Soviets.)

Now archetypal symbols of human evil, often regarded as actually living embodiments of absolute horror, the Nazis are strangely absent from fictional horror, while their presence (or their equivalent, such as Palpatine's Galactic Empire of *Star Wars* fame) is surreally commonplace alongside various more eldritch monsters in the annals of fantasy and science-fiction. Additionally, Occult Nazism is a staple of fringe conspiracy lore and pseudo-esoteric crypto-history, and Nazi super-villains and super-sorcerers of some variety are by no means infrequent adversaries in occult fiction and suspense thrillers. This alone is peculiar, since surely the Nazis are regarded as infinitely more horrific, in carnal reality, than any serial murderer one could name – yet not a single horror-genre film of any significance has ever featured someone racially motivated to prey on non-Aryan victims, much less featured an actual Nazi as its antagonist.

(The infamous 'Nazi exploitation' genre of course excepted – save that it qualifies more as pornography than horror.) More peculiar still is the occasional association, in occult and fantasy/science-fiction, of said Nazi super-villains with black magic, 'Satanic' rites, and the conjuration of terrible ancient monstrosities blatantly reminiscent of Lovecraft's Mythos. (The tentacled horrors emerging from the abyss in the *Hellboy* comics and films with the assistance of Nazi sorcerers and Rasputin serve as an excellent example.) Beneath the apparently superficial aesthetic of the pop-culture sensibility lurks something of significance: the same perpetrators of violence and horror – whether evil Nazis or Cthulhu monsters – are determined to be figures of either *horror* or *fantasy* based specifically on the identities of their *victims*. Thus, while Lovecraft's violated professors are often stripped of all significant personality and traits, even of any references to sexuality, they remain *Anglo-Saxon* professors, horrified by the miscegenated, bestial realities they confront. In fact, so long as they are not engaged in the violation of Lovecraft's ideal Aryan scientists (modeled more or less after himself), the very same tentacular Old Ones somehow desist from being figures of actual horror, instead crossing genres and winding up being summoned for genocidal purposes by more murderous Germanic professors in the vein of Mengele and Himmler, whose racial sensibilities, if not their ethics, Lovecraft embraced. It would seem that *horror* as it is generally appreciated within contemporary culture not only requires victims identifiable with the originating ethno-cultural group, but also depends upon the total disassociation of the monster from possible identification with such victims. That is, horror requires both a Zoroastrian dualism, and the maintenance (at least cryptically) of the racialism the Zoroastrians themselves rejected in order to avoid the horror. The work of Lovecraft represents a striking testament to the fact that, from the perspective of the Aryan racist, the manifest physical world is a whole *world of horror*, a reality not just of terrible strife, or frightful competition for resources, but indeed an inescapably dreadful experience of *invasion from without*.

This phenomenon of belief provides further demonstration that the Nazi preoccupation with 'Jewish materialism' and with the supposedly insidious nature of Jewish sexuality as virally infecting, perverting, and corrupting the otherwise pure German race, was by no means an artifact of Christian morality combined with political expedience. For the Zoroastrian Iranians also displayed a paranoid response to confrontation with influences perceived as invasive from without and hidden within. The Nazis, however, despite all their dualistic propaganda, rejected the solution of moral dualism, preferring instead consciously and willfully to become embodied perpetrators of absolute horror upon their presumed infiltrators. While Nazi propaganda depicted Jews in verminous terms, and displayed the octopus-tentacles of the Elders of Zion insinuating themselves upon defenseless globes and world-maps, the Nazis did not depict Jews as externally menacing, mighty demonic beings with huge armies of Satanic devils at their disposal, capable of opposing the Aryan legions on equal footing. While the Nazis presented the 'hordes' from the Communist east as threatening mobs of 'sub-humans', such mobs were certainly not depicted as mythically comparable to the bewitching majesty of the Angstful Mind and all the monstrous and terrible children of the Druj. Stalin was no Ahriman, at least not to the Nazis. Rather, the self-proclaimed elite of the Nazi party, Himmler's SS, reveled in its own imagery of death, and glorified in the extermination not of mighty evil foes, but of *weakness*, both in themselves and in others. In simple terms, they chose to act the part of their own monsters. It is an irony of history and human thought that the Nazis' chosen victims had become the world's most loathed yet sometimes venerated ethnic group aeons previously, only after combining their own xenophobia with a moral dualism invented by Iranian Aryans for the purpose of adapting their own racism to an as yet unidentified, invisible enemy. Yet, despite the clearly monstrous nature of Nazi policy, Heinrich Himmler is often quoted as remarking that the real Nazi 'triumph' lay in their performance of horrific deeds while remaining otherwise humane and uncorrupt – at least in their own minds, the SS represented less a Stockholm-syndrome style identification with and veneration of 'life-as-horror', and more an attempt to somehow buy off 'life-horror' through mass offerings of victims rendered suitable due to the Jewish adoption of post-Aryan moral dualism as an ethical philosophy augmenting the Jews' preexistent ethnic exclusivism.

Still, even as the Nazis remain the most morally demonized of all possible monsters, the exaltation of the pure white victim remains consistent and genre-inviolable: evil as the Nazi may be, the monster violating the same lovely blondes who could well be the Nazi ideal of beauty, is *horrible*. Lest the association of arcane horrors with monstrous-Aryans-gone-bad (rather than Aryan victims violated) be thought a post-war consequence, consider that Dracula, the vampiric horror icon, is based on a figure of Romanian history considered a local hero of Christendom, utilizing the *horror of impalement* as a deterrent against invasion by foreign *others*, the non-Aryan Turks. Even the

Zoroastrians were racist, albeit sporadically, when fighting Central Asian adversaries. Lovecraft was not beyond re-appropriating monstrous imageries in a non-horrific context to make his racist point. His pentacular Great Old Ones with their asexual lost civilization, eventually overthrown by their own decadent progeny, resonate in strange kinship with the human researchers who discover their remains beneath the Antarctic ice – a closer kinship than those researchers would have had to fellow humans whom Lovecraft would have called 'inferior stock'. Such a demonstration of the ultimate identification of the monstrous with Aryan purity need not be considered completely tangential in Lovecraft's work, however. In one of his more unusual tales, somehow one of wonder and horror simultaneously, Lovecraft's bare instrument of perception, the narrator, discovers itself to *be* the monster. In this short story is collapsed and compressed the full gnosis of the Aryan truth of horror, ultimate originator of both the moral dualism and the renewed Aryan dualism of absolute racial superiority, and of self-victimization, as an antidote to perceived weakness. The purest form of conceptual horror is the realization of inescapable identity with the monstrous perception – the concept – which is both the object and source of horror. Yet, when that object of horror is also the subject, the instrument of perception, wave upon wave of self-referential, cascading horror is the result. Zoroastrian dualism provides one solution – a 'good' spiritual identity for the self, an 'evil' spiritual identity for the other, horrific only in 'this world'. Nazi racism provides the other solution – 'evil' deeds of horror performed by the self as a displacement of the horror of invasion by the other, the pure becoming the monstrous: the self-exalted victim, the now-monstrous Aryan; the reality victim, the scapegoated Jew. For Lovecraft, though, as for any Aryanist materialist, there was no solution or escape from the horror, as becoming the monster through deliberate identification is hardly an option for the extreme reductionist. For him, life is a conceptual nightmare with only the void of an empty consciousness as contrast.

Nine Disputations on Theology and Horror

Eugene Thacker

1. After-Life

Ever since Aristotle distinguished the living from the non-living in terms of *psukhê* – commonly translated as 'soul' or 'life-principle' – the concept of 'life' has itself been defined by a duplicity – at once self-evident and yet opaque, capable of categorization and capable of further mystification. This duplicity is related to a another one, namely, that there are also two Aristotles – Aristotle-the-metaphysician, rationalizing *psukhê*, form, and causality, and Aristotle-the-biologist, observing natural processes of 'generation and corruption' and ordering the 'parts of animals'.

Arguably, the question of life is the burning question of the contemporary era, one in which life is everywhere at stake as 'bare life', one in which 'all politics is biopolitics'. If the question of Being was the central issue for antiquity (raised again by Heidegger), and if the question of God

– as alive or dead – was the central issue for modernity (Kierkegaard, Nietzsche), then perhaps the central question today is that of Life – the function of the concept of 'life itself', the two-fold approach to life as at once scientific and mystical, the return of vitalisms of all types, and the pervasive politicization of life.

The question that runs through these brief *disputatio* is the following: Can there be an ontology of 'life' that does not immediately become a concern of either Being or God? Put differently, if one accepts that the concept of 'life' is irreducible to biology, what then is to prevent it from becoming reducible to theology? Let us be even more particular: To what extent is 'life' as a concept always situated between a biology of a non-ontological 'life itself' and an onto-theology of the life-beyond-the-living, or 'after-life'?

But what comes 'after life'? Is it death, decay, and decomposition, or is it resurrection and regeneration? Is it, in biological terms, the transformation of the living into the non-living, from the organic life of molecules to non-organic matter? Or does it involve a theological re-vitalization of the resurrected, living cadaver? In either case, the after-life bears some relation to the 'during life' and the 'before life', and it is precisely the ambiguity of these relationships that has shaped the debates on mechanism and vitalism in the philosophy of biology, as well as the earlier debates in Scholasticism on the nature of creaturely life.

There is no better guide to the after-life than Dante. The life of the after-life in the *Commedia* is a political theology, at once rigidly structured and yet coursing with masses of bodies, limbs, fluids, fires, rivers, minerals, and geometric patterns of beatific light. In particular, the *Inferno* gives us several concise statements concerning the life of the after-life. In the seventh circle, Dante and his guide Virgil come to the 'burning desert', upon which a multitude of bodies are strewn about.[1] Among them Dante and Virgil come across Capaneus, one of the seven kings who assaulted Thebes and defied the law of Jove. Capaneus lies stretched out on the burning sand, a rain of fire descending upon him, while he continues his curses against the sovereign. As Virgil explains, Capaneus is one of the blasphemers, grouped with the usurers and sodomites for their crimes against God, State, and Nature. But, as with many of Dante's depictions in the *Inferno*, there is no redemption, and the punished are often far from being penitential. Their tired, Promethean drama of revolt, defiance, and blasphemy goes on for eternity.

It is easy to read such scenes in a highly anthropomorphic manner. But each individual 'shade' that Dante encounters is also associated with a group or ensemble that denotes a category of transgression, and this is especially the case of Middle Hell. Upon entering the gates of the City of Dis, Dante and Virgil are first confronted by a horde of demons, and then by the Furies. Once they are able to pass, they come upon a 'landscape of open graves', each one burning and holding within it one of the Heretics. The scene is visually depicted with great drama by Gustav Doré, who, following the prior example of Botticelli, presents the heretics as a mass of twisted, emaciated corpses emerging from their graves. Along the way they also encounter a river of bodies immersed in boiling blood (watched over by a regiment of Centaurs), as well as the 'wood of suicides', in which the bodies of the damned are fused with dead trees (watched over by the Harpies). Within many of the circles, Dante encounters nothing but multiplicity – bustling crowds (the Vestibule of the Indecisive), a cyclone of impassioned bodies (Circle II, the Lustful), a sea of bodies devouring each other (Circle IV, the Wrathful), dismembered bodies (Circle VIII, the Sowers of Discord), and a field of bodies ridden with leprosy (Circle VIII, the Falsifiers). The life-after-life is not only a life of multiplicity, but it is also a life in which the very concept of life continually negates itself, a kind of vitalistic *life-negation* that results in the living dead 'citizens' of the City of Dis.

---

[1] Cf. XIV, 22-24: 'some souls were stretched out flat upon their backs,/others were crouching there all tightly hunched,/some wandered, never stopping, round and round' (*Inferno*, trans. Mark Musa, Penguin, 1984; all citations refer to this edition).

Perhaps, then, one should begin not by thinking about any essence or principle of life, but by thinking about a certain negation of life, a kind of life-after-life in which the 'after' is not temporal or sequential, but liminal.

2. Blasphemous Life

But we've forgotten about blasphemy. What is blasphemy in regard to the forms of life-negation found in the *Inferno*? Returning to the burning desert, Capaneus, noticing Dante's inquiring gaze, shouts back to him: 'What I was once, alive, I still am, dead!'[2] On one level this is simply a descriptive statement – defiant towards divine sovereignty in life, I remain so in the after-life. But surely Capaneus realizes that, after life, resistance is futile?[3] Or have the terms changed, after life? Perhaps his words do not mean 'I am still defiant' but rather, quite literally, something like

---

[2] XIV, 51. An alternate edition by Mandelbaum translates 'Qual io fui vivo, tal son morto' thus: 'That which I was in life, I am in death.'

[3] Virgil notes as much, chastising Capaneus for continuing this tirade, his own words becoming his own punishment.

'I am a living contradiction.' Such phrases denoting a living-death recur in the *Inferno*, often spoken by Dante himself.[4] Perhaps, then, this phrase 'What I was once, alive, I am still now' actually means – in the afterlife – that 'I am still living, even in death.' This living contradiction – being *living dead* – is also linked to the political-theological contradiction of a power that at once 'shuts down' as much as it 'lets flow'. There is a kind of Medieval biopolitics in the *Inferno* quite different from the modern, Foucauldian version. The strange conjunction of sovereignty and multiplicity in the *Inferno* does not demand the punishment of souls, but instead requires a mass of animated, sensate, living bodies, in some cases resulting in an almost medicalized concept of the after-life (e.g. the Sowers of Discord are meticulously dismembered, dissected, and anatomized). In tandem with a sovereign 'shutting-down' we have also a kind of governmental 'letting-flow'; indeed, at several points the *Inferno* seems to imply their isomorphism.

Blasphemy, then, can be viewed in this regard as the assertion of living contradiction. But this assertion is not simply a resistance to an authoritative demand to be non-contradictory. In its modern variants it strives to become an ontological principle as well. Nowhere is this more evident than in the 'weird biologies' of H.P. Lovecraft's *At the Mountains of Madness*.[5] The narrative describes two kinds of blasphemous life. The first involves the discovery of unknown fossils and a 'Cyclopean city' in the deep Antarctic, both of which display 'monstrous perversions of geometrical laws'.[6] The discovery leads to the remains of an unrecognizable, intelligent species of 'Old Ones' that, in the Lovecraftian mythos, are thought to have lived eons prior to the earliest known human fossilized data.[7]

---

[4] Upon seeing the bestial figure of Satan, Dante notes 'I did not die – I was not living either!' (XXXIV, 25).

[5] To this one might also add the creatures that inhabit William Hope Hodgson's *The Night Land* as well as weird tales of authors such as Clark Ashton Smith and Frank Belknap Long.

But this only leads to a further revelation, in which the explorers discover another type of life which they call the Shoggoths and which seem to resemble formless yet geometric patterns: 'viscous agglutinations of bubbling cells – rubbery fifteen-foot spheroids infinitely plastic and ductile – slaves of suggestion, builders of cities – more and more sullen, more and more intelligent, more and more amphibious, more and more imitative [...] '[8] In Lovecraft's inimitable prose, the Shoggoths are the alterity of alterity, the species-of-no-species, the biological empty set. When they are discovered to still be alive, they are described sometimes as formless, black ooze, and sometimes as mathematical patterns of organic 'dots', and sometimes as a hurling mass of viscous eyes. Formless, abstract, faceless. In an oft-referenced passage, what the narrator expresses is the horizon of the ability of the human characters to think this kind of 'life':

> When Danforth and I saw the freshly glistening and reflectively iridescent black slime which clung thickly to those headless bodies and stank obscenely with that new unknown odor whose cause only a diseased fancy could envisage – clung

[7] One could easily imagine a re-casting of Quentin Meillassoux's 'arche-fossil' in terms of the findings of the Miskatonic University Expedition. See William Dyer et al., 'A Hypothesis Concerning Pre-Archaen Fossil Data Found Along the Ross Ice Shelf', *The New England Journal of Geological Science*, 44.2 (1936): 1-17.

[8] *At the Mountains of Madness*, 330.

> to those bodies and sparkled less voluminously on a smooth part of the accursedly resculptured wall in a series of grouped dots – we understood the quality of *cosmic fear* to its uttermost heights.[9]

What Lovecraft puts forth in his tales of cosmic horror is a form of blasphemy that is decidedly non-anthropomorphic and misanthropic. At the mountains of madness we move from a concept of blasphemy as grounded in human agency (the blasphemy of Capaneus in the underworld) to a blasphemy of the unhuman ('more and more amphibious'). For Lovecraft, 'it' is blasphemous – but also indifferent, incomprehensible, and in many cases unnamable ('the thing', 'the doom', 'the fear', 'the whisperer').

At the center of blasphemous life is this idea of the living contradiction. *Blasphemous life is the life that is living but that should not be living*. This contradiction is not a contradiction in terms of medical science; the blasphemous life can often be scientifically explained and yet remain utterly incomprehensible. If it is a logical contradiction, it would have to be one in which the existence of true contradictions would not only be admitted, but would be foundational to any ontology. In logical terms, the assertion that there are true contradictions is often referred to as 'dialetheism'.[10] But with Lovecraft we have a twist. The Shoggoths are bizarre examples of *dialethic biologies*, contradictions that are living precisely because they are contradictory, or 'blasphemous'.

---

[9] Ibid., 331.

[10] In its simplest form, dialetheism argues that for any proposition *X*, both *X* and *not-X* are true. Dialetheism therefore works against the Law of Non-Contradiction (articulated in Aristotle's *Metaphysics* Gamma), but, in order to avoid accepting absolute relativism, it must also accept some form of paraconsistent logic. For more see Graham Priest, *In Contradiction* (Martinus: Nijhoff, 1987).

Whereas for Dante the blasphemous is the living contradiction – to be living in death, to be living after life – for Lovecraft the blasphemous is the very inability to think 'life' as a concept at all. Blasphemy is here rendered as the unthinkable. To account for such blasphemous life, one would have to either compromise existing categories of thought, or entertain contradictory notions such as 'living numbers' or 'pathological life'.

3. AMBIENT PLAGUE

The anonymous 'it' of blasphemy is also expressed in the hermeneutics of plague and pestilence. Our very concepts regarding the disaster already betray a profound anxiety. That some disasters are 'natural' while others are not implies a hypothetical line between the disaster that can be prevented (and thus controlled), and the disaster that cannot. The case of infectious diseases is similar, except that the agency or the activity of this 'biological disaster' courses through human beings themselves – within bodies, between bodies, and through the networks of global transit and exchange that form bodies politic. In the U.S., the two-fold conceptual apparatus of 'emerging infectious diseases' (naturally-caused) and 'biodefense' (artificially-caused) cloaks a generalized militarization of public health. More fundamentally, when it becomes increasingly more difficult to discern the epidemic from the bioweapon, entire relations of enmity are re-cast. The threat is not simply an enemy nation or terrorist group, the threat is itself biological; biological life itself becomes the absolute enemy. Life is weaponized against Life, resulting in an ambient *Angst* towards the biological domain itself.[11]

---

[11] Cf. my article 'Biological Sovereignty', *Pli: The Warwick Journal of Philosophy* 17 (2006-7).

However, while it has become customary to view epidemics in light of post-germ-theory 'autoimmunitary' boundary disputes, there is a more fundamental problem articulated in the pre-modern concept of plague and pestilence, where biology and theology are always intertwined in the concepts of contagion, corruption, and pollution.[12] One of the central concerns of chroniclers of the Black Death was that of causation, and how that causation was interpreted in relation to the divine.[13] As the Black Death spread throughout Medieval Europe, the motif of the 'angry God' recurs in many of the chronicles, both fictional and non-fictional. It forms a key framing-tool for Boccaccio's *Decameron*, is a motif in *Piers Plowman*, and it shapes the sub-genre of plague pamphlets in England.[14] These in turn make reference to the examples of Biblical plague, of which the most well-known is the Ten Plagues of Egypt, in which God sends down ten 'plagues' to persuade the Egyptian pharaoh the free the Jewish people.[15]

---

[12] A great deal of the cultural theory surrounding epidemics has focused on its modern, germ-theory context. Emily Martin's *Flexible Bodies* (Boston: Beacon, 1994) and Laura Otis' *Membranes* (Baltimore: Johns Hopkins University Press, 2000), provide views from anthropology and literary studies, respectively. Jacques Derrida noted the way in which political conceptualizations of the enemy have, in a post-9/11 era, centered around autoimmune disorders, in which the threat comes from within. See Giovanna Borradori and Jacques Derrida, 'Autoimmunity: Real and Symbolic Suicides – a Dialogue with Jacques Derrida', in *Philosophy in a Time of Terror* (Chicago: University of Chicago Press, 2003). However, there is as much to learn from the pre-modern discourse of plague and pestilence, which often de-emphasizes the ontology of interior-exterior in favor of a theology of life and life-after-life.

[13] For a survey, see the collection *Epidemics and Ideas: Essays on the Historical Perception of Pestilence*, edited by Terrence Ranger and Paul Slack (Cambridge University Press, 1992).

[14] A particularly good example in this regard is William Bullein's mid-sixteenth century plague pamphlet, *A Dialogue Against the Fever Pestilence*.

[15] *Exodus* 7:14-12:42.

Here the ‘plagues’ do include epidemic disease, but also rivers that turn into blood, swarms of insects, tempestual storms, and an eclipse. Another, more common reference among the Black Death chronicles is apocalyptic. *Revelations*, with its dense and complex symbology, tells of ‘Seven Angels’ sent forth to deliver ‘Seven Plagues’ that are to be ‘poured’ upon mankind as a form of divine judgment; here again the ‘plagues’ range from contagious disease to aberrations in livestock, the weather, and the destruction of human cities.[16]

In all these instances we see this key element: a divine sovereign who, in the form of a judgment and/or punishment, sends down – or better, emanates – a form of miasmatic life that is indissociable from decay, decomposition, and death. What is noteworthy about the pre-modern concept of plague and pestilence is not only its blurring of biology and theology, but the profound lability that the concepts of plague and pestilence have. In the chronicles of the Black Death, plague seems to be at once a separate, quasi-vitalized ‘thing’ and yet something that spreads in the air, in a person’s breath, on their clothes and belongings, even in the glances between people. As one early chronicler notes, ‘one infected man could carry the poison to others, and infect people and places with the disease by look alone’.[17]

It is tempting to understand the Medieval hermeneutics of plague and pestilence as Neoplatonic – a supernatural force emanating from a divine centre. However this would require that we understand the relation between

---

[16] *Revelations* 15-16.

[17] See the chronicle of Gabriele de Mussis, translated and collected in *The Black Death*, ed. Rosemary Horrox (Manchester: Manchester University Press, 1994).

Creator and creatures as pathological, a divine sovereign that emanates itself through a miasmatic diffusion of decay. But what is being emanated here is not creation itself but rather its opposite, a kind of de-creation that occupies the underside of what Aristotle called 'passing away' (disease, decay, decomposition).[18] This strange type of life, that seems to emanate from a Neoplatonic One and diffuse itself throughout creaturely life, cannot be understood without taking into account another element. As varied as the Medieval accounts of plague and pestilence are, one of the common motifs, along with the angry God, is that of plague and pestilence as a divine weapon. The divine sovereign doesn't simply pass judgment; the sovereign weaponizes life – the pathological life of 'plagues' – and turns it against the earthly life of the creature, which is itself a product of the divine will.

Arguably this motif has its roots in antiquity: in Hesiod, for instance, we see how Zeus sends the 'gift' of plague-ridden Pandora to Prometheus as a form of retribution; likewise *The Illiad* opens with an angry Apollo sending down 'arrows' of plague upon the armies of men for their disrespect towards the gods. There are earthly instances of this as well. An oft-mentioned example in this regard is the Medieval practice of catapulting corpses. The primal scene in this regard is the fourteenth-century Italian trading post at Caffa, on the northern border of the Black Sea. Ongoing skirmishes between Italian merchants and Muslim locals led, in one instance, to the catapulting of plague-ridden corpses by the latter, over the fortress walls of the former.[19]

---

[18] The motif of decay has been picked up most recently by Reza Negarestani, who discusses 'decay as a building process'. In a seminar given at Goldsmiths College, Negarestani adopts two approaches to understanding the concept of decay – that of mathematics (derived from Scholasticism as it developed at Oxford) and that of architecture. There is much to expand upon here, particularly in the relation between architecture and resurrection. The ruin may be one conceptual mediation between them.

All of this is to suggest that the political theology of pestilence is not an issue of shutting-down or 'walling'. It is, certainly, that, but only to an extent. For the pervasive, diffuse, and circulatory quality of pestilence – this 'thing' or 'event' that is at once a divine emanation and yet a source of social and political chaos – raises a more complex problem for sovereign power: *how to control the pervasiveness of pestilence without losing control of the pervasiveness of people*.

But it is not clear in the accounts of chroniclers, or in the texts of Boccaccio, Chaucer, or Langland, if pestilence is that which causes social and political disorder, or if pestilence *is* continuous with this affective fantasy of total chaos. So we have a strange situation in which pestilence, itself supernaturally caused by a divine, primary sovereign power, then elicits a host of exceptional measures by secondary, earth-bound sovereign actors, in order to ward off the pending and pervasive chaos that pestilence occasions – which itself emanates from the primary, divine sovereignty – the *primum mobile* of pestilence, as it were.

---

[19] Here is De Mussis' account, which is thought by most historians to be second-hand: 'The dying Tartars, stunned and stupefied by the immensity of the disaster brought about by the disease, and realizing that they had no hope of escape, lost interest in the siege. But they ordered corpses to be placed in catapults and lobbed into the city in the hope that the intolerable stench would kill everyone inside [...] And soon the rotting corpses tainted the air and poisoned the water supply, and the stench was so overwhelming that hardly one in several thousand was in a position to flee the remains of the Tartar army. No one knew, or could discover, a means of defense'. In *The Black Death*, 17.

4. NEKROS

However, it should not be forgotten that the weaponized plague always targets a body or bodies. And what, indeed, is the target of the living weapon, if not the living target – that is, the corpse?

The concept of *nekros* has two significant meanings in classical culture. On the one hand, *nekros* is the corpse or the dead body. In the *Odyssey*, for instance, when Odysseus organizes the funeral rites for one of his companions, it is the *nekros* that is burned at the grave site: 'Once we'd burned the dead man (*nekros*) and the dead man's (*nekrou*) armour,/ heaping his grave-mound, hauling a stone that coped it well,/we planted his balanced oar aloft to crown his tomb.'[20] Certainly *nekros* names the singularity of the departed life, or of life recently departed from the body, leaving behind a corpse. But this corpse retains something residual of that life, insofar as both the corpse and its armor are together set upon the grave. We might even say that *nekros* not only names the 'dead man', but also the thingness of the corpse. In a sense *nekros* oscillates between the body-minus-life and the thingness of the corpse, the latter approaching the domain of the purely non-living (e.g., the armor as the non-living body).

However the *Odyssey* also contains another, more significant usage of *nekros*. This comes in the well-known passages recounting Odysseus' journey to the underworld. In this scene Odysseus first performs a sacrificial rite that calls to the dead, who then emerge from the underworld in a kind of slow-motion swarming:

> And once my vows and prayers had invoked the nations of the dead (*ethnea nekrôn*), I took the victims, over the trench I

---

[20] *The Odyssey*, trans. Robert Fagles (New York: Penguin), XII.13-15.

> cut their throats and the dark blood flowed in – and up out of Erebus they came, flocking toward me now, the ghosts of the dead and gone (*nekuôn kataethnêôtôn*)[21]

Here *nekros* no longer names the corpse, nor even the thingness of the corpse. Instead, *nekros* names something alive, or at least vitalized – but in a way fundamentally different from the life of *zoê*. *Nekros* as the corpse presumes a reliable boundary between life and death, whereas *nekros* as 'the dead' are characterized by an ambivalent vitalism. These dead souls are detained souls, they are immaterial yet non-transcendent, a life that at once continues to live on but that lives on in a kind of interminable, vacuous, immortality. *Nekros* is thus not the corpse but rather 'the dead', or the existence of a life-after-life.

But what, if anything, 'lives on' after life? Paul provides what would become a center of dispute in later theological debates over resurrection. The mortal body, like all living things, displays an infusion of life-spirit as well as processes of growth. 'But God gives it a body as he has determined, and to each kind of seed he gives its own body [...] So also is the resurrection of the dead. The body that is sown is perishable, it is raised imperishable [...] It is sown a natural body: it is raised a spiritual body.'[22] The organicist motif of resurrection is that of a seed that is sown in the earth and that grows and is animated (or re-animated) into a new body, the latter being both the resurrection of the person as well as that of the community of the *corpus mysticum*.

There is also a great deal of ambiguity in the Pauline formula. Patristic thinkers differed on what kind of life-after-life resurrection was, and how such a supernatural form of life was to take place.[23] One set of debates centres around the problem of the temporality of resurrection. If the living, mortal, earthbound body was susceptible to the processes of growth and decay, then in what material state would the body be resurrected? What kind of life returns? Would the resurrected body – the life-after-life – live in a state of perpetual stasis (as a kind of 'living statue'), or does it still undergo transformations, either in the form of higher perfections, or in terms of a beatific hypergrowth? The so-called material continuity debates among Patristic thinkers not only highlights the problem of time in relation to life and after-life, but it points to a problem that cuts across the theological and political domains (for instance, when Paul lays out the basic anatomy of the *corpus mysticum* as constituted both by unity and by participation).

---

[21] Ibid., XI.38-42.

[22] I Corinthians 15.38, 42, 44, New International Version.

Resurrection could be resurrection of the body, the soul, or more generally of 'the dead'. But even theories of the resurrection of the soul – as one finds in Origen's notion of a 'spiritual body' – still maintain the minimal necessity of a body-in-flux. The problems of material continuity are also linked to spatial and topological problems concerning the material process by which the formless body of decay and putrefaction is re-assembled and re-vitalized. The mere return of material particles does not constitute resurrection, for those particles must be either ensouled, renewed, or in some way cast anew. And here the almost absurdist debates concerning 'chain consumption' come into the foreground. If the corpse undergoes decay and decomposition into so many particles and non-living matter, if the corpse is devoured by worms and beasts, and those beasts devoured by man, how can the parts or particles of the body be re-assembled? (One can imagine a solution to this problem offered by Jarry's Ubu ...). One partial resolution, offered by Tertullian, was to shift emphasis from the matter to the form of the resurrected body, so that continuity could exist through change. Cannibalism thus does not negate continuity, and the living dead can also be the eaten dead.

---

[23] The most sophisticated account of such debates remains Caroline Walker Bynum's study *The Resurrection of the Body in Western Christianity, 200-1336* (New York: Columbia University Press, 1995).

The theological debates over resurrection point to some basic dichotomies: should the organicist model of the growth and decay of the natural world (seeds, plants, animals) serve as the analogical model for resurrection, or are those processes precisely what resurrection aims to correct and to 'heal'? Such questions have to do, in effect, with the nature and the supernature of the after-life, or better, with the relation between life and a 'life-plus-something' that constitutes the early Medieval theology and later Scholastic onto-theology. Insofar as the after-life is related in some way – as analogy, as model, as perfection – to finite, mortal life, it obtains a certain familiarity that enables thinkers such as Origen to talk at length about growth and decay in a theological context. But insofar as the after-life is a supernatural phenomenon, a divine and sovereign action, it remains outside the scope of philosophical and even theological inquiry.

How can life – something that is presumably *lived* – be situated at such a point of inaccessibility? Discussing the role of the supernatural in the eighteenth-century gothic novel, literary critic S.L. Varnado suggests that the aesthetics of the gothic novel revolve around a confrontation with the divine as an experience of horror. Varnado uses the theological term 'numinous' to describe this experience, the limit-experience of ‘absolute otherness’. In gothic fictions, the numinous is ephemeral; it can either be revealed to have natural and rational causes (as in Radcliffe’s *The Mysteries of Udolpho*), or the supernatural can be affirmed, and its horror sublimated into an affirmation of faith (Walpole’s *The Castle of Otranto*) or a descent into damnation (Lewis’s *The Monk*).

The concept of the numinous is etymologically associative to the Kantian concept of *noumena*. Kant’s own re-affirmation of the split between *phenomena* (the world as it appears to the subject) and *noumena* (the inaccessible world-in-itself) tended to draw his analyses towards the former and away from the latter. Indeed, there is a sense in which Kant’s antinomies of pure reason – God, the universe, the soul – are pushed so far away from *phenomena* that they begin to occupy a space not that far from *noumena*.[24] And yet it is precisely this domain – the anonymous ‘there is’ – that has for so long remained a point of attraction for ontology.

Let us consider a conceptual portmanteau, comprising the gothic ‘numinous’ (the horror of the divine as absolute otherness) and Kantian *noumena* (the unhuman, anonymous ‘in itself’). In what sense is the *nekros*, as ‘the dead’, also a kind of *nouminous life*? A nouminous life would have to articulate a conceptual space that is neither that which is lived and outside of discourse (the gothic ‘numinous’), nor that which is purely reasoned and unlived (the Kantian antinomies). We could call this a ‘horror of life’ if such a phrase did not bring with it undue anthropomorphic and even existentialist connotations. Perhaps we can say that, if the life-after-life is a nouminous life, it is because it elicits a *noumenal* horror that is the horror of a life that indifferently 'lives on'.

---

[24] Kant, in the *Lectures on Philosophical Theology*, notes the following: ‘God knows all things as they are in themselves a priori and immediately through an intuitive understanding. For he is the being of all beings and every possibility has its ground in him. If we were to flatter ourselves so much as to claim that we know the modum noumenon, then we would have to be in community with God so as to participate immediately in the divine ideas [...] To expect this in the present life is the business of mystics and theosophists [...] Fundamentally Spinozism could just as well be called a great fanaticism as a form of atheism’ (trans. Allen Wood and Gertrude Clark, Cornell University Press, 1978, 86).

5. The Spirit of Biology

The relationship between theology and horror in the West invites a number of superficial comparisons: in the Eucharist there is both cannibalism and vampirism; in the Jewish and Christian apocalyptic traditions the realization of the City of God always entails resurrection of the dead; and in numerous instances the New Testament portrays the various demons and demonic possessions that elicit the healing powers of the Messiah. Indeed, considering the extent to which genre horror deals with the themes of death, resurrection, and the divine and demonic, one could argue that genre horror is a secular, cultural expression of theological concerns.

If we look more closely, however, we see that in many instances it is a concept of 'life' that mediates between theology and horror. We can even imagine our theologians carefully watching the classics of early twentieth-century horror film: the relation between the natural and the supernatural (Aquinas watching *The Cabinet of Dr. Caligari*); the distinction or non-distinction between human and beast (Augustine watching *The Wolf Man* or *Cat People*); the coherence or incoherence of the *corpus mysticum* (Paul watching *Revolt of the Zombies* or *I Bury the Living*); the problem of the afterlife (Dante watching the Italian silent film version of *L'Inferno*). But one need not imagine such scenarios, for many so-called art-horror films deal with such issues, from David Cronenberg's early 'tissue horror' films, to Ingmar Bergman's *Through a Glass Darkly*, to Dario Argento's now-complete 'Three Mothers' trilogy.

If both theology and horror deal with the concept of 'life', then what exactly is this 'life' that lies at the limits of the thinkable? Aristotle gives us one clue. In the *De anima* Aristotle explicitly thinks the question of life as an ontological question, through the concept of *psukhê*: 'It must be the case then that soul (*psukhê*) is substance as the form of a natural body which potentially has life, and since this substance is actuality, soul will be the actuality of such a body.'[25] There is, to borrow terms that Scholasticism would favor, an 'ensoulment' or animation that thus takes place in hylomorphism, a process through which life is literally formed (or in-formed ... and sometimes de-formed).

However Aristotle gives us a slightly different picture in the *De Generatione et Corruptione*. Here the central question is not about any principle of life, but rather about the problem of morphology. Aristotle asks, how are 'coming-to-be' and 'passing-away' different from alteration in general? Are growth and decay merely examples of the larger genre of change in itself? This in turn leads to a more fundamental question regarding the domain of the living: 'What is that which grows'?'[26]

Aristotle's approach is to distinguish between different modalities of change. There are, first, the processes of alteration, which are qualitative (one thinks of a tree sprouting branches or an animal growing fur – the tree or animal remains the same kind of tree or animal).

---

[25] Trans. Hugh Lawson-Tancred (New York: Penguin, 1986), II.1.412a, 157.

[26] Trans. Harold Joachim, in *The Basic Works of Aristotle*, ed. Richard McKeon (New York: Modern Library, 2001), I.5.321a.30, 489.

There are also the processes of coming-to-be and passing-away, which are substantial changes (as when one animal is eaten by another animal, the former undergoing modification in substance). Finally, there are the processes of growth and decay, which can involve changes in magnitude (growing larger or smaller).[27] Now, while the first two are general processes of change that occur in the living and non-living, Aristotle implies that growth and decay are exclusive to the domain of the living. Why is this? One of the reasons Aristotle provides is that growth and decay, though exclusive to the living, fundamentally have to do with changes across the substance of the living and non-living, changes that may be due to 'the accession of something, which is called food' and is said to be 'contrary to flesh', and that involves the 'transformation of this food into the same form as that of flesh'.[28]

To Aristotle's example of nutrition we might also include the processes of decay and decomposition, the reverse passage of *nekros* into non-living matter. Food for worms ... But might we also include another passage, that of *nekros* into the life-after-life? What sort of change would this be – alteration, coming-to-be/passing-away, or growth/decay? Would this constitute a kind of biology of spiritual transformation, or would it constitute the 'spirit of biology'?

What horror explicitly thinks, theology implicitly admits: a profound fissure at the heart of the concept of 'life'. Life is at once this or that particular instance of the living, but also that which is common to each and every instance of the living. Let us say that the former is 'the living', while the latter is 'Life' (capital L). If the living are particular manifestations of Life (or that-which-is-living), then Life in itself is never simply this or that instance of the living, but something like a principle of life (or that-by-which-the-living-is-living). This fissure between Life and the living is Aristotelian in origin, but the fissure only becomes apparent in particular instances – we see it in the Scholastic attempt to conceptualize 'spiritual creatures', we see it in the problem of the life-after-life of resurrection, and we also see it in natural philosophy and the attempts to account for teratological anomalies and aberrations.

---

[27] 'We must explain (i) wherein growth differs from coming-to-be and from alteration', and (ii) what is the process of growing and the process of diminishing in each and all of the things that grow and diminish' (Ibid., I.5.320a.9-12, 485).

[28] Ibid., I.5.321b.36-322a.1-3, 490.

However, the most instructive examples come from classical horror film, in particular the 'creature features' of film studios such as Universal or RKO. The proliferation of living contradictions in horror film constitutes our modern bestiary. Let us consider a hagiography of life in the relation between theology and horror. The living dead, the undead, the demon-beast, and the phantasm. Each of these are *repudiations* of life, but not their full negation. Life is repudiated in favor of an ambivalent and 'nouminous' after-life. Each also takes up a certain relation between life and the political, centered around a key concept that structures its own genre conventions. The table overleaf provides a brief summary.

	LIVING DEAD	UNDEAD	DEMON-BEAST	PHANTASM
Exemplar	The zombie	The vampire	Demonic possession; lycanthropy	The ghost, the specter
Allegory	Working class, the mob, mass	Aristocratic, Romanticism	Bourgeois, the therapeutic	Divine-religious, the spirit, the soul
Avatars	Multitude, contagion	Blood, rats, bats, mist	Beast, animal, monster, chimera	Mediums, portents, signs
Ontology	Flesh	Blood	Meat	Spirit

Tables such as this obviously have their limitations. But one thing to note is that in each case we have a form of life that at once repudiates 'life itself' for some form of after-life. Each of these figures are literally living contradictions. The zombie is the animated corpse, the vampire is the decadence of immortality, the demon is at once a supernatural being and a lowly beast, and the specter exists through materializations of its immateriality. And, in each case, the form of after-life works towards a concept of life that is itself constituted by a privation or a negation, a 'life-minus-something'; the basic Aristotelian (and Hippocratic) concepts of flesh, blood, meat, and spirit are paradoxically living but without life. In this sense, *horror expresses the logic of incommensurability between Life and the living.*

6. UNIVOCAL CREATURES

One of the peculiarities of Aristotle's *De anima* is that, while it opens with the stated aim of inquiring into the 'principle of life', it quickly bypasses this aim in favor of detailed analyses of the natural world, the senses, and the intellect. What ostensibly begins with an investigation into the ontology of *zoê* ends with a rather opaque meditation on *nous*. It is almost as if Aristotle discovers that the question of 'life' can only be ontological if it ceases to be a question of life-as-such. This has also coloured later glosses on the text, such as those by Averröes and Aquinas, whose commentaries are themselves characterized by this shift.[29]

In Book II, however, Aristotle makes some important distinctions. After having offered the concept of *psukhê* as the life-principle, Aristotle distinguishes between different types of *psukhê* – that is, that *psukhê* is itself manifested in a range of specific forms. As is well-known, Aristotle distinguishes between plants, animals, and humans, based on the manifestation of *psukhê* or the life-form that governs them. While plants are characterized by a nutritive *psukhê*, animals are characterized by a sensory and motile *psukhê*, and humans by a reasoning or intellective *psukhê*. This forms an ascending order, for whereas plants are governed by nutrition, they can neither move nor think. The same follows for animals, since they lack reason.

The Aristotelian distinction was, of course, surpassed by the growth of natural history and, later, the emergence of a separate field of biology. But while the modern life sciences have analyzed the domain of the living down to the smallest molecule, the Aristotelian concept of a 'life principle' remains contested terrain.[30] In particular, one issue left unresolved in the *De anima* has to do with the concept of *psukhê* itself. Is there one, univocal *psukhê* that cuts across different domains of the living? Does *psukhê* in effect emanate from its ideal center towards the multitude of individual life forms? Or is there a *psukhê* that is proper to each individual, constituting a kind of propriety to *psukhê*?

---

[29] Averröes' notion of the 'material Intellect', as well as the Thomist distinction between existence and essence, can be regarded as attempts to smooth over the transition in the *De anima* between the question of 'life' and the question of thought.

The Scholastic reception of Aristotle offers a number of responses, and, ironically, forms an important chapter in the philosophy of biology. However, before Aristotle's 'biological' works make their appearance in the twelfth century via Arabic translations, there were already attempts to indirectly think Life as a name of the divine. The creature, emblematic of the domain of the living, is always a symptom. It is an effect, a product – as Bonaventure would put it, a *vestigium* or 'footprint' of the divine. The world of the living is a *liber creaturae*. Life is precisely that which is symptomatic of the divine, though it is not of the divine itself.

But it is Aquinas who both synthesizes the various positions on the creature and emphasizes that the concept of the creature revolves around the relation between Creator and creature, supernatural and natural, light and mud. In his attempts to wed Aristotelianism with Christian doctrine, Aquinas offers a neat summary of what we might call the 'creaturely triad'. What is the relation between the creature and Creator, between the living and the divine Life that make the living possible? Aquinas first sets up a dichotomy between two approaches, that of *equivocity* and that of *univocity*. In the first, there is no relation between creature and Creator, and the divine remains forever outside the possibility of being thought. In the second – univocity – there is a relation of continuity between creature and Creation, such that, in extreme cases, the latter can be said to be co-existent with and immanent in the former. The problems with each, from Aquinas' position, are easy to see. While equivocity forecloses any possibility of thinking or experiencing the divine, univocity makes it too easy, in effect flattening the divine onto nature. As is well-known, the solution offered by Aquinas is that of *analogy*. Between no relation (equivocity) and pure relation (univocity), there is partial relation, or analogy. Thus the creature is analogous to the Creator, their difference articulated in the form of degrees of perfection ('proportion' and 'proportionality'). The creature is the life that is less-than-divine, the Creator is the life that is more-than-the-living.

---

[30] The differing positions of genetic determinism, biocomplexity, developmental systems biology, and the various branches of cognitive science today raise these questions.

Might we also then say that, for Aquinas, the living are analogously related to Life? Aristotle's question of 'life' and the life-principle cannot be asked of Life as such. It can only be asked of the living, of something 'beyond' the living or that forms the living. But then we would have to consider 'life' in general as a kind of negative concept, a concept that at once asserts its asking as it recedes into the background of this question.

This negative concept of life is ontologized along two axes. The first is predicated on ontological difference. It posits a distinction, as we noted previously, between 'Life' and 'the living'. The *De anima* posits *psukhê* as a general life-principle, but at the same time distinguishes it from particular instances of the living in plant, animal, and human life. Everything hinges on the relation between Life and the living. In the period of high Scholasticism, the spectrum of creation, from monotheism to pantheism, from orthodoxy to heresy, illustrates the way in which the question of Life is never far from the question of the nature of the divine. In this sense the *De anima* is ontologically prior to texts such as *De Partibus Animalium* and *Historia Animalium*.

The non-concept of life is also aligned on a second axis, on which it is predicated on a distinction between a 'principle of life' and its corresponding 'boundaries of articulation' (this is its essence and existence, substance and accident). The principle of life may vary quite widely, from *psukhê* to a theological soul, to modern mechanism and/or 'vital spirit', to contemporary concepts of molecule, gene, and information. But it always makes possible one or more boundary relations that, when applied to the domain of the living, re-affirm the principle of life as essence. Such boundaries include, first and foremost, that between the living and the non-living. Secondary ones include the division between the organic and inorganic, and between human and animal.

7. Pathological Immanence

Arguably, the modern concept that has done the most to steer the question of life away from ontology has been that of the organism. Only when the relation between Life and the living can be encapsulated in the architecture of the organism, can the question of life emerge from its Scholastic hiding place into an epistemologically-rooted 'life science'.

But even in the life sciences there are innumerable instances of life-beyond-life, instances of 'the living' that turn back upon the hidden ontological question of Life.

For example, the emergence of a science of pathology – what Foucault, discussing pathological anatomy in the early nineteenth century, describes as the study of 'pathological life' – already points to the complicated way in which the question of *what* life is quickly folds onto the notion *that* life is. Foucault identifies several aspects to pathology – is it the study of the disease-in-itself, the disease as it is manifested in the patient, or the disease within a set of environmental conditions? Pathological anatomy signals an innovation because it not only posits that decay and decomposition are themselves processes of life, but that they exhibit characteristics that make them more than simply the inverse of growth, development, or the healthy state.

With the emergence of modern germ theory (Koch, Pasteur), the concept of immunity (Metchnikoff), and an epidemiology driven by political economy (Snow's cholera maps of London), the question becomes even more dense: not only are there distinct processes of after-life (decay, decomposition, putrefaction), but these are abetted by a host of life-forms that themselves resist easy classification within biology.[31] The concept of pathology is an after-life, in so far as it asks us to think Aristotle's distinction between growth and decay, coming-to-be and passing-away, in a single thought. Today, the study of pathology is often divided along sub-disciplinary lines that betray interesting assumptions: while virologists bracket the roles of environment and transmission, focusing on the pathogenic organism, epidemiologists black-box the pathogenic organism, emphasizing environment and a statistical approach that is biopolitically tied to public health.

---

31. For example, in modern debates over whether viruses are living. For a perceptive overview, see Lynn Margulis' book *Symbiotic Planet* (New York: Basic Books, 1998).

This last dichotomy is instructive, for it suggests to us several forms of after-life. As an organism, as a member of 'the living', the pathogenic organism (viruses, bacteria, fungi) can be situated broadly within the post-Darwinian *liber creaturae*. But, as we know, it is the very nature of such organisms to pass between life forms – to pass through, to pass between, and even, in cases of genetic mutation, to pass beyond. The means by which this is achieved are through processes that innately question the autonomy of the living organism – infection, transfection, parasitism, symbiosis. This in turn opens onto another, quite different form of after-life, one where the locality of 'the living' tends to become unlocalized, diffuse, distributed, and even invisible, tending towards an abstract domain in which 'the living' comes to overlap with 'Life'.

This is precisely the terrain explored by Deleuze, and the point of reference here is the Scholastic concept of the creature. *A setting of the creaturely life within an ontology of immanence* – perhaps this is the tension at the heart of Deleuze's own, peculiar form of vitalism. Deleuze's emphasis on the nonorganic life that altogether bypasses biological categorisation is often coupled with an equal emphasis on that which is alive, and not simply on that which exists. Though Deleuze, in his own writings and with Guattari, does make frequent references to the history of biology (e.g. the Cuvier-Geoffroy debate, Jacob and genetics, animal ethology), it is really in the context of Scholasticism that this type of Deleuzian biophilosophy can be identified.

In his lectures at Vincennes, Deleuze will often re-cast the Scholastic triad of analogy-equivocity-univocity in terms of another triad, that of transcendence-emanence-immanence. While Deleuze's admiration for Spinoza is well-known, it is

Duns Scotus who plays a pivotal role in the passage between the Neoplatonic emphasis on emanation and 'participation', and Spinoza's assertion of immanence, encapsulated in his famous phrase *Deus sive natura* ('God or nature').[32] The very problem of creation, and of the relation between Creator and creature, must presuppose a relation of continuity, even though a 'formal objective distinction' can still be made between the two: 'In the concept of a creature, however, no notion or species will be found to represent something proper to God which is wholly different in nature from anything pertaining to a creature.'[33] For Duns Scotus (in the 'strong' reading via Deleuze), nothing can be thought through the creature which is not univocally thought of the divine; the natural always implicates within itself the supernatural, life the after-life.

For Deleuze, the central ontological issue is thus not that of transcendence *vs* immanence, but rather of a different tension: that between *emanence* and immanence. The former produces immanent effects, but such effects emanate from a source that remains above and beyond those effects; emanence of effects implies an eminence of cause. Not surprisingly, Deleuze favors immanence, in which the effect is immanent in the cause. Deleuze expands the term 'expression', borrowed from Spinoza, to describe this creaturely immanence, essentially flattening out the

---

[32] Scotus, in the *Opus oxoniense*, notes that 'a species which can be multiplied in more than one individual, is not of itself determined to any certain number of individuals but is compatible with an infinity of individuals. This is evident in the case of all perishable species. Therefore, if the perfection of necessary existence can be multiplied in more than one individual, it is not of itself restricted to any certain number, but is compatible with infinity (trans. Allen Wolter, in *Duns Scotus: Philosophical Writings*, Hackett, 1987, I., dist.II, q.iii, 88).

[33] Ibid., I, dist. III, q.i, 29.

'divisions of nature' first formalized by Eriugena into a single, univocal, immanent expression: 'In the limit Nature as a whole is a single Animal in which only the relations between the parts vary.'[34]

If this notion of expressive immanence is, as Badiou notes, a 'vitalist ontology', is it vitalist because of what it says about 'Life' or for what it says about 'the living'? What, indeed, does vitalism come to mean in Deleuze's biophilosophy, if not a kind of subtractive vitalism, one that posits a creature-without-creation, an emanation-without-center, a decay that is growth, and a collapsing of 'Life' and 'the living', a distinction that structures both the Aristotelian and Scholastic concepts of life? If pathology broadly names one kind of life-after-life (growth-in-decay, coming-to-be in passing-away), a pathological immanence would name one of the central – unresolved – problematics of Deleuzian vitalism: that of the relation between 'life' and 'immanence'. If the former presumes some level of dynamic change (even if that change occurs immanently), the latter requires the existence of a fully actual, non-dynamic diffusion, enmeshing, or blanketing. The limit-point, the pathological turn, is at that point where immanence becomes so absolute that is becomes ambient and pervasive, itself receding into a zone of non-life.

8. Life as Non-Being

What is striking about many of the attempts to ontologize life is the way in which 'life' becomes an always-receding horizon. If we accept the Aristotelian distinction between Life and the living as structuring the philosophy of life in the West, then it would seem that Life is always receding behind the living. This is the limit of natural philosophy, beyond which one must have recourse to either natural theology or what Kant calls onto-theology, the system of knowledge of the 'being-of-all-beings'.

---

[34] Gilles Deleuze, *Expressionism in Philosophy: Spinoza*, trans. Martin Joughin (New York: Zone, 1990), 278.

But, in the tradition of Aristotelian natural philosophy, Life is not simply the absent center to every instance of the living. The relation between Life and the living is that, while the former conceptually guarantees the latter, in itself it is never available to thought. This, however, does not mean that Life is a concept of negation because it is privative, for its lack of 'thisness' is precisely what exceeds any particular instance of the living. If Life has a negative value, then, it is because of its superlative nature, because it exceeds any instance of the living. Any critique of life would have to begin from this presupposition of the superlative nature of Life. Life is 'nothing' precisely because it is never some thing.

In this sense, philosophical thinking about life borrows heavily from the tradition of mystical theology – and in particular from the tradition of negative theology. Before Anselm offers his famous ontological proof for the existence of God (God as 'that beyond which nothing greater can be thought'), the ninth-century Irish philosopher John Scottus Eriugena provides one of the most elaborate theories of the divine as 'nothing' (*nihil*). Eriugena's *Periphyseon* is deeply influenced by the apophatic approach of the Pseudo-Dionysius. But the *Periphyseon* applies a dialectical rigor not found in the latter's works. In Book III, Eriugena puts forth a notion of the 'divine darkness', in which the divine is *nihil* precisely because of its superlative nature: 'For everything that is understood and sensed is nothing else but the apparition of what is not apparent, the manifestation of the hidden, the affirmation of the negated, the comprehension of the incomprehensible [...]'[35]

To what extent can we say that Life is *nihil* in this sense? Once the ontological difference between 'Life' and 'the living' is collapsed, life subtracts from itself any possibility of an affirmation. What remains is a kind of negative theology, or better, a negative theo-zoology, whereby life always displays some relation to the negation of life. Hence the after-life is not about the dichotomy between life and death, but about a more fundamental relation – that between Life and Being.

One problem has to do with what happens once the concept of 'Life' detaches itself from 'the living'. This is a problem implicit in the *De anima*, where the concept of *psukhê* is sometimes a life-principle, and sometimes a stand-in for the being of form itself. In a modern context, process philosophy (Bergson, Whitehead) and process theology (Chardin, Steiner) likewise reach a zone in which 'Life' becomes convertible with Being – even if the name of Life is process or becoming.

For many, however, all of this is a false problem. The opening sections of *Being and Time* provide what is perhaps the clearest statement on this point. There Heidegger effectively glosses over the fields of anthropology, psychology, and biology as fields which must presume being in order to begin their inquiries about man, mind, and organism. While each of these fields, according to Heidegger, deals in some way with Life, none of them are capable of posing the question of Life as an ontological question:

---

[35] Book III, 633A, from Iohannis Scotti Erivgenae, *Periphyseon* (*De Divisione Naturae*), *Liber Tertius*, ed. and trans. I.P. Sheldon-Williams with the collaboration of Ludwig Bieler (Dublin Institute for Advanced Studies, 1981).

> [...] in any serious and scientifically minded 'philosophy of life' (this expression says about as much as the 'botany of plants') there lies an inexplicit tendency toward understanding the being of Da-sein. What strikes us first of all in such a philosophy (and this is its fundamental lack) is that 'life' itself as a kind of being does not become a problem ontologically.[36]

This 'missing ontological foundation' is itself what grounds these fields. The question *that* Life is, is displaced by the question of *what* Life is – or, more accurately, what the domain of the living is. The anthropological category of man, the psychological category of mind, and a general biology of the organism all presume a Being of Life. Where Heidegger leaves off, however, is at the question of whether Life is a species of Being, or whether the ontology of Life in effect transforms Life into Being. His last words on the topic are at once suggestive and opaque: 'Life has its own kind of being, but it is essentially accessible only in Da-sein.'[37]

One point of entry is to think about non-Life (a non-Life that is not Death), and by extension, non-Being (a non-Being that is not Nothing). Put another way, the challenge would be to think the relation between Life and Being as mediated by negation. This is, to be sure, an ancient problem, one posed by the presocratics, in the attempt to secure a conceptually-sound concept of the One or the Many. At its root is the problem – really, the profound ambivalence towards – the concept of non-Being. As Levinas notes, in a language not too far removed from Eriugena:

---

[36] *Being and Time*, trans. Joan Stambaugh (Albany: State University of New York Press, 1996), §10, 43-44.

[37] Ibid., 46.

> When the forms of things are dissolved in the night, the darkness of the night, which is neither an object nor the quality of an object, invades like a presence [...] But this nothing is not that of pure nothingness. There is no longer this or that; there is not 'something'. But this universal absence is in turn a presence, an absolutely unavoidable presence [...] There is is an impersonal form, like in it rains, or it is warm.[38]

Thus the problem of non-Being is not simply that of a fear of nothingness or of the vacuum. Rather, it is the quite gothic fear of a something whose thingness is under question. 'This impersonal, anonymous, yet indistinguishable consummation' of being, which murmurs in the depths of nothingness itself we shall designate by the term there is [...] The rustling of the there is [...] is horror.'[39] The pinnacle of this type of horror – really a kind of concept-horror – is the evisceration of all noological interiority: 'horror turns the subjectivity of the subject, his particularity qua entity, inside out.'[40]

What is the 'there is' of Life? Is the concept of Life already a 'there is', and therefore already enveloped in the gothic horror of absolute otherness and pervasive anonymity? If 'Life', as opposed to 'the living', is always receding into the anonymous 'there is', does this then mean that Life is really Life-without-Being?

[40] Ibid., 33.

9. ANONYMOUS HORROR

Granted, there is a certain absurdity in asking about the non-being of Life; one might as well inquire into non-existent creatures ... which is, of course, precisely what the domain of supernatural horror does. Horror film is replete with examples of the horror of the 'there is ... ' The titles of such films are telling: *The Being*, *The Creature, The Entity, It's Alive!, It Lives Again*, *Monster Zero, The Stuff, Them!, The Thing*, and so on. In these films, the site of horror is not simply that of a physically threatening monster, for at least these can be given names (Dracula, Frankenstein's monster, Wolf-Man), and thereby included within the sphere of moral and theological law. This also means they can be destroyed. But what of the creature that cannot be named, or that is named in its unnamability? The unnamable creature is also the unthinkable creature. This would be the B-horror version of Beckett's *L'innomable*. In some cases the unnamable creature is without form, the intrusion of a raging, inverted hylomorphism. Cold War films such as *The Blob* and *Caltiki the Immortal Monster* exist in a state of oozing, abject, borderlessness. In other cases the unnamable creature is without matter, existing as pure (demonic) spirit, an inverted theophany. In *Fiend Without A Face*, human beings are besieged by immaterial, brainstem-like entities, suggesting telepathy as a form of contagion.[41]

These films represent a subtle subversion of the classic creature-feature by shifting the criteria by which a monster is made. Whereas the creature-feature films define the monster as an aberration (and abomination) of nature, the unnamable creature is an aberration of thought.

---

[41] In postmodernity this tradition is extended in films such as Mario Bava's *Planet of the Vampires*, Cronenberg's *Scanners* and Kiyoshi Kurosawa's *Cure*.

The classical creature-features still retain an element of familiarity, despite the impure mixture of categories (plant + human) or differences in scale (giant reptiles, ants, leeches, etc.). Films featuring unnamable creatures, by contrast, contextualize the monster in terms of ontology (form-without-matter, matter-without-form) or in terms of onto-theology (the spiritual abject, the oozing abstraction). They point towards a form of life-after-life that highlights conceptual aberrations.

Let us pause for a moment and gather together our propositions concerning this concept-horror, or, granting ourselves some poetic license, what we can also refer to as the 'teratological noosphere':

- The question of an ontology of life is traditionally predicated on a fundamental distinction between Life and the living, or, between that-by-which-the-living-is-living and that-which-is-living.
- This distinction is deployed along two axes: One which requires a 'principle-of-life' to structure all manifestations of the living, and another in which the living is in turn structured according to various 'boundaries of articulation'.
- In the context of Scholasticism, the ontology of life continually oscillates between a natural philosophy of creatures and an onto-theology of the divine nature.
- The structure of the concept of life is most often that of negative theology.

Each of these propositions structures the basic way in which 'life' as a concept is thought as such. Each of these also contain one or more fissures, one or more 'heretical' strands of thinking. To this we can offer another proposition:

- In its traditional onto-theological formulations, Life is what is denied of Being. While the latter is the domain of the transcendent, the eternal, the infinite, the spiritual, and the fully actual, the former is subtracted from this – the immanent, the temporal, the finite, the material, and the virtual.

Life therefore bears some minimal relation to non-Being. But this can take several forms. The non-Being of Life can be situated either 'above' or 'below' the scale of the human – on the one hand there is the strata of Thomist 'spiritual creatures' or the strata of Aristotelian creaturely life, while on the other hand there is the strata of demonic multitudes or the strata of subhuman plague and pestilence. This non-anthropomorphic and even misanthropic quality of Life sustains these strata with a certain inaccessibility. Even as Life, in conditioning the living, is able to assert its self-evident character, it also puts forth its noumenal qualities. Kant's statements concerning the teleology of the natural world would have to be qualified: *it is because Life is noumenal that it is teleological.* But this then means that the 'ends' of Life are also 'anonymous'.

Any question of the possibility of an ontology of life would have to consider 'life' as a particular intersection between a biology of a non-conceptual life itself and an onto-theology of transcendence, emanence, and immanence. The problem is that the concept of Life has remained tenaciously non-conceptual, even as it continues to function in a conceptual, even ontological way in contemporary scientific fields such as network science, swarm intelligence, and biocomplexity. The issue is not that Life cannot think its own foundationalism, its own decision. Indeed, this is arguably what post-Darwinian biology obsesses over. Rather, the issue is that Life as a concept must always presume a further question concerning Being. The infamous question 'What is Life?' appears to be always superseded by the question of 'What is Being?' And yet the very idea of Life-without-Being would seem to be an absurdity for philosophy – though, as we've seen, not for horror.

Weird; Hauntological: Versus and/or and and/or or?

China Miéville

0. Prologue: the Tentacular Novum

Taking for granted, as we do, its ubiquitous cultural debris, it is easy to forget just how radical the Weird was at the time of its convulsive birth.[1] Its break with previous fantastics is vividly clear in its teratology, which renounces all folkloric or traditional antecedents. The monsters of high Weird are indescribable and formless *as well as being* and/or *although they are* and/or *in so far as they are* described with an excess of specificity, an accursed share of impossible somatic precision; and their constituent bodyparts are disproportionately insectile/cephalopodic, without mythic resonance. The spread of the tentacle – a limb-type with no Gothic or traditional precedents (in 'Western' aesthetics) – from a situation of near total absence in Euro-American teratoculture up to the nineteenth century, to one of being the default monstrous appendage of today, signals the epochal shift to a Weird culture.[2]

The 'Lovecraft Event', as Ben Noys invaluably understands it,[3] is unquestionably the centre of gravity of this revolutionary moment; its defining text, Lovecraft's 'The Call of Cthulhu', published in 1928 in *Weird Tales*. However, Lovecraft's is certainly not the only *haute* Weird. A good case can be made, for example, that William Hope Hodgson, though considerably less influential than Lovecraft, is as, or even more, remarkable a Weird visionary; and that 1928 can be considered the Weird tentacle's coming of age, Cthulhu ('monster […] with an octopus-like head') a twenty-first birthday iteration of the giant 'devil-fish' – octopus – first born to our sight squatting malevolently on a wreck in Hodgson's *The Boats of the 'Glen Carrig'*, in 1907.[4]

There are, of course, honoured precursors: French writers were early and acute sufferers from Montfort's Syndrome, an obsessive fascination with the cephalopodic.[5] In short order, the two key figures in the French pre-Weird tentacular, Jules Verne and Victor Hugo, produced works –

---

[1] S.T. Joshi's periodisation of the golden age of Weird as 1880-1940 is persuasive (S.T. Joshi, *The Weird Tale*, Austin: University of Texas Press, 1990).

[2] I have argued this elsewhere: 'Introduction' to H.P. Lovecraft, *At the Mountains of Madness* (NY: Random House, 2005); presentation at the 'Weird Realism: Lovecraft and Theory' event, London, Goldsmiths, 26 April 2007; 'Weird Fiction', in Mark Bould and Sherryl Vint (eds.), *Routledge Companion to Science Fiction* (London: Routledge, 2008 [forthcoming]).

[3] In his contribution to the 'Weird Realism' event in 2007 (see previous note).

[4] William Hope Hodgson, *The House on the Borderland, and Other Novels* (London: Gollancz, 2002), 28-29.

[5] Named by Reza Negarestani for Pierre Dénys de Montfort (1766–1820), pioneering and dissident French malacologist, author of, among others, the multi-volume *Histoire Naturelle Générale et Particulière des Mollusques* (6 volumes [1-4 only by de Montfort] Paris: F. Dufart, 1801-5), which took seriously the existence of the 'kraken octopus' and 'colossal octopus', and included still-iconic illustrations.

Verne in *20,000 Leagues Under the Sea* (1869) and Hugo in *The Toilers of the Sea* (1866) – which include extraordinary descriptions of monster cephalopods. These texts, while indispensable to the development of the Weird, remain in important respects *pre*-Weird not only temporally but thematically, representing contrasting *oppositions* to the still-unborn tradition, to varying degrees prefigurations of the Weird *and* attempts pre-emptively to de-Weird it.

Verne reveals his giant squid[6] at the end of a character's careful itemisation of its qualities, qualities which *he* can see, but which we for several paragraphs suppose him to be remembering from descriptions ('Did it not measure about six metres? […] was its head not crowned with eight tentacles…? [...] were its eyes not extremely prominent […] ?').[7] The animal thus appears pre-mediated by human understanding, at the end of a long section detailing the history of architeuthology, so that its monstrousness, though certainly not denied, is already defined by human categorisation. Frisson notwithstanding, the Weird, usually implacably Real in Lacanian terms, is preincorporated into the symbolic system.

When he sees it, the narrator Arronax relays the sight with a laborious itemised description interrupted by pedantic asides ('Its eight arms, or rather legs, were […] implanted on its head, thus giving these animals the name of cephalopods') and questionable exactitude that can only undermine the 'cosmic awe'[8] which typifies the Weird ('We could distinctly see the 250 suckers in the form of hemispherical capsules […]'). Arronax carefully uses '*bras*' then '*pieds*' to describe the limbs, rather than his assistant's '*tentacules*': scientism rejects the tentacle. 'I did not want to waste the opportunity of closely studying such a specimen of cephalopod', Arronax tells us. 'I *overcame the horror* its appearance caused me, picked up a pencil, and began to draw it.'[9] Verne mounts a pre-emptive rearguard defence of a bourgeois 'scientific rationality', depicting it as stronger than this new bad-numinous.

---

[6] In fact the animal is, fittingly, slightly evasive of precise taxonomy: it is described as a '*poulpe*', usually translated 'octopus', and as '*calmar*', 'squid'. Though it seems to resemble the latter more than the former, with eight limbs it is lacking the squid's two longer hunting arms. It has also been translated into English as an 'immense cuttlefish', 'devil-fish', and indeed as a 'poulp'.

[7] All quotations from Jules Verne, *20,000 Leagues Under the Sea*, translated by William Butcher (Oxford: Oxford University Press, 1998, revised 2001. Available at: <http://home.netvigator.com/~wbutcher/books/20t.htm>).

Arronax describes his own description as 'too pallid', and says that only 'the author of *The Toilers of the Sea*' could do it justice. The reference is to the extraordinary passage in which Hugo's Gilliat is attacked by a '*pieuvre*' (Guernésiais for octopus), the greatest and strangest of the pre-Weird reveries on the tentacular, and favourite for the title *tout court*. The chapter is a visionary rumination on the horror of octopus-ness. The creature is described in a vomit of aghast and contradictory metaphors and similes: 'a rag of cloth', 'a rolled-up umbrella', 'disease shaped into a monstrosity', 'a wheel', 'a sleeve containing a closed fist', 'birdlime imbued with hate', 'a pneumatic machine' – and on and on.[10]

Though Hugo is far less cited than Verne as an influence on the fantastic genre-cluster with which Lovecraft is also associated, his passage is much closer to *haute* Weird. Hugo counterposes the octopus to the chimera, to underline the former's afolkloric monstrousness. He repeatedly stresses the octopus's taxonomic transgression: it has no claws, but deploys vacuum as a weapon; it eats and shits with the same orifice (supposedly); it swims and walks and crawls; it is – as he stresses with ecstatic Kristevan disgust at the octopus-as-abject – flaccid, gangrene-like, and, 'horrifyingly […] soft and yielding'.[11] The octopus is problematised ontology.

---

[8] What Lovecraft calls 'Cosmic alienage or "outsideness"' (H.P. Lovecraft, *Notes on Writing Weird Fiction*, 1937. Among many other locations, see: <http://www.geocities.com/soho/cafe/1131/14notesen.htm>).

[9] Verne, *20,000 Leagues Under the Sea* [emphasis added].

[10] Victor Hugo, *The Toilers of the Sea*, translated by James Hogarth (New York: Random House, 2002), 350-352.

Hugo is nowhere more Weird than in his admirably clear insistence that octopuses, 'killjoys of the contemplator', demand a *rethinking of philosophy*.[12] There are, nonetheless, what one might archly call 'countervailing tendencies' pulling the passage away from *haute* Weird (it should go without saying that this is genealogy not criticism).

Though distinguished from the chimera, the octopus is identified with the Medusa, demon, and, repeatedly, with the vampire, reacquainting it, if unstably, with 'traditional' teratology. The octopus is obsessively depicted as evil – indeed, such a 'perfection of evil' that its existence is a vector of heresies of a double god, a cosmic parity of good and evil.[13] Although, in a more subterreanean moment of French cephalopodia, Lautréamont deploys the octopoid to mock moralism, as when 'legions of winged squid[14] […] scud swiftly toward the cities of the humans, their mission to warn men to change their ways', a similar problematic is evident in *Maldoror* (1869). Lautréamont's

---

[12] Ibid., 354.

[13] Ibid., 355.

[14] '*poulpes*' – octopuses, properly.

God is confronted by Maldoror 'changed into an octopus, clamp[ing] eight monstrous tentacles about his body', the two now knowing they 'cannot vanquish each other'.[15] This Manichean tentacular is in sharp contrast with the monstrosities of *haute* Weird, which are impossible to translate into such terms – predatory and cosmically amoral, but not 'evil'. If they serve any morally heuristic purpose it is precisely to undermine any religiose good/evil binary.

Counterintuitively, it is also precisely Hugo's heady itemisation of the octopus's dreadfulness that pulls against its Weirdness. Hugo decries the devilfish as unthinkable with what is almost a sermon, that unfolds aghast, yes, but *without surprise*. Hugo's octopus lurks like a bad conscience, a horror that we *already know* we are inadequate to thinking. By contrast, whether one deems it successful, risible, both, or something else, Lovecraft's hysterical insistences that *nothing like this had ever been seen before*, that *nothing could possibly prepare anyone for such a sight*, when his Great Old Ones appear, is the narrative actualisation of the Weird-as-novum, unprecedented, Event.

In 1896, the other great early adopter of the tentacular, H.G. Wells, published the first and neglected *haute* Weird text (despite its author not generally being located in the sub-genre, perhaps because of the never-convincing Fabian camouflage draped over his bleak numinous). 'The Sea Raiders' tells of *Haploteuthis ferox*, a hitherto-unknown and aggressively predatory cephalopod which besieges the English coast, rising from deep waters to feed on boaters, and disappearing again.[16]

---

[15] The Comte de Lautréamont, *Maldoror & The Complete Works*, translated by Alexis Lykiard (Cambridge: Exact Change, 1994), 101, 103.

[16] <http://en.wikisource.org/wiki/The_Sea_Raiders>

There is no Vernian rejection of ‘tentacle’: the word and its derivations appearing twenty times in the short piece. There is no moralism – though horrifying, the monsters are predators, not devils. Above all, ‘this extraordinary raid from the deeper sea’ is unprecedented, unexpected, unexplained, unexplainable – it simply is. All that we who suffer this tentacular Event can hope is that they have returned ‘to the sunless depths of the middle seas, out of which they have so strangely and so mysteriously arisen.’

The three decades between the Verne/Hugo/Lautréamont moment and Wells’s saw the Franco-Prussian War and the Commune, the so-called ‘Long Depression’ of 1873-1896, the rise of ‘new unionism’, and the ‘new imperialism’ and murderous ‘scramble for Africa’.[17] Increasingly visible, especially in the last, the crisis tendencies of capitalism would ultimately lead to World War I (to the representation of which traditional bogeys were quite inadequate). It is the growing proximity of this total crisis – kata-culmination of modernity, ultimate rebuke to nostrums of bourgeois progress – that is expressed in the shift to the morally opaque tentacular and proto-Lovecraftian radical Weird of ‘The Sea Raiders’.

Like Wells and unlike Lovecraft, William Hope Hodgson was barometric enough to the incipient apocalypse to en-monster it *before* it exploded into the war that killed him. In a stunning letter describing the front, he refers to what he considered his masterpiece, *The Night Land*: ‘My God, what a Desolation! […] the Infernal Storm that seeps for ever, night and day, day and night, across that most atrocious Plain of Destruction. My God! Talk about a lost World – talk about the END of the World; talk about the "NightLand" – it is all here, not more than two hundred odd miles from where you sit infinitely remote.'[18] The Weird is here explicitly, in John Clute's magnificent formulation, 'pre-aftermath fiction'.[19]

---

[17] Simultaneous with the increase of its formlessness and historylessness, its efficacy as placeholder for the unrepresentable, the octopus’s somatic specificity – its spreading tentacles – also saw it increasingly deployed in satire as symbol for the ‘new imperialism’.

The Weird's unprecedented forms, and its insistence on a chaotic, amoral, anthropoperipheral universe, stresses the implacable alterity of its aesthetic and concerns. The Weird is irreducible. A Weird tentacle does not 'mean' the Phallus;[20] inevitably we will mean with it, of course, but fundamentally *it* does not 'mean' at all (perhaps Weird Pulp Modernism is the most Blanchotian of literature).

1. DEATHMATCH

The Weird, then, is starkly opposed to the hauntological. Hauntology, a category positing, presuming, implying a 'time out of joint',[21] a present stained with traces of the ghostly, the dead-but-unquiet, estranges reality in an almost precisely opposite fashion to the Weird: with a radicalised uncanny – 'something which is secretly familiar, which has undergone repression and then returned from it'[22] –

---

[22] Sigmund Freud, 'The Uncanny' (1919). <http://www-rohan.sdsu.edu/~amtower/uncanny.html>.

rather than a hallucinatory/nihilist novum. The Great Old Ones (Outer Monstrosities, in Hodgson's formulation)[23] neither haunt nor linger. The Weird is not the return of any repressed: though always described as ancient, and half-recalled by characters from spurious texts, this recruitment to invented cultural memory does not avail Weird monsters of Gothic's strategy of revenance, but back-projects their radical unremembered alterity into history, to en-Weird ontology itself.

Weird writers were explicit about their anti-Gothic sensibility: Blackwood's camper in 'The Willows' experiences 'no ordinary ghostly fear'; Lovecraft stresses that the 'true weird tale' is characterised by 'unexplainable dread of outer, unknown forces' rather than by 'bloody bones, or a sheeted form clanking chains according to rule'.[24] The Weird entities have waited in their catacombs, sunken cities and outer circles of space since aeons before humanity. If they remain it is from a pre-ancestral time. In its very unprecedentedness, paradoxically, Cthulhu is less a ghost than the arche-fossil-as-predator. The Weird is if anything ab-, not un-, canny.

This must be insisted upon for the heuristic edges of the Weird and the hauntological – and indeed of other fantastic categories – to stay sharp. Hence the importance of 'Geek Critique', which rebukes, say, Terry Eagleton when he blithely discusses the 'rash of books about vampires, werewolves, zombies and assorted mutants, as though a whole culture had fallen in love with the undead';[25] because whatever the merits of the rest of his argument, *only two of those figures are undead*, and *they are all different*. Teratological specificity demands attention. And, granting the controversial position that ghosts are teratological subjects, such specificities are nowhere more different and important than between Weird and hauntological.

Eagleton's sort of cavalier hand-waving is increasingly rare, at least when it comes to the ghostly. Compare Eagleton with Sasha Handley, who points out that 'to distinguish the particular meanings attached to ghosts' demands taxonomy, and that her object of study is not 'anonymous angelic or evil spirits' but 'spirit[s] appearing after death'.[26] Some years previously, however, two such perspicacious writers as Julia Briggs and Jack Sullivan as a matter of policy play fast and loose with categories of ghosthood. 'I am […] compromising', Sullivan says. 'All of these stories are apparitional, in one sense or another, and "ghost story" is as good a term as any.'[27] According to Briggs, 'the term "ghost story" […] can denote not only stories about ghosts, but […] spirits other than those of the dead […] To distinguish these from one another according to the exact shape adopted by the spirit would be an unrewarding exercise.'[28] I have argued, rather, that the ‘exact shape’ is of enormous importance.

[27] Jack Sullivan, *Elegant Nightmares: The English Ghost Story from Le Fanu to Blackwood* (Athens: Ohio University Press, 1978), 9. While praising the book in her invaluable bibliography on the supernatural, Jessica Amanda Salmonson takes Sullivan to task for the 'obscene impression that there were no women writers of ghost stories in England'. <http://www.violetbooks.com/bib-research.html>

[28] Julia Briggs, *Night Visitors: The Rise and Fall of the English Ghost Story* (London: Faber 1977), 12.

Briggs and Sullivan are wrong, but their error is not merely personal. While we may sympathise with S.T. Joshi in finding this use of the term ‘ghost story’ ‘irksome’, his deployment of a robust common sense against it – ‘To me “ghost story” can mean nothing but a story with a ghost in it’[29] – does not get at the nature of the problem. Key here is Briggs’s justification of her imprecision by claiming that the term ‘ghost story’ ‘is being employed with something of the latitude that characterizes its general usage’.[30] The imprecision is that of the culture, and it shifts.

A quarter-century before Briggs, ‘reasons of simplicity’ were sufficient for Penzoldt to ‘use the term “ghost story” also for tales of the supernatural that do not deal with a ghost’.[31] Mindful that there is nothing simple about such a decision, Briggs by contrast feels the need to justify her own position at some length: the looseness of usage is changing. A quarter-century after her, the new common sense has become that *ghostly* ghost stories are ‘a distinct literary form’,[32] and when Handley asserts her own position, precisely contrary to Briggs’s, almost as read but *not quite*, she takes a moment to argue it. Clearly the politics of ghostly specificity has shifted markedly, but has not banished all remnants of its countertendency – hauntology is haunted by a pre-hauntological taxonomic indeterminacy.

[29] Joshi, *Weird Tale*, 2.

[30] Briggs, *Night Visitors*, 12.

[31] Peter Penzoldt, *The Supernatural in Fiction* (London: Peter Nevill, 1952), 12 n.12.

[32] Srdjan Smajic, ‘The Trouble with Ghost-Seeing: Vision, Ideology, and Genre in the Victorian Ghost Story’, *ELH*, 70:4, Winter 2003, 1107-1136, at 1131.

At this point in history, describing as a 'ghost story' a piece about werewolves or vampires, let alone about Shub-Niggurath or similar, would likely be considered false advertising. But it was not always so. In the early twentieth century, the terato-taxonomic membrane least breached today, that between the Weird and the Hauntological, was more likely to be permeated than that between ghosts and 'traditional' monsters. The self-styled 'ghost stories' of the 1920s might feature, say, giant flesh-sucking slugs ('Negotium Perambulans' and 'And No Bird Sings', by E.F. Benson).

As Handley points out, a ghost meant to the eighteenth-century English just what it does to us now: a revenant, not some eldritch oozing tentacled thing. At some point after 1800, however, that distinct ghost-ness of the ghost ebbed – temporarily, as it turned out – until by 1910 Hodgson's *haute*-Weird adventurer Carnacki could without embarrassment be described as a 'Ghost Finder' in his battles with Hog-manifestations of 'million-mile-long clouds of monstrosity'.

It is not so much irony as a constitutive contradiction that it was a few years before that, in the mid-to-late nineteenth century, almost precisely in the middle of that trajectory of the de-ghosting ghost, that the key works of what is now vaunted as a *high* ghostly, an *echt* hauntologic, the 'tradition' of the English ghost story, appeared.

2. ANCESTRAL SPIRITS

The eighteenth-Century ghost was a revenant who tended to moralism and anti-Popish sniping, embodying as dread example lessons about virtue, justice, and so on.[33]

---

[33] Handley, *Visions*, 16-19.

In the early nineteenth century, the explicitly sectarian character of that moralism had waned, but the instructional nature of hauntings remained.

Cultural production expressed anxiety over the sclerotic arrogance of the Victorian era and its victims, as well as the dominant culture's ideological counterattack, the tendency to increased and cruder moralism. Non-mimetic art tends to express such frictions particularly vividly, and in the nineteenth century we can see the battle for the two souls of the ghost in the fictions of Dickens, versus those of the man he published,[34] Sheridan Le Fanu.

Dickens thinks nothing of jostling together, in 'A Christmas Carol', the ghost of a person, Jacob Marley, with those of various Christmases. To post-hauntological eyes this is a category-error, but Dickens is merely subordinating the specifics of the ghost to his extreme and mawkish extrapolation of the preceding epoch's tendency to morally 'mean' with spectrality. In neither 'The Haunted House' (1859) nor 'The Haunted Man' (1848) are the haunts revenants of the dead, but 'of my own innocence', or a doppelganger who performs a selective mnemectomy so the story can thumpingly moralise that it is important to remember wrong done to us 'that we may forgive it'. Dickens's ghosts are apotheoses of the instructional ghosts of the preceding century – out of time, rearguard in their sentimentality, themselves haunted by the future. They are not so much convincing, morally, as performatively flourished. These are not modern ghosts, but the last, already-dead walking dead of a dead epoch, bobbed about on sticks.

---

[34] Le Fanu's masterly 'Green Tea' appearing in *All the Year Round* in 1869.

Le Fanu's ghosts, by contrast, in their moral contingency, are intimations of disaster.[35] Even in his more seemingly traditional 'moral' stories, such as 'Mr Justice Harbottle' (1872), the nature of the spectral agents of revenge – their inhuman, de-subject-ed strangeness, and the repeated intimations that they, victims of injustice, are in hell ('pallid […] secretly suffering […] glittering eyes and teeth') makes sense according to no moral accounting. In the extraordinary 'Green Tea' (1869), the text's insinuations that Jennings's merciless torment at the hands of the abominable monkey spirit is in some way payback – that he is 'guilty', that he shows 'shame', though for what is unknown – read as morally obscene.

The blurring of the Weird with the ghostly is prefigured in the auditioning of animal spirits as avatars of the monstrous (before the Weird's demand to be considered cephalopod was clear), in the stark and amoral universe, in the protoplasmic formlessness of the dying vampire Carmilla (1872), in the autotelos of the monster (the monkey in 'Green Tea' just *is*). For these reasons it is tempting to agree with Sullivan that Le Fanu, rather than the more-usually-cited James, is the key revolutionary figure in the so-called 'traditional' ghost-story that we can now see was a – Weird-inflected – 'New Ghostly'.

However, while his fiction is if anything more vatic and perspicacious than James's (shades of Hodgson and Lovecraft), Le Fanu is a towering *interstitial* figure. The popular story of his death is so theoretically kitsch on this point that it could have been scripted by a cultural critic. Le Fanu was reputedly a martyr to a recurring nightmare about being crushed to death by the collapse of an old grand mansion. When discovered dead, a horrified look on his face, his doctor was said to have intoned: 'I feared this. That house fell on him at last.' The story is tenacious, which, in the face of the fact that it is almost certainly untrue,[36] bespeaks its cultural resonance. Le Fanu's problematic is the crisis and coming fall of the house of Victoriana (and of the particular colonial upheavals of fading Protestant Ascendancy), and as such foundational to what followed; but the present of which it is a vivid expression is the fringe of a past, rather than the start of a future. His fiction is of end and failure.

---

[35] Sullivan is excellent on this point, and I draw on him here extensively. *Elegant Nightmares*, 32-68.

The politics of sensory perception are important. Le Fanu, in his masterwork 'Green Tea', stresses the malevolent inhuman strangeness of the monkey, but also that it was *incorporeal*. This was, in ghost-story terms, not 'New Ghostly' but 'new traditionalism', uniting Le Fanu with Dickens and other pre-Weird, fabular-logic-wielding ghost-smiths. As Victorian ghosts grew more ostentatiously moralistic, they decorporealised. (In earlier centuries they had moralised *and* provided the thrills of physicality: they were often 'thought capable of moving material objects and of inflicting physical harm […] [and] those who were confronted by ghosts believed that they could inflict material damage by shooting or stabbing the spirit'.)[37]

Central in marking him out as the key figure in this peculiar period, later to be designated the birth of a ghost-nation, Le Fanu's disciple M.R. James's ghosts could be touched, and touch.

3. THE OLD NEW WEIRD GHOSTLY

James is regularly cited as a – or *the* – founder of the 'tradition' of English ghost stories. It is commonplace to then wryly point out that James's ghosts are in fact often not ghosts, but inhuman 'demons' of one sort or another.[38] Lovecraft stressed that James had 'invent[ed] a new type of ghost', not 'pale and stately, and apprehended chiefly through the sense of sight' but 'lean, dwarfish, and hairy – a sluggish, hellish night-abomination midway betwixt beast and man – and usually *touched* before it is *seen*'.[39] In the rubble of the Lovecraft Event we can go further: the adversaries of James's stories are disproportionately and emphatically *Weird*.

- Touch and touchability is central. James's is the horror of the physical universe (a trauma that would trace into the obsessive materiality/-ism of Lovecraft's horror). It is the cloth-ness of the notorious face 'of crumpled linen' in 'Oh Whistle and I'll Come to You My Lad' that makes it so terrible. James even names one of his late stories 'The Malice of Inanimate Objects'. The touchability of his 'ghosts' is not a return to that of their 18th-century cousins: this is a new (Weird) haptos, with little to do with human somaticism, and everything to do with the horror of matter. The most grotesque moment in 'The Ash Tree' is the 'soft plump, like a kitten', with which a just-glimpsed giant spider drops off the bed.

- James's repeated insistence that he is an 'antiquary' is not convincing. He is acutely conscious of capitalist modernity, and a surprising number of his 'ghosts' manifest through it. The demon in 'Casting the Runes' bizarrely announces its intent by means of an advertisement in a railway carriage. The attack which the runes occasion is brought down quite amorally on whoever took them last, according to the depersonalised passings-on of bits of paper. The horror is of the universal equivalent in mass commodification: the runes are Bad Money. Most astonishingly, in 'The Diary of Mr Poynter', what is haunted is not a scrap of fabric nor the materials with which it is made but *the design upon it*: it is the *copied* design, reprinted with explicitly cutting-edge modern techniques, that is the locus for the apparition. This is the work of hauntology in the age of mechanical reproduction.

---

[38] See for example Rosemary Pardoe, 'MR James and the Testament of Solomon' (1999). <http://www.users.globalnet.co.uk/~pardos/ArchiveSolIntro.html>

[39] Lovecraft, *Supernatural Horror*.

- James, like the *haute* Weird, is largely uninterested in plot, subordinating it to his invented strangeness. Unlike Lovecraft, who might simply dispense with it, to present Weirdness in pulp bricolage, 'flashed out', as he puts it, 'from an accidental piecing together of separated things',[40] James goes through the motions of plot; but i) his narrative arcs are utterly predictable, and ii) he knows this, and repeatedly uses formulations like 'I surely do not need to tell you …' or 'It will be redundant to conclude…' or similar. This palpable impatience is underlined by his later increasingly epigrammatic and sparse stories. And like Borges, when he cannot be bothered even with half-hearted narrative, James simply describes his ideas freed of it, as in 'Stories I Have Tried to Write'.

---

[40] Lovecraft, 'The Call of Cthulhu'.

- Most important, of his non-ghost 'ghosts', a disproportionate number have appurtenances of the Weird, and read now as startlingly teratologically ahead of their time. His apparitions are hairy ('The Diary of Mr Poynter', 'Canon Alberic's Scrapbook'), chitinous ('The Ash-Tree'), slimy and/or amphibious ('The Treasure of Abbot Thomas'), totally bizarre ('The Uncommon Prayer-Book'), and more than once, *tentacled* ('The Treasure of Abbot Thomas', 'Count Magnus').

Today's ghost stories are, overwhelmingly, exclusively hauntological, their figures revenant dead in time out of joint.[41] This tradition misremembers itself into existence. Many of its claimed foundation texts can only be so anointed in an act of heroic misrepresentation. Neurotically insistent on his own status as a ghost-story writer James may have been (the titles of his collections reiterate: *Ghost Stories of an Antiquary* (1904), *More Ghost Stories* …, (1911), *A Thin Ghost and Others* (1919), *A Warning to the Curious and Other Ghost Stories* (1925)); however, though he is often considered to have perfected or inaugurated such hauntological work, it is not, for the most interesting part, what defines James's *oeuvre*.

---

[41] Of the sixteen stories in the acclaimed recent collection of 'new ghost stories' *The Dark* (New York: Tor, 2003), various innovations of approach notwithstanding, there is only really one story ('One Thing About the Night', by Terry Dowling) in which the haunt is not a revenant function of the human (and it is not Weird, but the dark of the collection's title). Even more telling is *All Hallows*, the journal of the Ghost Story Society, that contains, according to its own guidelines, work 'in the style of the classic supernatural tale', listing James as its first exemplar. Of the 23 stories in a recent bumper issue (*All Hallows* 43, Summer 2007), one contains a hint of the genuinely Weird ('The Reflection', by S.D. Tullis, haunted both by ghosts and by the 'wrinkled tentacles' (253) which may have trapped them in a mirror). For the others, two time-slips and one imp aside, to be a ghost story is, reasonably enough but *innovatively*, and in contradiction to James, definitionally to be a story of a ghost.

Nor, though, did he write Weird in any straightforward sense. James does not have the visionary abandon of later *haute* Weird. His use of more traditional ghosts and/or occasional folk-ish figures is repeated alongside Weird figures that in shortly forthcoming work would be repudiations of them. James's corpus represents an under-one-roof *co-existence* – that would be all but unsustainable at any but that unique fulcrum moment – of what will later be seen to be hauntology and the Weird, the oppositional dyad.

In this context, the key James story is without question 'Count Magnus'. Here, the 'strange form' from whose hood projects 'the tentacle of a devil-fish' – a Weird, inhuman, Cthulhoid figure who sucks faces from bones – is the *servant* of 'a man in a long black cloak and broad hat', a malevolent human ghost. This is an astounding crossover, its categoric transgression eclipsing any Marvel-DC or Cerebus-meets-Teenage-Mutant-Ninja-Turtle shenanigans. James creates the ultimate tag-team: *Hauntology deploys Weird as its sidekick*.

4. JEAN PAINLEVÉ'S QUANTUM VAMPIRE

There is, in 'Count Magnus', and in James in general, no *aufhebung* of the Weird and hauntological. The two are, I suggest, in non-dialectical opposition, contrary iterations of a single problematic – hence in 'Count Magnus' the peculiarly literal and arithmetic *addition* of Weird to hauntological (with the latter privileged, precisely because James *is*, fundamentally, somewhat ghostlier than he is Weird).

Alongside the fantasist's urge to literalise and concretise problematics, modern – particularly geek – culture is characterised by an accelerating circuit of teratogenesis, new monsters endlessly produced and consumed (exemplified in commodity form by the innumerable RPG and video-game bestiaries; by the coquetry with which films hint at and protect their 'monster shot'; by Pokémon, which deployed the cultural addiction as its slogan: 'Gotta catch 'em all!'). If the contradiction between Weird and hauntological was sublatable, then such drives would surely have led to the monstrous embodiment of any putative 'resolved' third term between Weird and haunt.

Nor is it difficult to imagine what such a synthesis would be. The outstanding synecdochic signifier for a revenant human dead is the skull – mind-seat now empty-eyed, memento mori, grinning, screaming.[42] The nonpareil iteration of the embodied Weird is the tentacle, and by suspiciously perfect chance, the most Weird-ly mutable – *formless* – of all tentacled animals is the octopus, the body of which, a bulbous, generally roundish shape distinguished by two prominent eyes, is vaguely homologous with a human skull.

The shapes are ready, and take little to combine: the Weird-hauntological monster is clearly a tentacled skull (see facing page for my own rendition).

Considering the fecundity and vigour of the teratological drive, the symbolic resonance of its constituents and their apparent topological compatibility for easy crossbreeding, the extreme rarity of the skulltopus in culture is mysterious. There are a very few examples, but the pickings are astoundingly meagre.[43] There is clearly something not right about

---

[42] See for example *The Screaming Skull* directed by Alex Nichol (1958); F. Marion Crawford's 'The Screaming Skull' (in *Uncanny Tales*, London: T. Fisher Unwin, 1911).

[43] There is a five-second animation (http://www.youtube.com/watch?v=ly2jNr1_nro); an illustration (http://tachyonmkg.deviantart.com/art/skulltopus-11383138); a hipster t-shirt (http://www.HowlingGoodTshirts.com/marketplace/87072931/skulltopus_t_shirt); and, most impressively, Becky Cloonan's cover illustration for

it – the two components may imply one another but are *resistant to syncrex*, and the categorical unease this occasions denies the figure proliferation. The Weird and the hauntological generally relate to each other not by sublation, nor, *pace* James, by addition, but by either-one-or-the-otherness, in a manner suggestive of quantum superposition.

The author, with skull and octopus, yesterday.

Bataille's favourite anarcho-visionary marine biologist, Jean Painlevé, understood this. His 1945 'Le Vampire'[44] contains extraordinary footage of an octopus lasciviously crawling over a human skull very similar to it in shape and

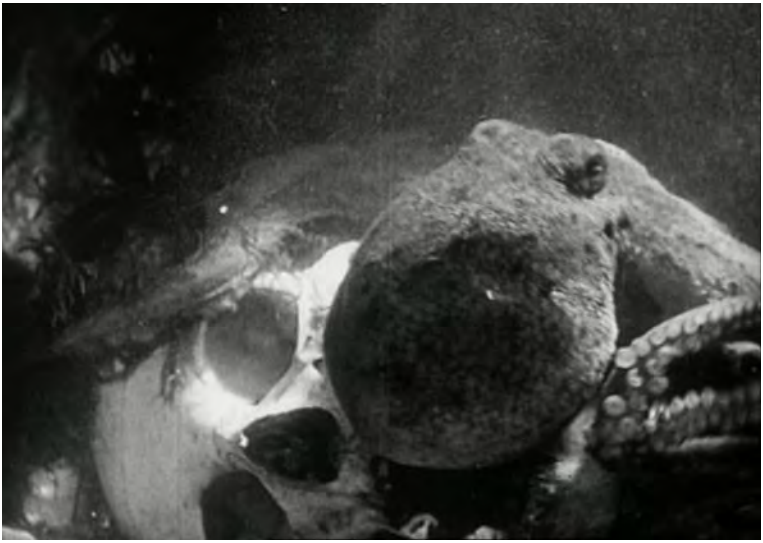
[44] <www.youtube.com/watch?v=wjNh0uZCCLc>

proportion. The octopus should, with that oozability of Weird skin, merge with the skull to become a skulltopus. That event is the asymptote of the interaction we see – but of course it does not happen, because it cannot.



Jean Painlevé, 'Le Vampire' (*Science is Fiction* BFIVD17190)

Instead, Painlevé shows us the unstable haptic flirtation of the two *without merger*. Those seconds are fleeting – the intervening years have distinguished the traditions of skull and octopus, and James's ingenious 'Count Magnus' solution would be hard to pull off now – but are the heart of the film (which otherwise pretends to be about vampire bats and ticks). They are the outstanding cultural example of the superposition of Weird and hauntological. We cannot sustain the skulltopus; as close as we can come is Painlevé's skull-and-octopus-interaction quantum vampire.

5. NEOLIBERALISM, THE SKULL AND THE OCTOPUS

Hauntology and Weird are two iterations of the same problematic – that of crisis-blasted modernity showing its contradictory face, utterly new *and* traced with remnants, chaotic and nihilist *and* stained with human rebukes. We can see these tendencies of the fantastic pulling at each other in the years since James, who inaugurates their contrary twinned birth, in waves of varying speeds depending on the ideological moment. At times one or other iteration might be dominant, but neither can ever efface the other. Opposed but not separable, the traces of the Weird are inevitably sensible in a hauntological work, and vice versa.

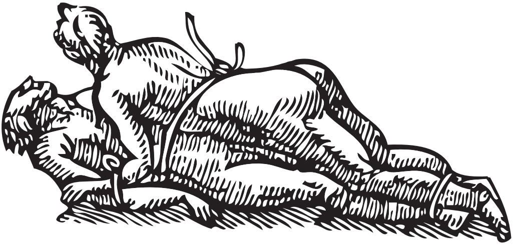
The degree to which one or the other has been stronger has affected the tendency towards their separation as genres of thought and pulp. Since the 1970s their 'separateness' has become dominant, not because there is a 'drive to separate', but as a corollary of the oscillating efficacy of as-simon-pure-as-possible Weird and/or hauntology, for thinking our fraught and oppositional history since the end of Keynesianism, that great Cthulhu-swat and ghostbuster.

In quick and dirty caricature, with the advent of the neoliberal *There Is No Alternative*, the universe was an ineluctable, inhuman, implacable, Weird, place. More recently, however, as Eagleton haunto-illiterately points out, the ghosts have come back, in numbers, with the spectral rebuke that there was an alternative, once, so could be again.

We do not get to choose, however – and why would we want to? If we live in a haunted world – and we do – we live in a Weird one.

The Corpse Bride: Thinking with *Nigredo*

Reza Negarestani



The living and the dead at his command,
Were coupled, face to face, and hand to hand,
Till, chok'd with stench, in loath'd embraces tied,
The ling'ring wretches pin'd away and died.[1]

The punishment imposed by Mezentius on the soldiers of Aneas should be inflicted, by coupling him to one of his own corpses and parading him through the streets until his carcass and its companion were amalgamated by putrefaction.[2]

---

[1] Virgil, *The Aeneid*, VIII 483-88.

[2] Erinensis, 'On the Exploitation of Dead Bodies', *The Lancet*, 1828-9: 777.

A Prelude to Putrefaction

In the eighth book of Aeneid (483-88), Evander attributes an outlandishly atrocious form of punishment to Mezentius, the Etruscan King. However, it is not Virgil who first speaks of this punishment, for before Virgil, Cicero cites from Aristotle an analogy which compares the twofold composite of the body and soul with the torture inflicted by the Etruscan pirates. Revived during the reign of the Roman Emperor Marcus Macrinus, the notoriety of this atrocity survives antiquity and the Middle Ages. In the sixteenth century, the horror of this torture is expressed, once again, by a popular emblem called *Nupta Contagioso* showing a woman being tied to a man plagued by syphilis, at the King's order. Widely distributed throughout Europe, the emblem continues to reappear in different contexts during the Renaissance and even toward the nineteenth century. *Nupta Contagioso* or *Nupta Cadavera* literally suggests a marriage with the diseased or the dead: a forcible conjugation with a corpse, and a consummation of marriage with the dead as a bride.

Haunted by the unusually philosophical insinuations of this punishment as well as its subtle imagery, to which human imagination cannot help contributing, Iamblichus and Augustine – like Aristotle – ruminate on the Etruscan torture. They both adopt it as something more than a fundamental allegory in their philosophies: they see in it a metaphysical model that exposes and explains the condition(s) of being alive in regard to body, soul and intellect.[3] Jacques Brunschwig, in his 1963 essay *Aristote*

---

[3] For more details on Aristotle and the fragment on the psyche see A.P. Bos, *The Soul and its Instrumental Body: A Reinterpretation of Aristotle's Philosophy of Living Nature*, (Leiden: Brill, 2003).

et les pirates tyrrhéniens, describes the baroque details of the Etruscans' punishment. A living man or woman was tied to a rotting corpse, face to face, mouth to mouth, limb to limb, with an obsessive exactitude in which each part of the body corresponded with its matching putrefying counterpart. Shackled to their rotting double, the man or woman was left to decay. To avoid the starvation of the victim and to ensure the rotting bonds between the living and the dead were fully established, the Etruscan robbers continued to feed the victim appropriately. Only once the superficial difference between the corpse and the living body started to rot away through the agency of worms, which bridged the two bodies, establishing a differential continuity between them, did the Etruscans stop feeding the living. Once both the living and the dead had turned black through putrefaction, the Etruscans deemed it appropriate to unshackle the bodies, by now combined together, albeit on an infinitesimal, vermicular level. Although the blackening of the skin indicated the superficial indifferentiation of decay (the merging of bodies into a black slime), for the Etruscans – executioners gifted with metaphysical literacy and alchemical ingenuity – it signalled an ontological exposition of the decaying process which had already started from within. Also known as the blackening of decay or chemical necrosis, *nigredo* is an internal but outward process in which the vermicular differentiation of worms and other corpuscles makes itself known in the superficial register of decay as that which undifferentiates. For the Etruscan pirates, chemistry started from within but its existence was registered on the surface, so to speak; explicit or ontologically registered decay was merely a superficial symptom of an already founded decay, decay as a pre-established universal chemistry. The victim could only be unshackled from the corpse and released when decay finished its ascension from within to the surface. Therefore the so-called climax of the punishment – the blackening of the body – coincides with the superficial conclusion of decay, the exposition of decay on an ontological level.

In a now lost piece, the young Aristotle makes a reference to the torture practiced by the Etruscan pirates.[4] In that text, Aristotle draws a comparison between the soul tethered to the body and the living chained to a dead corpse (*nekrous*):

> Aristotle says, that we are punished much as those were who once upon a time, when they had fallen into the hands of Etruscan robbers, were slain with elaborate cruelty; their bodies, the living [*corpora viva*] with the dead, were bound so exactly as possible one against another: so our souls, tied together with our bodies as the living fixed upon the dead.[5]

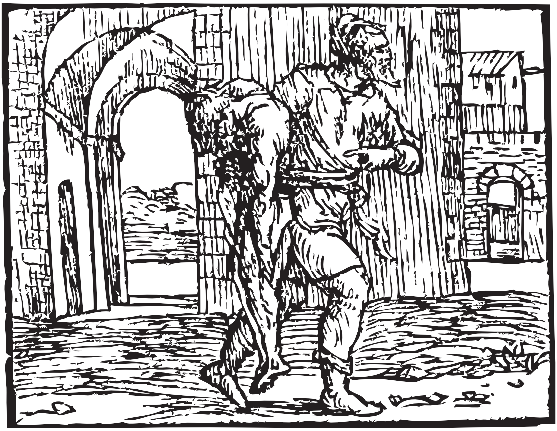
Whether this fragment points to a Platonic phase in the philosophical life of Aristotle or not, it provides us with a unique resource for discovering the less explicit ties between his *Metaphysics* and *De Anima*. Accordingly, it also holds a key for understanding the severed ties between Aristotle's philosophy and that of Plato on the one hand and the enduring bonds between Aristotle and Scholasticism on the other. Yet more ambitiously, this fragment subtly points to a moment in philosophy when both the philosophy of Ideas and the science of being qua being are fundamentally built upon putrefaction and act in accordance with the chemistry of decay. It is the moment when beings must undergo necrosis and decay in order to remain in being and the Ideas must be founded on an intensive necrosis and an extensive decay in order to remain in their essence and to synthesize with other Ideas. In other words, this moment marks a necessity for Ideas – even the Idea of ontology itself: in order to be active intensively and extensively, inwardly and outwardly, the Idea must first be fully necrotized and blackened on all levels, intensively and extensively.

---

[4] Aristotle's fragment regarding the body-soul composite and the Etruscan torture is believed to be a part of *Eudemus* or *Protrepticus*.

[5] Quoted by Cicero from Aristotle in *Hortensius*. Also see *Saint Augustine Against Julian (Writings of Saint Augustine, V. 16)*, (Washington, DC: The Catholic University of America, 1957). Augustine uses the same quote from Cicero.

The following is a disorganized venture – more in line with grave robbers and necrophiles than with archaeologists and scholars of history – to disinter the twist inherent to the fragment associated with Aristotle and to delve into the moment when, prior to all arrangements and establishments, a pact with putrefaction must be made; the moment of *nucleation with nigredo*, as we must call it.



NECROPHILIC REASON

Aristotle's fragment regarding the Etruscan torture bears a deeply pessimistic irony; it is not the supposedly living body which is tethered to a corpse to rot, because it is exactly the soul qua living which is bound to a corpse – namely, the body. For Aristotle, the soul, as the essence of a being, needs a body to perform its special activities, and it is the responsibility of the soul to be the act of the intellect upon the body. Therefore this necrocratic confinement is both the price and a means of having a body as instrument, and then using this instrument to govern and eventually unite beings. The soul, in this sense, has two activities, inward and outward. The outward activity of the soul is the actualization of the body according to the active intellect (*nous*) which is immortal; in other words the extensive activity of the soul is the animation of the body according to the *ratio* (reason) derived from the *nous*, the intensive and inward activity of the soul. The inward activity of the soul is its unitive activity according to the intellect as the higher genus of being qua being. The intensive activity of the soul is the act of bringing the universe into unison with the intellect according to *ratio*; for this reason, the intensive activity of the soul coincides with the enduring of the soul in its relation to the intellect, which itself is internal to the soul. Here, the intensive and extensive, inward and outward activities of the soul must be in accordance with one another in order for the world to be intelligible and, in its intelligibility, to move toward intellect in proportion to reason.

If the intelligibility of the world must thus imply a 'face to face' coupling of the soul with the body qua dead, then intelligibility is the epiphenomenon of a necrophilic intimacy, a problematic collusion with the rotting double which brings about the possibility of intelligibility within an inert cosmos. The intelligibility allotted to the body as *corpora cadavera* by ratios of the intellect (or reasons) – each inherent to a different type or gradation of the soul – animates the world according to the intellect. Yet in doing so, reason reanimates the dead rather than bestowing life upon it; for in terms of the Aristotelian body qua cadaver, intelligibility is the reanimation of the dead according to an external agency. Reason grounds the universe not only on a necrophilic intimacy but also in conformity with an undead machine imbued with the chemistry of putrefaction and *nigredo*.

Both in Etruscan torture and in Aristotle's fragment, the living or the soul is tied to the dead or the body *face to face*. The Greco-Roman motif of the mirror is obviously at play here; one sees itself as the other, the perfect matching double. However, the great chain of philosophers from Aristotle to Augustine and beyond only tell us about one side of the mirror, shamelessly underestimating the understanding of both the living and the dead. They tell us that the soul sees itself as the dead party whilst chained to the body. But this is surely a ridiculous attempt to unilateralise the mirror motif, for not only does the living see itself as dead, but the dead also looks into the eyes of the living, and its entire body shivers with worms and dread. It is indeed ghastly for the living to see itself as dead; but it is true horror for the dead to be forced to look at the supposedly living, and to see itself as the living dead, the dead animated by the spurious living. Neither Aristotle nor Augustine tell us about this infliction upon the dead of the burden of the living, this molesting of the dead with the animism of the living. It is the Barbarians who formulated and exposed the ulterior cruelty of the Etruscan torture in retaliation for the Romans' atrocities: they slaughtered their own cattle, disembowelled them and then forced the Romans inside the carcasses in such a way that only the talking heads of the soldiers protruded. In doing so, they exhibited the farce of vitalism by ventriloquising the dead with the living.

The binding of the soul to the body as a tying of the living to the dead is later arithmetically captured by Aristotle in the formulation of a metaphysical model which is best understood arithmetically, or at least geometrically, as scholastic philosophers preferred. In vitalizing matter and actualizing it, the soul needs a body as an apparatus by which the universe of beings can be led toward the intellect which causes the noumenal universe to exist. In order both to use and to be used by the body under the direction of the intellect, the soul must first remain in itself. And conversely, in remaining in itself, the soul must animate the body and bring about the synthesis and unification of bodies. In other words, in simultaneously governing beings and conducting them toward being qua being (higher genera of being), the soul must first remain in itself and extend beyond itself. For Aristotle, this metaphysical model, the model of intelligible ontology, is arithmetically distilled as *aphairesis* (*apo*+*airein*, abstraction), a taking away or subtraction. As an Aristotelian mathematical procedure, *aphairesis* consists in two vectors of operation, of negative and positive directions in regard to each other, in diametric opposition but synergistically continuous and reinforcing. For *aphairesis*, as taking away or subtraction, emphasises simultaneously removal (that which is taken away) and conservation (that which is left behind by removal) – the removed and the remainder. A soul coupled with the body mixes with the impure –

since the body debases its essence – and at the same time approaches being qua being by remaining in itself (i.e. by ascending in its purity). For Aristotle, only subtraction can make such double-headed and simultaneous mobilization possible. *Aphairesis* or subtraction, accordingly, maps the vectors of the *mobilization* and *effectuation* of reason. *Aphairesis* is thus a procedure whereby the soul can be captured simultaneously in the sense of its belongings (or bodies) and in its movement toward *nous* which sheds those belongings as it approaches the intellect – an arithmetic formulation of the Etruscan metaphysical cruelty.[6]

The Aristotelian procedure of *aphairesis*, or subtraction, as a formulation for the metaphysical model of intelligible ontology, resurfaces explicitly during the Middle Ages – especially during the period known as High Scholasticism (1250–1350) – creeping beneath metaphysical systems, alchemical models and theological creeds. However, before affecting scholasticism, Aristotle's model implicitly exerts its forbidden influence on Neo-Platonism, especially through apophatic or negative theologians for whom the ineffability of God must be exposed by *aphairesis* or abstraction. Plotinus states that the reality of the One (*hen*) cannot be explained through the epistemological registers or attributes (belongings) which it shares with humans. Therefore, the Divine must be stripped of all its belongings by *aphairesis*, a procedure which takes away all that exists extraneously and negatively contributes to all that remains and itself progressively diminishes (becoming sublime). Here, the conceptual abstraction of *aphairesis* returns to Aristotle's subtractive model, seeded within his fragment on the Etruscan torture: the coupling of the soul with the body qua belonging is necessary in order to shed belonging and lead toward being qua being. This is so given that being qua being is a genus of being which persists and remains under any condition or environment synthesized by other beings whatsoever. In other words, being qua being is that which continues to remain after all belongings are shed, removed and taken away. This is what makes *aphairesis* the fundamental procedure in revealing or exposing the One, as employed for the most part by neo-Platonists such as Plotinus and Proclus.

---

[6] *Aphairesis*, as a subtractive correlation between the soul and the body, simultaneously offers the soul the capacity of having a body as an instrument or belonging, and the opportunity of preserving its ultimate correlation with intellect. Arithmetically, in *aphairesis* or subtraction, the amount that is negated or taken away marks the dying correlation of a magnitude with its belongings (as the correlation of the soul with the mortal body). The amount that remains after subtraction, however, represents the correlation between the remainder and that which continues to remain regardless of the magnitude of subtraction. This can be expressed as the undying correlation between the soul and the intellect.

Both Aristotle's and Plotinus' formulations of *aphairesis* are grounded on one precondition, which can be summarized in terms of *conservation after subtraction*: despite being chained to the festering corpse or being subtracted, the soul is able to conserve some of itself and render the body intelligible. In the same vein, no matter what is taken away from the Divine, it will continue to remain as the One already there. Correspondingly, if magnitude Y is subtracted from magnitude X the result can be either zero, or *x* (where *x* is a remainder from X). Both Aristotle, in regard to the soul vis-à-vis the intellect (as part of the soul which remains under any condition), and Plotinus, in regard to the One, take conservation of a remainder for granted. The world cannot be intelligible and move toward intellect without the assumption that the subtraction or mortification of the soul by the body does not lead to the total erasure of the soul in the first place. Aristotle's system of metaphysics is thus built upon an assumption which has been taken for granted: that for every subtraction, there is a possibility of conservation in the form of a remainder, and for every remainder, the possibility of persistence in remaining, i.e. a resistance toward further subtraction through remaining in itself.

The coupling of the soul with the body could indeed lead to the instant mortification of the soul, thus eliminating the possibility of the soul's conferring intelligibility on the universe. But this is not the case, for the soul remains in itself and brings about the possibility of intelligibility. For this reason, the possibility of intelligibility is based on the possibility having a conserved part or remainder after subtraction – that is, the continued possibility of the soul after coupling with the dead and being putrefied by its rotting double. Only when this possibility is taken as a determinable and certain possibility can reason be associated with the intelligibility that issues forth from *nous*. The persistence of the soul in conserving its essence, or the determination of the One in remaining, certainly wards off the threat of becoming the dead qua the body or belonging; but only at the cost of becoming intimate or problematically hooked up with the dead. We shall now see how the insistence in *remaining so* or *conservation* in regard to subtraction pushes the soul to a more rotten depth of *nigredo*, and how reason exhumes a more problematic intimacy with the *nekrous*.

HORROR IN THE NEGATIVE

Subtraction is an economical mobilization of non-belonging in two directions: (1) the shedding of belongings or extension by means of *expendable* belongings; (2) remaining or intensive resistance against the expendability of belongings. The subtractive procedure of *aphairesis* bifurcates into two directionally opposite but synergistic vectors – the extensive and intensive vectors of subtraction. The outward and extensive vector of subtraction is the one by which belongings are taken away or by which the soul can extend beyond itself via a body. The latter, however, is the vector of remaining so and as such. As the inward vector of subtraction, remaining – or, more accurately, the persistence of the remainder – characterizes an intensive vector of subtraction whereby that which continues to remain brings about the possibility of being qua being or the Ideal. It is the persistence of the soul in remaining after its katabatic contact with the body that opens up the opportunity of its coming into unison with the intellect. Similarly, only that which continues to remain despite being stripped of its belongings or attributes can eventuate the One (*hen*) and the Idea of being qua being; for once again, being qua being is 'being in *remaining* so and as such'. To this extent, not only must the soul remain after its necromantic contact with the body, but also at least a part of it must continue to remain. In other words, Aristotle's model of conservation (*viz.*, having a conserved part after subtraction) might be based on the determinability of having a remainder in the first place, but it mainly concerns the continuation of the remainder.

Having a remainder after subtraction is not sufficient for the march toward the intellect, or for the exposition (explanation) of the Idea of being qua being. The remainder must *continue* to remain – this is the insinuation of the metaphysical model of conservation. The possibility of the remainder is necessary but not sufficient, for its sufficiency lies in the possibility of the remainder in remaining.

The remainder as an exposed and determinable quantity must be hosted by the indeterminable vector continued remaining, namely, *to remain*. The remainder alone as a determinable quantity is exposed by what is subtracted, but *to remain*, or in other words, to persist in remaining, coincides with the continuation of subtraction – a greater and greater subtraction. In short, the more the remaining persists, the more it is subtracted, the less the remainder gets. Persistence in remaining means to shrink more, because the act of remaining coexists with the progression of subtraction. To remain is at the same time a persistence in subtraction (hence mobilization of the vector that takes away belongings) and the continuation of the remainder in remaining less. R as the remainder reveals something *already there*, but persistence or continuation in remaining suggests insistence on what is *always* already there and can only be perpetuated through rs smaller than R. A system of cosmogenesis whose Ideals and infinities have been established prior to its building processes – as *the ones already there* – has a certain destiny with regard to the horror genre: Its horror stories are inherently concerned with decay even if they deal with other themes and dabble in other affairs.

To provide further clarification as to how the continuation of the remaining or remaining in itself is only possible in remaining less – subtractive extension and diminutive intention – the procedure of *aphairesis* can be mathematically (albeit schematically) demonstrated. Take two geometrical magnitudes A and B, where $A > B$ as the Ideal ground of the procedure and a guarantee for its continuation (iterative subtraction). The procedure starts by subtracting the greatest multiple of the smaller magnitude B (henceforth mB) from the greater multiples of the greater magnitude A: $A - mB = R$. The result of the subtraction as hitherto a conserved part is the remainder R which is less than the smaller magnitude B ($R < B$). Since the remainder R is less than the smaller magnitude B, the procedure is continued by subtracting the greatest multiple of the remainder R (henceforth nR) from the smaller magnitude B: $B - nR = r'$. The result of the subtraction is again a remainder but it is less than the previous remainder ($r' < R$). The procedure of subtraction (*aphairesis*) will continue in this way to reveal that which remains as the one already there. For this reason, the persistence in remaining or the act of remaining (to remain) – as the continual result of the subtractive operation – can only invest itself in *remaining less* and as ontological decay. The continuity of remaining and thus the revelation of the One (already there) and being qua being (being in remaining so and as such) is only attainable, and must be conducted, through diminution and decay: $R > r' > r'' > \ldots$

Fig. 1. Extensive and intensive vectors of subtraction

The tenacity of the soul – as an act of the intellect upon the body – in conserving its inner parts brings life to the universe as an intelligible principle. Yet this insistence on survival or remaining introduces decay and *nigredo* into both intelligibility and vitality. The persistence of the remainder in remaining (*viz.*, to remain) is submission to the *de facto* reign of putrefaction, the universal of intelligibility and the particular of a problematical openness to the dead. For the body which is nourished by the soul, the mandatory submission of the soul to decay (*diminutio* or lessening) is in fact the mimesis of the dead by the soul. By mimicking the dead, the soul can repose intimately with the dead until it is reclaimed through reason by the intellect. But the exposition of the intellect is too contingent upon its correlation with the soul through reason which is itself aligned with decay or the intensive diminution undertaken by the soul. Accordingly, *to remain* as such is equal to intensive diminution coupled and differentially connected to extensive decay[7] – the shriveling soul whose continuity extends to the necrotized body through the worms which twist in and out of it:

> For as the Etruscans are said often to torture captives by chaining dead bodies [*nekrous*] face to face with the living, fitting part to part, so the soul seems to be *extended throughout and affixed* to all the sensitive members of the body.[8]

Mapping the vector of intensive decay or diminution, the act of remaining bridges the gap between the subtractive extension and the interiorization of no-thing or no remainder. If the soul must conserve the inner parts of itself (corresponding to the higher genera of being qua being) after coupling with the body, then it must remain itself at the same time as extending beyond itself. However, as argued above, remaining (as of the soul) is not possible except through remaining less, that is to say as intensive diminution of the remaining. Yet what is the guarantor of remaining *per se*, or to be exact, what guarantees that the remaining shrinks and becomes less? Keeping in mind that remaining in itself is *remaining less*, intensive diminution is reinforced by extensive subtraction. The answer is that only through the interiorization of nothing qua non-belonging, can remaining continue to remain, or to be precise, continue to *remain less*. Without *nothing* being interiorized diachronically within the remaining, the remaining cannot continue to become less and thus persist. This nothing qua non-belonging cannot be simply equal to the exhaustion of the remaining; nor can it be equated with the Idea of being qua being (*viz.*, the One) which sheds belongings. In other words, *nothing* as the guarantee of 'continuation in remaining' is neither the content of the exhaustion, nor can it be taken as correlated with the remaining. Interestingly, the reasons for this resistance toward correlation with what remains and what is removed lies in the premises of the act of remaining – persistence in remaining assumes two basic Ideas: diminution or shrinkage, and continuity in diminution. Not only must that which remains/survives become less, it must also maintain continuity in lessening. For this reason, the guarantor of remaining must simultaneously be the impetus of the intensive diminution and induce a continuity in remaining (in remaining less) from outside. The guarantor must be autonomous and separate from that which remains, because if correlated with that which remains, it will be indexed by exhaustion. Yet the guarantor cannot be the subject of exhaustion for if it were then it could not maintain and guarantee the lessening of the remaining, that is to say, the continuity of remaining. What is itself consumed cannot sufficiently guarantee the exhaustion of that which correlatively succeeds it.

---

[7] In medieval literature and painting, the intensive and extensive vectors of decay are imagined as a shriveling body from which a cosmic range of other beings emerge. While the shriveling body which folds back upon itself visually narrates the intensive aspect of decay; worms, corpuscles and other nameless beings which come forth from the contracting body stand for the extensive vector of decay. As the inheritor of the alchemical tradition, Giordano Bruno sees the intensive decay of the shriveling body in the *caput mortuum* (death's head) or the residuum of a substance after its attributes have been extracted by distillation; while the extensive vector of decay is seen by Leibniz as worms which contain smaller worms, *ad infinitum*.

[8] Iamblichus, *Protrepticus* 8, (Leipzig, 1893), 47. 21-48.

In short, if the guarantor of remaining is correlated with the act of remaining, it will be indexed by exhaustion and thus cease to influence. Any disruption in the influence of this guarantor induces a discontinuity in the persistence in diminution, which in fact is the continuation of remaining. Moreover, the guarantor of remaining should not be sought in the extensive vector of subtraction by which belongings are taken away, because the subtracted magnitude cannot influence the fate of remaining magnitude. Therefore, not only must this guarantor evade correlation with that which remains (something), but it must also inspire the act of remaining, or in intensive terms, remaining less or diminution. Exterior to the Idea of ontology (namely remaining), the guarantor of remaining as such is *nothing* – the impossibility of being correlated either with what is removed or with what remains. To this extent, this impossibility of correlation and belongings entails both diachronicity and exteriority. The guarantor of remaining – no-thing – must be diachronic and external to the remaining, otherwise the remaining cannot maintain its continuity, whose ontological constitution is anchored by remaining less. By approximating no-thing as radical exteriority, the remaining can continue to remain and shed its belongings, that is to say, it can remain less or remain in itself. Remaining in itself is the medium of being qua being and hence the medium by which union with the intellect and the exposition (revelation) of the One is possible. But this medium only takes on its structure in so far as the remaining approximates or limitropically approaches no-thing or the impossibility of belonging in order to maintain an intensive diminution necessary for remaining less or remaining in itself. Intensive diminution is in itself synchronous only by virtue of its disjunction with a diachronic exteriority which ontologically underpins the continuity of the remaining in remaining less.

In order to remain in any instance, first of all nothing, as impossibility of belonging, must be prioritized and postulated in its exteriority. The reason for this prioritization of nothing as a non-correlatable exteriority is to satisfy the prerequisite ontological status required for effectuation of the remainder in any instance. This prerequisite status is the intensive diminution or remaining less, for the diminution of the remaining is nothing but remaining as such. In subtraction, diminution or intensive decay is at the same time a solution to the problem of remaining and the very ontological constitution of the remaining *per se*. However, this solution simply cannot work, or in other words, is not able to be correlated with its problem, unless *nothing* as radical exteriority is taken as a necessity. In order to shed belongings and remain less, the uncorrelatable primacy of non-belonging must be affirmed. In other words, *nothing* must be prioritized prior to all arrangements and establishments of the remainder.

Accordingly, something that remains, or *something* in general – as that which remains – always testifies to the binding or interiorization of nothing as priority and primacy. In the persistence of its remaining, the remainder must shed its belongings (or remain less) by affirming the primacy of nothing, for only nothing, as the impossibility of belonging, can guarantee the continuing shedding of belongings. This relation between solution and problem, secured by means of the prioritization of nothing, can be explained in Aristotelian terms as well: Chained to the body, the soul cannot bring the universe into unison with the intellect or bring about the possibility of progression toward *nous* (the problem) unless it continues to *remain* according to an inner part of itself, conserving the innermost depths of its essence (the solution). Here the solution, which pertains to remaining, cannot be correlated with the problem without submitting to the priority of nothing or – in terms of the soul – the void. The soul must submit to the priority and primacy of nothing or the void in order to solve its problem in regard to the intellect.

In short, intensive diminution or remaining less is the solution to the problem of remaining, but this solution itself must bind the priority and primacy of nothing to the fullest extent. In this sense, nothing as exteriority is interiorized to provide that which remains with the ontological constitution requisite in remaining as such – but only as a problematic bond with nothing, which, as the impossibility of belonging, cannot be relieved through being captured by correlation. If nothing qua non-belonging is uncorrelatable, then it is the embracing of *nothing* by the soul or the living that becomes the manifest problematic. In order to survive or enlighten with life, the soul must either sleep with the dead, or accede to the priority and primacy of the void as its internal guide. What could be worse for vitalism than at once being animated through a necrophilic alliance, and simultaneously, protected under the aegis of the void? It is decay that provides the bridge between the latter (the problematic embracing of nothing) and the former (the subtractive bond with the body or belonging). That which arises from death can only peacefully repose among the dead, as living.

The interiorization of nothing through which the remainder continues to remain and is subjected to ontological shrinkage by remaining in itself, deploys a subtractive vector which is implicit in remaining. This internalized or implicit subtractive vector corresponds with the persistence of the remainder, or more precisely, it coincides with the survival of the remainder in its resistance to the explicit subtractive vector through which belongings are exteriorized. The medium of survival and its constitution are thus, problematically, the implicit apparatus of death. It is in this sense that the persistence of that which remains – the innermost depth of the soul, the intellect or the One – is ultimately indeterminable; for it is not only determined by the exteriorization of belongings but also by that *nothing* to which it must implicitly submit in order to remain (less). Once the intellect, as the highest genus of being qua being, is deprived of its determinability, reason, in its mission to redeem the world on behalf of the intellect, reclaims the world for a problematic death qua life instead.

As for Plotinus' metaphysics, the horror of abstraction (*aphairesis*) is akin to the horror implicit in the Idea of ontology or remaining as such: the apogee of the One is undermined by another culmination which emphatically precedes it, yet cannot be chronically culminated. The search for the Ideal turns out to be a *sub rosa* search for the problematic on behalf of nothing, conducted all along through the bottom-up chemistry and differential dynamics of decay and putrefaction. As we shall see, the guarantor of any Idea of persistence, regardless of its Ideal or telos, is *nothing*. Remaining might be a solution in regard to finding a medium through which the Ideal can be explained, but such a solution brings with it the problems inherent to the clandestine alliance with nothing. Persistence under any subtractive condition is definitely a fitting solution for the revelation of the One and the effectuation of being qua being, but this solution was already infested with problems which do not belong here. Our survival or continuation in remaining is indeed a vitalistic solution, but it is not an authentic or genuine one, for it inherently transmits an entirely alien set of problems to which it can neither correlate nor belong. Survival, in this sense, is the remobilization of problems whose nature is radically detrimental to our solutions.

In contrast to the exteriorization of belongings, the exteriority of nothing in its primacy is internalized in order that the remainder might remain and survive. Remaining is a trajectory whose *continuity* is described by the removal of its attributes and belongings, but whose *continuation* is guaranteed only by its diminution and decay. To stave off the realism of the dead which follows from its coupling with the body, the soul disguises its putrefaction as survival; that is to say, reformulates the problem of decay according to new correlations with its own Ideals and reasons. However, in distracting the dead, the soul is exposed to problems whose concerns belong neither to the living nor to the dead. *Katabasis,*[9] or the descent of the soul, is not radical enough, for it conveys the profit-seeking openness of the soul to the body as an instrument, an *economical* openness based on mutual affordability. Yet it is exactly this conservationist affordance of the soul-body composite that causes the soul to be cracked open by nothing from within. The first descent of the soul is only a twist that opens the soul on to an ultimate *katabasis* where the soul is directly – albeit problematically – fettered to nothing, kept alive to rot away in and for itself. It is here that Aristotle's analogy of the relation between body and the soul with the tribulation imposed by the Etruscan pirates proves to be, if not wrong, then problematic; for it sincerely suggests the necrotization of the soul by the body only to divert attention from a second necrosis, blacker than the first.

---

[9] In Greco-Roman ritualistic tradition, *katabasis* refers to a journey which is characterized by descent (usually to the underworld). *Katabasis* is a depthwise and pro-ground (*profundus*) movement; for that reason, in scholastic alchemy, it is often associated with *nigredo* or depthwise and intensive decay.

The soul is necrotized in its mission to govern the universe and vitalize matter according to the intellect. In full conformity with its vitalistic intention, the soul assumes an intimacy with nothing: it is invaded by *nothing* from behind (*a tergo*). The second necrosis of the soul – shrouded in the explicit cruelty of the first – is its unbreakable and wilful bond contracted with nothing in order to remain, a tie fully based on reason. It is only in the second necrosis that the climax of the Etruscan torture finds its proper narrative. The fastening of the living to the dead is a culmination from the perspective of a collective gathering, but surely of minor interest when we know that the living, the soul, is itself rotting. The real climax of the Etruscan torture, for this reason, is the *feeding* of the living while strapped to the dead. It is only this second necrosis that fully suggests the culmination of the Etruscan torture: while tethered to nothing, the soul qua remainder continues to live, as its continuation in remaining (less) is guaranteed by the primacy and priority of nothing. Bound to nothing, the remainder effectuates the act of remaining in the form of diminution and decay whilst fastened to nothing as a constitutional primacy. The two necroses of the soul, to this extent, can be categorized, as regards of their extensive and intensive development (*-plication*) in metaphysical cruelty and nigrescent *katabasis*, as *explicit* and *implicit* necroses of the soul. The former – the explicit necrosis of the soul – is the coupling with the body qua *cadavera* in order for the soul to extend beyond itself by means of subtracted or necrotized belonging (the body). The latter – the implicit necrosis of the soul – is entailed by the internalization of nothing in its primacy in order to shed belongings and remain in itself. The two necroses of the soul upon which the universe and intellect are fixed bring about the possibility of ontology as a great chain of corpses whose arrangement is determined by their explicit and implicit indulgence in necrophilia. Aristotle fully exposes the first necrosis only to exploit its explicit drama to conceal the second.

THE IDEA AND THE WORMS

The subtractive correlation between vitalism and matter, we argued, is accomplished by means of explicit necrosis, or the soul-body composite according to Aristotle's system. Yet the explicit necrosis is linked to an implicit necrosis whose necessity is fully supported and affirmed by reason. For the sake of clarity, we shall delineate the nature of the second necrosis before moving forward: The subtractive correlation between matter and vitalism is intensively conducted through a medium which constitutes the very Idea of ontology – that is, of remaining so and as such. Yet remaining as remaining less – diminution or intensive decay – requires a guarantee whereby it can be perpetuated or at least made possible in both its lessening and its continuity.

While this guarantor cannot be included by the extensive and intensive vectors of subtraction, it can be problematically posited in such a way that the remaining can maintain its diminution and continuity by approaching it as a limit process. This guarantor is the impossibility of belonging or the disjunctive nothing which, once presupposed by the remainder, can impose the continuous shedding of belongings. Recall that the shedding of belongings is registered extensively as the subtractive extension or exteriorization of belongings, and intensively as remaining, or more accurately, remaining less. In a similar vein, Plotinus' procedure of *aphairesis* or abstraction exposes the One through remaining as an ontological medium, but in doing so it exerts the imposition of nothing or no-one. It is in this sense that for both Aristotle and Plotinus, the medium of revelation for the Ideal (that which continues to remain under any subtractive magnitude) is diminution and intensive decay. Yet this is not the only twist inherent to the problem of exposing or explaining the Ideal. The second – implicit – necrosis brings a far more convoluted twist to the assumed correlations between the Ideal, the problem and the solution.

We argued that both the intellect and the One as the Ideal posit problems in regard to their ontological status (being qua being) as related to the universe or beings. Speaking somewhat reductively, part of the problem posited by the intellect regards channelling the progression of the universe into unison according to reason. Likewise, the problem posed by the One is the exposition of the One as the Ideal of being qua being – that is to say, the exposition of the One as that which is indifferent to, or even resists, the subtractive mobilization of belongings. The solution lies in the establishment of an ontological medium which not only reinforces subtraction but also remains in itself and according to the Ideal. In other words, to settle the problem of exposing Ideals, the solution must abide by the ontological status of 'the Ideal as that which withstands any subtractive magnitude'. For this reason, the solution must be correlated both to subtraction and to the ontological medium of the Ideal. Although correlated to subtraction from one side, the ontological intension of the solution must only correspond to that of the Ideal. Otherwise it undoes the problem by dispossessing it of its assumed ground.

Now, if the ontological intention of the Ideal is indifferent to subtraction, then in order to explain the Ideal, the solution must expose the continuity of the Ideal in remaining, or more accurately, the intractability of the Ideal in regard to subtraction. Accordingly, then, remaining in itself – or in other words, *remaining as such* – constitutes the solution. However, as argued, in order to expose the Ideal, *remaining as such* must correspond to the act of remaining less, which is impossible without the intervention of nothing. Therefore, the solution (*viz.*, remaining as an ontological medium) radically betrays the Ideal because, firstly, it submits to the priority and the primacy of nothing; and secondly, it internalizes the disjunctive exteriority of nothing in order to realize and authenticate itself. To this extent, if the Ideal is to be explained (the problem), the solution must essentially be posed on behalf of *nothing* because only through remaining less, or more exactly, decay (the solution), can the Ideal, the problem and the solution encompass each other as Idea. As the medium cementing the Idea in its most concrete – albeit volatile – form, decay or remaining (less) entails *nothing* on both planes of exteriority and interiority because through the intervention of nothing, the true Idea of remaining can be underpinned in its continuity, diminution and being. The Idea of something as that which remains or survives subtraction even transiently points to the essentially duplicitous nature of this intervention. The intervention or imposition of nothing in its priority and primacy ensures the act of remaining and persistence of something, but at the same time this vitalistic triumph takes place by remaining less or approximating nothing. To put it differently, the imposition of nothing imparts an inherently duplicitous nature to the Idea of ontology: remaining is at the same time a vitalistic persistence and an intensive decay on the part of a problematic intimacy with nothing. Decay conveys this duplicity in the most subtle manner where the Idea of *remaining per se* becomes that of *remaining less* and the Idea of ontology as such coincides with the second necrosis.

Correlated to this double-dealing solution, not only is the problem betrayed, but also the Ideal is undermined by virtue of its correlation with the problem. Rather than securing the Ideal as ground, the correlation between the solution (i.e. remaining) and the problem (i.e. explaining the Ideal) perforates and ungrounds the Ideal with nothing. If the correlation between solution and problem is built upon a double-betrayal and the duplicity of solution, then such correlation twists itself out of its assumed intension rather than terminating it – That is, given that this assumed intention is either that of exposing the Ideal or that of effectuating the Idea of *something* (anything) through remaining. The Idea of correlation – that is, the correlation between solution and problem – does not need to be terminated so that *nothing* can be imposed. On the contrary, the correlation *per se* is what is fundamentally needed to bring about the imposition of nothing as the exposition of the problematic. By problematic we mean the submission to the priority of nothing in order to effectuate the Idea of something or the short-circuiting of ontological intention with the intervention of nothing in order to bring about the possibility of ontology. In pursuing the ontological intension of the Ideal, the correlation between the solution and the problem traffics and imposes the intention of nothing as the implicit constitutional necessity and the radical exterior of the Ideal and its intention. Correlation, in this sense, is equal to the very Idea of twist (*flectere*), for which inflection (pursuing the intension of correlativity) is already a deflection (inviting that which is radically exterior to that intention). In twisting into something, the correlation between solution and problem, twists into nothing; and in twisting into nothing such correlation twists back into something. Only through these twists in and out can the Idea of something be resonant. The correlation between solution and problem is effectuated as intensive decay or depthwise putrefaction (*nigredo*), but it is the twist of correlation that makes for the peculiarly vermicular sinuosity of implicit putrefaction, the second necrosis. If the explicit necrosis, the coupling of the soul with the body is differentially consummated by worms' bridging of the dead and the supposedly living, the second necrosis or the tie between the soul and the intellect is vermicularly completed by the correlation as twist.

By adhering to *remaining so and as such* as a fitting ontological medium, the One submits to the intension of that which bores through it. Once the Idea of correlation is established, it refracts toward the problematic and is adopted by the Idea of twist. As what necessitates the intervention of nothing, the correlation between solution and problem renders the fate of *being something* entirely problematic. At the same time it makes the destinies of the Ideal, the problem and the solution indeterminable in themselves by factoring in the exteriority of nothing as another determinant to which they have no access and over which they have no influence. Given that the destiny of the Ideal is to survive at all costs, the destiny of the problem is to expose the Ideal and the destiny of the solution is to locate (*chorizein*) an ontological medium that encompasses the problem, the Ideal and the solution. In this regard, correlation-as-twist is also twist-as-destiny (*wyrd*). If the Ideal anticipates the correlation between the solution and the problem, then twist as correlation can also operate under the aegis of the Ideal. Corresponding to the explicit and implicit necroses of the soul and the Etruscan metaphysical cruelty, correlation as twist also operates through two concurrent waves of distortion. The explicit twist of correlation is the Idea of ontology that is generated under the aegis of nothing qua non-belonging or disjunctive exteriority. The implicit twist – more insidious than the first – is the problematic intervention of nothing under the shroud of the ontological medium or the reign of the Ideal. In this sense, the Ideal becomes a necessary excuse to transmit the intention of nothing in the form of the problematic. Whether on the side of the Idea of ontology or that of nothing, the problematic as twist becomes more intricate as each side maintains its position by conforming to the reason that either bilaterally or unilaterally supports it. As the problematic intertwines with reason, it unleashes the problematizing powers inherent to reason as a double-dealer. Once reason and the problematic copulate, the Idea of reason comes forth as that through which nothing can reside outside the pandemonium of the problematic either in supporting itself or the other.

What is at stake here is not reason as glorified tool of disclosure or sponsor of quixotic ventures toward the intellect, but rather the chameleon nature of reason unmasked by the problematic. Bound to the problematic, the animation of reason spawns writhing coils, convolutions, bends and ogees – worms, ratios of putrefaction.

The Idea of survival or the persistence of the remaining characterises the problematic both as the Idea of perforation between the problem and the Ideal, and as the twist between solution and problem. The Ideas of perforation and twist are inherent to the machinery of putrefaction and decay for which remaining less is persistence in remaining, which in turn is insistence upon nothing in the form of the problematic. Only through diminution or intensive decay, which binds survival to the problematic, can the remaining be posited as the solution to the problem of exposing Ideals. Nothing inside the Idea or encompassed by it, can invest itself outside of decay; putrefaction becomes the generative medium of the Idea. In order to be revealed or effectuated, the Ideal must not only remain in itself but must also be bound to decay. The revelation of any truth whatsoever is conducted through decay; but decay is the radically problematic – the Idea. In its intensive and implicit form, decay is problematic intimacy with nothing qua non-belonging; it is the intensive movement of the Idea according to its ontological medium and intention. The Idea of persistence in remaining or persistence in general immanently points to decay as the solution where the continuity of remaining is sponsored by nothing; thereby, the problematic imposes itself regardless of the objective of the ontological medium and its vitalistic impetus. Whether the act of remaining is bound to the intention of the Idea, the Ideal, the problem or the solution, the problematic is enacted. In short, regardless of what shrinkage through remaining entails, the Idea of remaining as such always envelops an encounter with nothing under the heading of the problematic.

MEZENTIUSIAL METAPHYSICS

> The fact is that every living thing among us suffers the torment of Mezentius - that the living perish in the embrace of the dead: and although the vital nature enjoys itself and runs things for a while, the influence of parts nevertheless gets the upper hand not long afterwards, and does so according to the nature of the substance and not at all to the nature of the living one.[10]

The vitalizing forces of the soul move in the direction of two necroses, vectorially opposite but functionally synergistic and collusive. The soul is a bicephalous necrosis. The extensive deployment of the soul through the body is equal to the synthesis of the Idea with that which does not belong to it, while the intensive employment of the soul in itself and according to the intellect is the necessary intention of the Idea. More succinctly, the coupling of the soul with the body is the outward and extensive activity of the Idea and the soul in itself as the activity of the intellect is the inward or intensive activity of the Idea. The outward activity of the Idea is marked by contingency, yet its inward activity is defined by necessity. Only through the two necroses can the necessary and contingent activities of the soul or the Idea be correlated to each other. In the same way, the creativity of the Idea, as correlation between its contingent / extensive and necessary / intensive activities, is only possible through the two necroses. The first necrosis couples the Idea (X) with that which does not belong to it (not-X) in order to extend it beyond itself; it is caused by the profit-seeking or economical openness of X to not-X. The second necrosis, the persistence of the Idea or the progress in the direction of proper perfection by virtue of imposing the primacy and priority of nothing; it is entailed by the survival of X or the possibility of the Idea in its temporal continuation. The Idea in its creativity is the distance between survival and openness. By openness we mean the extensive deployment of the Idea according to that which does not belong to it; by survival, the intensive employment of the Idea according to its ontological medium or its proper objective. Whilst establishing continuity between openness and survival, this distance also posits a subtractive correlation between them.

---

[10] Francis Bacon, *De Vijs Mortis*, VI 357.

By virtue of this distance, openness and survival, the first and the second necroses negatively reinforce and contribute to each other. Through this distance or subtractive space, investment in openness contributes to survival or remaining which, simultaneously, coincides with diminution (remaining less) and closure (remaining in itself). Conversely, the immersion in survival is a contribution to openness, yet it is openness in terms of that which does not belong to the Idea (not-X) or is not the subject of its survival. Creativity is therefore the *art of ratios*[11] between openness and survival, or to be exact, between the first and second necroses. The subtractive space or the distance between openness and survival maintains the Idea between two necroses; but even the two necroses have to encompass this space to reinforce each other. The subtractive space between openness to the body and remaining according to the intellect is defined as the *third necrosis*; for it is the space where only death can enter and death is the only outcome.

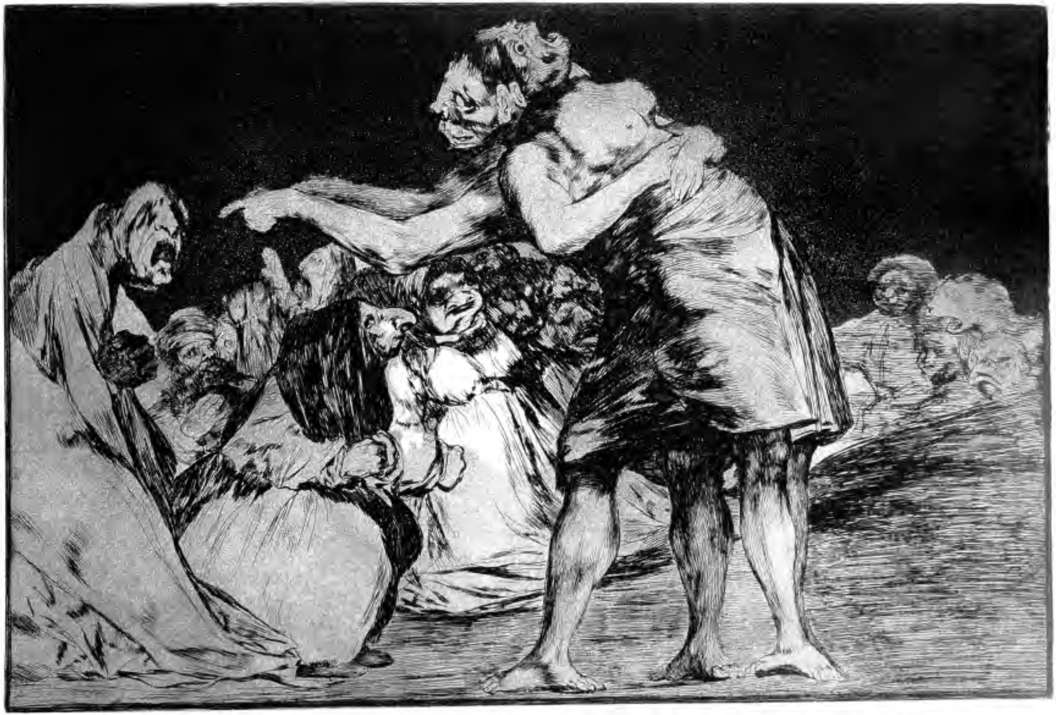
---

[11] Here, the word 'art' is employed in its Lullian connotation.

The third necrosis of the soul or the Idea simultaneously binds and unbinds the first and the second necroses; it is the effectuation of correlation as subtraction or the impossibility of addition. The third necrosis is the *vinculum of doom*, the bond through which every contribution, every investment and every impetus is subtractively – and not additively – engendered. Change through subtraction, or the mobilization of extensive and intensive vectors in regard to each other, is the very Idea of decay.

In its gradation (step-by-step movement) between the body, the soul and the intellect, reason aligns with three necroses; the truth it confirms is predominantly determined by the ternary logic of three deaths. More gravely, with regard to the connection between reason and truth, whatever necrosis reason invokes, the two other necroses will join the gathering. One should not forget that the three necroses of the soul are firmly fastened to each other in the same way that the three necroses of the Idea are subtractively tied together. Accordingly, for reason, there is always a crowd of deaths. The movement of reason is the enumeration or counting of these deaths. The first, second and third necroses, at poles and their in-between: 'It is strange', Reason shrugs; 'all roads lead to the bosom of the dead.'

Fig. 2 (Facing Page): Goya's *Disparates* plate no. 7, The 'Matrimonial' – or, according to a trial proof, 'Disordered' – Disparate (folly, nightmare) introduces a curious adaptation of Andrea Alciato's emblem regarding marriage by force to a corpse or a man seared with syphilitic scabs. In Goya's depiction, the coupling of the living with a putrid corpse is already a fiendish redundancy, for the supposed living cannot come into being other than by being fixed upon a phantom rotting double. When the implicit necrosis of the living is extended to the explicit necrosis of the dead, it begets a nonhuman deformity, a quadrupedal necrosis each of whose four legs – now two – have already been amalgamated by putrefaction.



"I Can See"

Poems[1]

Michel Houellebecq

---

[1] Selected from *Le sens du combat* (Paris: Flammarion, 1996) and *La Poursuite du Bonheur* (Paris: Flammarion, 1997).

A LIFE, SMALL

I felt old very soon after my birth;
Others struggled, desired, sighed;
I felt within myself only a vague regret.
I never had anything resembling a childhood.

Deep in some woods, on a carpet of moss,
Foetid tree trunks survive their leaves;
Around them develops an atmosphere of mourning;
Their skin filthy and black, mushrooms pushing through it.

I have never been any use for anything or to anyone;
A shame – one lives badly when one lives only for oneself.
The slightest movement constitutes a problem,
One feels unhappy and yet generic.

One is obscurely driven, like an animalcule;
Reduced almost to nothing, and yet how one suffers!
Carrying along a sort of void
Portable and petty, vaguely ridiculous.

One no longer sees death as a tragic event;
Mostly on principle, from time to time, one laughs;
One tries vainly to accede to contempt.
Then we accept all, and death does the rest.

I love those hospitals, asylums of suffering
Where the elderly, forgotten, slowly turn into organs
Beneath the gazes, mocking and full of indifference
Of junior doctors who scratch themselves, eating bananas.

In their hygienic but nonetheless sordid rooms
You can easily divine the nothingness that stalks them
Especially when, in the morning, they sit up, livid,
And plead with a whine for their first cigarette.

The old know how to weep with a minimum of sound,
They forget thoughts and they forget gestures
They no longer laugh much, and all that remains of them
At the end of a few months, before the final phase,

Are a few phrases, almost always the same:
Thank you I am not hungry my son is coming on Sunday.
I can feel my intestines, my son will come all the same.
And the son is not there, and their hands almost white.

So many hearts have beaten, already, upon this earth
And the little objects curled up in their cupboards
Recount the sinister and lamentable story
Of those who had no love upon this earth.

The crockery of old bachelors,
The tarnished cutlery of the war-widow
My god! And the handkerchiefs of old spinsters
The insides of cupboards, how cruel life is!

The objects all arranged and life all empty
And the evening meals, the grocers' leftovers
TV unwatched, repast without appetite.

Finally illness, making everything more sordid,
And the tired body that mingles with the earth,
The never-loved body that fades away without mystery.

At the age of seventeen, my sister was very ugly,
In eighth grade they called her double-fatty.
One November morning she jumped in the lake;
But they fished her out; the water was yellow and troubled.

Curled up under the bedspread like an great obese rat,
She dreamt of a serene and barely-conscious life
With no social relations and no hope of a screw,
But tranquil, so gentle, almost evanescent.

The next morning she perceived forms,
Light and fleeting, on the wall to her right.
She said stay with me, I must not sleep;
I see a great Jesus, in the distance, he's limping.

She said I'm a little scared, but it couldn't be any worse.
Do you think he'll come back? I'll put on a blouse.
I can see little houses, there's a whole village;
It's so lovely, down there. Is it going to hurt?

COLLAPSE IV

Death is so difficult for old ladies who are too rich
Surrounded by daughters-in-law who call her “sweetie”,
Pressing a silken handkerchief to their magnificent eyes,
Evaluating the paintings and the antique furniture.

I prefer the death of those old people in the tower-blocks
Who still imagine right to the end that they are loved,
Awaiting the arrival of hypothetical sons
Who will pay for a coffin in real fir.

The old, too-rich ladies end up in the cemetery,
Surrounded by cypresses and plastic shrubs
A nice promenade for sexagenarians,
The cypresses smell good and keep away the mosquitoes.

The old people in the tower-blocks end up at the crematorium,
In a little case with a white label.
The building is calm; no-one, even on Sundays,
Disturbs the sleep of the very old black janitor.

Where is my subtle body? I feel the night coming on,
Pricked with needles and electric shocks
Noises come from far away into a confined space:
The rumbling city, anecdotal machine.

Tomorrow I'll go out, I'll leave my room,
I'll walk, worn-out, on a dead boulevard,
Summer women, their bodies that arch and curve
Will be renewed amidst fastidious decor.

Tomorrow there will be *salades auvergnates*
In bustling cafés where managers chew;
Today is Sunday. May the splendour of God reign!
I just bought myself a rubber doll.

And I see bloody stars flying
I see punctured eyes sliding across the walls;
Mary, mother of God, protect my child!
The night clambers onto me like an unclean beast.

At the corner of FNAC a crowd simmers
Very dense and very cruel
A huge dog chews the body of a white pigeon.
Further away, in the alley,
An old homeless woman curled up into a ball
Is spat on by kids without speaking a word.

I was alone, rue de Rennes. Electric signs
Directed me along vaguely erotic paths.
Hi it's Amandine.
I felt nothing in my prick.
A few yobs passed a menacing gaze
Over the rich girls and the salacious shows.
The managers consume. It is their only function.
And you were not there. I love you, Véronique.

NATURE

I have no time for those pompous imbeciles
Who go into ecstasies before bunnies' burrows
Because nature is ugly, tedious and hostile;
It has no message to transmit to humans.

How pleasant, at the wheel of a powerful Mercedes,
To drive through solitary and grandiose places;
Subtly manipulating the gearstick.
You dominate the hills, the rivers, and all things.

The forests, so close, glitter in the sun
And seem to reflect ancient knowledges;
In the depths of their valleys must lie such marvels,
After a few hours you are taken in;

Leaving the car, the irritations begin;
You stumble into the middle of a repugnant mess,
An abject universe, deprived of all meaning
Made of stones and brambles, flies and snakes.

You miss the parking-lots and the smell of petrol,
The serene, gentle glint of the nickel counters;
It's too late. It's too cold. The night begins.
The forest enfolds you in its cruel dream.

HYPERMARKET – NOVEMBER

Firstly I stumbled into a freezer
I started to cry and I felt a little afraid.
Someone grumbled that I was spoiling the atmosphere;
To retain an air of normality I carried on.

Commuters, drained, with brutal gaze
Walked up and down slowly near the mineral water,
A rumour of the circus and of semi-vice
Mounted from the shelves. My gait was clumsy.

I collapsed at the cheese counter;
There were two old ladies carrying sardines.
The first turned and said to her neighbour:
“It’s really sad, though, a boy of that age.”

And then I saw very broad, circumspect feet;
There was a salesman who took measurements.
Many seemed surprised by my new shoes;
For the last time I was a little on the margins.

END OF THE EVENING

At the end of the evening, the rise of despair is an inevitable phenomenon. There is a kind of timetable of horror. Well, I don't know; I think so.

The expansion of the internal void. That's what it is. A taking-flight of every possible event. As if you were suspended in the void, equidistant from every real action, by monstrously powerful magnetic forces.

Thus suspended, incapable of any concrete grip on the world, the night can seem so long to you. And, indeed, it will be.

It will be, however, a protected night; but you will not appreciate this protection. You will only appreciate it later, once you return to the city, once you return to the day, once you return to the world.

Around nine'o'clock, the world will already have attained its full level of activity. It will turn smoothly, with a gentle whirring. You will have to take part in it, to jump in – a little as if one jumped onto the footplate of a shuddering train ready to leave the station.

You don't make it. Once more, you await the night – which, however, once more, will bring you exhaustion, uncertainty and horror.

And this will happen again, every day, until the end of the world.

The Shadow of a Puppet Dance: Metzinger, Ligotti and the Illusion of Selfhood

James Trafford

There are no people, nothing at all like that.
Thomas Ligotti

No such things as selves exist in the world:
Nobody ever was *or* had *a self.*
Thomas Metzinger

I. BEING NO-ONE

In his *Being No-One*,[1] Thomas Metzinger sets out a radical challenge to any philosophical defence of the status of subjective self-consciousness against the incursions of reductive neuroscience. Deploying all the resources of a nascent science of consciousness, Metzinger proposes at a stroke to eliminate selves from the ontological horizon and to destroy our most cherished 'originary' intuitions about 'ourselves' and our place in the world. Such intuitions furnish the precondition for the phenomenological description of the world that distinguishes between natural, manifest appearances and the supervening artifices of theoretical knowledge. By staking out a supposedly 'unobjectifiable' domain of subjectivity, philosophy has sought to maintain its distance from the coruscating potency of neuroscience. Husserl's so-called 'principle of all principles' provides perhaps the most radical expression of this kind of philosophical presupposition: 'that every originary, presentive intuition is a legitimising source of cognition, that everything originarily offered to us in "intuition" is to be accepted simply as what it is presented as being, but also only within the limits in which it is presented'.[2] But it is precisely the legitimacy of such 'pre-theoretical' intuitions that Metzinger problematises, on the grounds that even appearances themselves are never immediately 'manifest' to the conscious subject who experiences them. Working across several levels of explanation, Metzinger is not only able to draw out a tractable science of consciousness, but to expose consciousness' 'naive realism' about its own states.

Despite formidable technical complexity, the upshot of Metzinger's analyses could not be more clear: 'no such things as selves exist in the world: Nobody ever *was* or *had* a self'.[3] Consequently, 'consciousness is *only* appearance'.[4]

(The Hague: Martinus Nijhoff, 1982), 44. This is concurrent with Husserl's call to get 'back to the things themselves, questioning them in their self-givenness, and laying aside all prejudices alien to them.' (Husserl, *Ideas* I section 19)

[3] Metzinger, *Being No One*, 1.

[4] T. Metzinger, 'Appearance is Not Knowledge: The Incoherent Strawman, Content-

According to Metzinger, organisms are not selves; rather, they possess 'self-models' which cannot be recognised by the system that employs them. All that exist are specific information processing systems engaged in self-modelling, but whose models cannot be correlated with any ostensibly 'real' items in the world. Metzinger thereby eliminates substantive subjectivity in favour not of reduction as such, but of tractable explanation. Rather than reducing the self, he uses the scientific resources at his command to produce a functional model of what 'selves' must be: 'The phenomenal self is not a thing, but a process – and the subjective experience of *being someone* emerges if a conscious information processing system operates under a transparent self-model.'[5]

Expanding upon Wilfred Sellar's attack on the 'Myth of the Given' – 'the idea that some of our beliefs or claims have a privileged epistemic status because the facts that make them true are "given" to us by experience'[6] – Metzinger claims that our folk-philosophical intuitions are a direct result of the bounds of our cognition, as expressed in the limitations of our phenomenal state-space. He illustrates this with a naturalist substantiation of Plato's allegory of the cave, predicated on the argument that 'our phenomenal model of reality is an internal model of reality that could, at any time, in principle, turn out to be quite far removed from a much more high-dimensional physical reality

than we have ever thought of'.[7] The 'cave' is the physical organism; the shadows, a 'low-dimensional projection of a higher dimensional object'; the fire is neural dynamics, i.e. the 'self-regulating flow of neural information processing'; the wall is the space of phenomenology, though the wall and fire are not separate entities. In sum, '[t]he cave in which we live our conscious life is formed by our global, phenomenal model of reality.'[8] In line with some of the bolder suggestions proposed by contemporary physicists,[9] then, Metzinger's analogy proposes that phenomenological perception may well be imprisoned within a virtual model, in which an experienced object is merely a 'low-dimensional shadow of the actual physical object in your hands, a dancing shadow in your central nervous system'.[10] The crucial and far-reaching difference from Plato's cave, however, is that this illusion is, quite literally, *no-one's* illusion: 'there is no-one *in* the cave [...] The cave shadow is there. The cave itself is empty.'[11]

In the following, we will use speculative theses implied by Thomas Ligotti's suffocating, hallucinogenic horror[12] to draw out some of the ramifications of Metzinger's theses. Our fundamental contention is that, just as the expropriation of subjectivity which is the fundamental theme of Ligotti's fiction finds an unexpected realist basis in Metzinger's philosophical naturalism, so, conversely, Ligotti's own metaphysical 'irrealism' affords resources through which the 'unimaginable' consequences of Metzinger's naturalistic 'nemocentrism' can be brought into speculative focus.[13]

[7] Metzinger, *Being No One*, 548.

[8] Ibid., 546.

[9] See, for example, the postulation of extra dimensions of space-time in superstring theory, about which physicist Brian Greene writes that: 'the discovery of extra dimensions would show that the entirety of human experience had left us completely unaware of a basic and essential aspect of the universe. It would forcefully argue that even those features of the cosmos that we have thought to be readily accessible to human senses need not be' (B. Greene, *The Elegant Universe: Space, Time and the Texture of Reality* (London: Penguin Science, 2005), 19.

[10] Metzinger, *Being No One*, 548-9.

[11] Ibid., 549-50.

[12] Very briefly, Ligotti's horror is characterised by a claustrophobic discrepancy between realism and oneirism, in which the world is illusional, and the real inconsistent

II. PHENOMENOLOGY AND THE FICTION OF EXPERIENCE

Metzinger argues that neuroscience circumvents the supposedly irreducible ambit of self-consciousness and dissolves self-intimacy through the objectivation of the mechanisms of subjectivity. It is the non-intuitability of these mechanisms themselves that gives rise to qualitative experience – an experience which is thus constituted by its very inability to access the impersonal mechanisms which make the phenomenal simulation of self possible. This phenomenal simulation is *transparent* to experience: 'we do

---

and autonomous. Hence, Ligotti inverts the very possibility of redemption: The close-ness of world is disclosed in grotesque fabulation to be utterly autonomous in exactly the same moment as it is revealed that the mind is equally autonomous from the normative phenomenal experience of man. See, for example, T. Ligotti, *Crampton* (Poplar Bluff, MO: Mythos Books, 2002); T. Ligotti, 'I Have a Special Plan For This World' in *Teatro Grotesco* (London: Random House, 2008); T. Ligotti, 'Mad Night of Atonement' in *Noctuary* (New York: Carroll and Graf, 1994); T. Ligotti, 'The Tsalal' in *Noctuary* (New York: Carroll and Graf, 1994); and T. Ligotti, 'The Sect of the Idiot' in *Songs of a Dead Dreamer* (London: Robinson Publishing, 1989).

[13] 'A nemocentric reality model is one that satisfies a sufficiently rich set of constraints for conscious experience [...] while at the same time not exemplifying phenomenal selfhood. It may be functionally egocentric, but it is phenomenologically selfless. It would, while still being a functionally centred representational structure, not be accompanied by the phenomenal experience of being *someone*.' (Metzinger, *Being No One*, 336). Nemocentricism, for Metzinger, is a phenomenologically unimaginable possibility; however, it is a possibility that is perfectly conceivable and neurobiologically possible (see Metzinger, *Being No One*, op.cit.).

not experience phenomenal states *as* phenomenal states […] [we] *look through them*'.[14] Metzinger regularly alludes to fully immersive virtual reality to illustrate his thesis: 'We do not experience our conscious field as a cyberspace generated by our brain, but simply as reality itself, with which we are in contact in a natural and unproblematic way.'[15] Folk psychology's agenda is driven by a first person logic, occupying a perspectival and geometric structure that is temporally and spatially individuated.[16] This first-person perspective, however, is simply the phenomenal self-model, which Metzinger considers amenable to a neurobiological description, most likely involving parallel distributed processing (PDP), and a functional description: 'the phenomenal self-model is a plastic, multimodal structure'.[17]

First-person phenomenal experience is thus formulated as an empirical ideality, an empty fiction that is plastic, and therefore highly dependent upon the idiosyncrasies of the species. Effectively, the first-person perspective is a generation of worldhood, 'a *phenomenal* cosmology'.[18] The layers of simulation that coalesce into phenomenal experience encapsulate the intuition of phenomenal cosmology which, from the third person perspective, is understood to be a representational and functional property which can be analysed *in its entirety* on this basis.[19] 'Selves' in the full-blooded ontological sense, then, fall victim to Ockham's razor:

---

[14] T. Metzinger, 'The Problem of Consciousness' in *Conscious Experience*, ed. T. Metzinger (Thorverton, UK: Imprint Academic, 1995) 11.

[15] **Ibid.**, *11.*

[16] Folk psychology attributes a unique and direct causal link from a selection process for volition as the cause of behaviour. Metzinger takes this causal link to be untenable, so that; 'it is not only that folk psychology is false - it is the content of the conscious self-model that attributes a causal relation between two events represented within it' (Metzinger, *Being No One*, 360). Folk psychology is therefore both false and hallucinatory from a scientific, third person account.

[17] T. Metzinger and B. Walde, 'Commentary on Jakab's "Ineffability of Qualia", *Consciousness and Cognition* 9 (2000), 352-62.

[18] Metzinger, 'The Problem of Consciousness', 6.

> Under a general principle of ontological parsimony, it is not necessary (or rational) to assume the existence of selves, because as theoretical entities they fulfil no indispensable explanatory function [...] All that can be explained by the phenomenological notion of a 'self' can also be explained using the representationalist notion of a transparent self-*model*.[20]

Even the most elementary components of phenomenality are unavailable to the self. For example, Metzinger argues that, in order to draw logical concepts from phenomenal content, and therefore to have epistemic and justified belief with regard to simple forms of phenomenal content, transtemporal identity criteria would have to be assumed, drawn directly from material identity criteria.[21] In that case, the abstraction of logic or ontology from experience would necessitate the indubitability of the self-manifestation of appearances: 'letting apparition show *itself* in its appearance according to its appearance'.[22] Thus, phenomenological appearance is rooted in an originary field of self-identity which, removing the imposition of the conceptual a priori, claims to return 'things' to lived experience, and to the fleshly actuality of consciousness. According to Metzinger, we only assume the reliability of this primitive self-identity on the assumption that 'in our subjective experience of sensory sameness we carry out a phenomenal representation of this transtemporal identity on the object level in an automatic manner, which already carries its epistemic justification in itself.' – and '[i]t is precisely this background assumption which is false'.[23] The transtemporal criteria necessary for the subjective individuation and consequent logical identity are simply unavailable to subjective introspection, so that phenomenal concepts are a priori incapable of being introspectively formed. Phenomenological primitives, supposedly straightforwardly given to the conscious subject, are incapable of providing even the most basic conceptual traction on the data of consciousness. Hence, as Metzinger argues:

---

[19] See Metzinger, *Being No One*, 577. However, Metzinger suggests that this might not be a rational choice in all contexts, drawing a clear distinction between his work and the Churchlands'.

[20] Ibid.

[21] For a phenomenological account in which this is indeed assumed to be the case, see J-L. Marion, *Being Given: Toward a Phenomenology of Givenness*, trans. J. Kosky (Palo Alto, CA: Stanford University Press, 2002) 7ff.

[22] Ibid., *8*.

> The phenomenological approach in philosophy of mind, at least with regard to those simple forms of phenomenal content, is due to failure; a descriptive psychology cannot come into existence with regard to almost all of the most simple forms of phenomenal content […] The neural and functional correlates of the corresponding phenomenal states can, in principle, provide us with transtemporal identity criteria as well as with those logical identity criteria for which we have been looking. Neurophenomenology is possible; phenomenology is impossible.[24]

Only through the objective scientific circumvention of self-conscious experience is it possible to gain traction on the specific reality of both the manifest and non-manifest elements of phenomenal consciousness.

---

[23] Metzinger, *Being No One*, 82.

[24] Metzinger, 'Commentary on Jakab's "Ineffability of Qualia"'.

III. TRANSPARENCY: A SPECIAL FORM OF DARKNESS

The phenomenal self comes about through a 'special form of epistemic darkness' – essentially, the inability of the subject to represent the conditions of its own intuitions. Folk psychology posits that the world is given immediately to subjective consciousness; it assumes that the experience of phenomenal content is transparent to the self. Metzinger argues, on the contrary, that immediacy is an illusory experience of the 'outside' world:

> From an epistemological perspective, we see that our phenomenal states at no point in time establish a direct and immediate contact with the world for us […] However, on the level of phenomenal representation […] this fact is systematically suppressed.[25]

In a direct inversion of the traditional notion of the transparency of inner sense, Metzinger argues that transparency, as an essential characteristic of phenomenal experience, illuminates the phenomenological fallacy of *pure* experience and the 'subjective impression of immediacy'. Naive realism is not, therefore, a philosophical theory as such; it is the global character of intuition, once the latter is understood in terms of phenomenal content locally supervening on neurobiological properties. Opacity, as opposed to transparency, occurs when appearances are cognised *as* appearances. Hence, our primitive pre-reflective feeling of conscious selfhood is *never* truthful, in that it does not correspond to any single entity *inside* or *outside* of the self-representing system.[26] The culmination of this inversion of the concept of transparency is indicated by the fact that transparency is a form of darkness: 'With regard to the phenomenology of visual experience transparency means that we are not able to see something, because it is transparent. We don't see the window but only the bird flying by. *Phenomenal* transparency in general, however, means that something particular is not accessible to subjective experience, namely, the representational character of the contents of conscious experience.'[27] The immediately given contents of the Phenomenal Self-Model (PSM) correspond neither to the sub-personal mechanisms underlying those contents, nor to any kind of external reality; the entire life-world is illusory, an 'online hallucination'.[28] Metzinger calls this feature of the self-model theory (SMT) 'autoepistemic closure' – that is, the closure and boundedness of processing in regard to internal dynamics. Autoepistemic closure allows for the availability of phenomenal content but not of the vehicle of content.[29]

---

[25] Metzinger, *Being No-One,* 59.

---

[26] See ibid., 565.

[27] *Ibid.,* 169. Metzinger elucidates this point: 'We do not have the feeling of living in a three-dimensional film or in an inner representational space: in standard situations our conscious life always takes place *in the world*. We do not experience our conscious field as a cyberspace generated by our brain, but simply as reality itself, with which we are in contact in a natural and unproblematic way. In standard situations the contents of pure experience are subjectively given in a direct and seemingly immediate manner. It is precisely in this sense that we can say: they are infinitely close to us.' (Metzinger, 'The Problem of Consciousness' , 11-2).

[28] See Metzinger, *Being No-One*, 51. As Metzinger puts it: 'The instruments of representation themselves cannot be represented as such anymore, and hence the experiencing system, by necessity, is entangled in a naive realism.' (Ibid., 169).

[29] The dualism of vehicle and content is not available for Metzinger; they cannot be understood as two distinct entities (see Metzinger, *Being No-One*, 166). More specifically then, transparency results from the: 'attentional unavailability of earlier processing stages in the brain for introspection. Transparency results from a structural / architectonic property of the neural information-processing going on in our brains' (T. Metzinger, 'Phenomenal Transparency and Cognitive Self-Reference',

However, as Metzinger is unwilling to split vehicle from content – which he believes would reify abstract content – transparency is further complexified by the assumption that there is a processual and physically realised *embodied* content.[30] Metzinger therefore effectively lays waste to functionalism's attempt to abstract the cognitive from actual physiological processes, an attempt which arguably already concedes the irreducible status of human sapience *vis-à-vis* its empirical substrate.

This, of course, is a characteristically modern philosophical distinction – the same one that allows Kant to maintain the autonomy of the transcendental subject from any empirical intervention or knowledge whatsoever. Through the *Critique of Pure Reason*'s so-called 'paradox of inner sense', Kant is able to maintain the transcendental status of the 'I think' without lapsing into pure idealism, which would necessarily conflate inner sense with consciousness.[31] Inner and outer sense are given in empirical perception as an intuitive whole, which is ultimately determined by the understanding through the transcendental synthesis of pure apperception.[32] Therefore, the intuitive unity of subjective consciousness remains distinct from the transcendental

---

Phenomenology and the Cognitive Sciences 2 (2003), 353–93.

[30] Hence, phenomenal transparency is distinguished from a Cartesian epistemic transparency; 'The Cartesian claim about the epistemic transparency of self-consciousness can itself not be epistemically justified.' (Metzinger, *Being No-One*, 167), though it is phenomenologically adequate (see Metzinger, *Being No-One*, 340).

[31] This is key to Kant's critique of idealism and of the Cartesian subject; that they conflate inner sense with the conscious self.

[32] Kant argues that: 'What determines inner sense is the understanding and its originary power of combining the manifold of intuition, that is, of bringing it under an apperception.' I. Kant, *Critique of Pure Reason*, trans. Meiklejohn, ed. V. Politis (London: Everyman, 1993), 111 (B153).

unity of apperception, the ‘I think’, that unifies the manifold of presentations into an object of experience.

Metzinger concurs with Kant on the futile nature of rational psychology, and similarly on his transcendental (rather than ontological) distinction between phenomenal content and reality. However, this transcendental *opacity*, for Kant, lies in the fact that there can be no transparent knowledge of the self – concomitant with which is the dissolution of the substantive self through the positing of a formal a priori ground of subjectivity. Hence, whilst Kant’s concept of ‘transcendental illusion’ certainly corresponds with what Metzinger terms ‘phenomenological illusion’ – that is, the drawing of epistemic conclusions from phenomenal experience -- ultimately, Kant’s positing of a noumenal subjectivity commits the same fallacy that he had sworn to abjure. For, if Metzinger is correct, then the PSM undermines any attempt to transcendentalise subjectivity or consciousness, and the putatively noumenal substratum of inner sense can be cashed out in its entirety from within the ambit of scientific objectivity. Kant presupposed the unification of sense to be given through the unity of apperception that acts as the transcendental guarantor for the nomological consistency of appearances, and thus specifies ideal laws of appearance that have subsequently been shown to be rooted in empirical intuition. Metzinger disavows the role of syntactical invariance through his insistence on the sub-symbolic and immanent objectivity of the non-manifest element of consciousness.[33] The self-model is a

---

[33] As Metzinger explicates: ‘the presence and striking holism of phenomenal reality […] would no longer have to be explained in accordance with classical philosophical models *from* above (e.g. by a transcendental subject), if we had a good bottom-up alternative […] called “feature binding” in the terminology of brain research: The fusion of different properties perceived by the system into a *holistic* internal structure.

plastic structure which can be neurobiologically described as a complex neural activation pattern. But furthermore, '[o]n a more abstract level the same pattern of physiological activity can also be described as a complex functional state'.[34] Since appearances are not discursively structured for Metzinger, he eradicates the autonomy of nomological consistency by rooting the manifestation of appearances in physical structures that are in no way dependent upon ideal (transcendental) laws.

Metzinger thus inverts Kantian 'opacity', arguing that it is not the transcendental opacity of the self that is primary, but the transparency of the self-model, which, through its objectivation, can become opaque, allowing for the cognising of appearances *as* appearances. It is our functional design that forces us into a naive realism, so that the explanation for semantic transparency is given by an evolutionary, rather than a transcendental, account: 'for biological systems like ourselves – who always had to minimise the computational load [...] naive realism was a functionally adequate "background assumption" to achieve reproductive success [...] [there was] no evolutionary pressure on our representational architecture to overcome the naive realism inherent in semantic transparency'.[35]

Such a binding of properties is, for instance, necessary in enabling us to see objects *as* objects' (Metzinger, 'Faster than Thought: Holism, Homogeneity and Temporal Coding', in *Conscious Experience*, ed. T. Metzinger (Thorverton, UK: Imprint Academic, 1995), 435.

[34] T. Metzinger, 'The Subjectivity of Subjective Experience: A Representationalist Analysis of the First-Person Perspective' in *Neural Correlates of Consciousness: Empirical and Conceptual Questions*, ed. T. Metzinger (Cambridge, MA: MIT Press, 2000), 289.

[35] Metzinger, *The Subjectivity of Subjective Experience*, 299.

IV. THE IMMANENT OBJECTIVATION OF CONSCIOUSNESS

Kant safeguards the autonomy of philosophy via recourse to a notion of an a priori transcendental subjectivity which would circumscribe possible experience, rendering empirical science inherently incapable of investigating the objectivity of the object and the formal conditions of empirical actuality. And, whether overtly or not, much 'continental philosophy' remains wedded to the presupposition that science is supervenient on a set of concepts that are ideally embedded in the subject. This disjunction of the empirical sciences and philosophy arguably attains its most extreme formulation in Husserl's conception of pure phenomenology as a transcendental-eidetic science whose bracketing of the world ensures that the natural sciences are confined to *res extensa*, thereby preserving an immanent plane of pure experience governed by an irreducible transcendental consciousness: 'the existence of Nature cannot be the condition for the existence of consciousness, since Nature itself turns out to be a correlate of consciousness: Nature is only as being constituted in regular concatenations of consciousness'.[36] However, according to Metzinger, it is the very domain of pre-theoretical access which, despite all claims to the contrary, is ultimately tethered to the myopia of contingently – evolutionarily – circumscribed conditions of intuition. Phenomenology, rather than reaching into 'the things themselves', succeeds only in transcendentalising folk psychology. In the wake of Metzinger, consciousness must be conceived of as produced by immanent objective mechanisms, which are themselves sub-symbolic, non-linguistic, and unconscious, so that 'pure self-reflection' is exposed as caught within the obscurantism of an empirico-transcendental circularity.

---

[36] E. Husserl, *Ideas*, Book 1, 116. See also Husserl's account of phenomenology as an eidetic science: 'phenomenological or pure psychology as an intrinsically primary and completely self-contained psychological discipline, which is also sharply separated from natural science, is, for very fundamental reasons, not to be established as an empirical science but rather as a purely rational ("apriori," "eidetic") science. As such it is the necessary foundation for any rigorous empirical science dealing with the laws of the psychic, quite the same way that the purely rational disciplines of nature pure geometry, kinematics, chronology, mechanics are the foundation for every possible "exact" empirical science of nature' (Husserl, 'Phenomenology: Entry for the Encyclopedia Britannica', *Journal of the British Society for Phenomenology* 2, 1971: 77-90.

Metzinger argues that where philosophy has long grappled with reason and representation, it is only now that representation has 'through its semantic coupling with the concept of information, been transposed to the domain of mathematical precision and subsequently achieved empirical anchorage'.[37] Thus, '[c]onceptual progress by a combination of philosophy and empirical research programs is possible; conceptual progress by introspection alone is impossible in principle'.[38] Metzinger's work constantly forces philosophy to take account of *objective* intelligence; the sub-personal production of phenomenality as a naturalised Kantianism. The objective structure of knowledge is invested with empirical contingency, as one among many objective procedures; man as a mass of info-theoretic computation packed densely through sedimented layers of transcendental deception.

V. NEMOCENTRISM

Perhaps one of the most intriguing undercurrents of Metzinger's book, albeit one that he does not expand upon, is the implicit suggestion that the interests of thought can be unbound from lived experience, and in many cases even opposed to the interests of life.[39] For example, in a general discussion of scientific realism, Metzinger writes that 'there are aspects of the scientific world-view which may be damaging to our mental well-being'.[40] The object 'man' consists of tightly packed layers of simulation, for which naive realism becomes a necessary prophylactic in order to ward off the terror concomitant with the destruction of our intuitions regarding ourselves and our status in the world: 'conscious subjectivity is the case in which a single organism has learned to enslave *itself*'.[41] It is at this point that Thomas Ligotti's work can illuminate Metzinger's thesis, offering a phenomenological purchase upon that which Metzinger has claimed to be impossible for the imagination – methodological nemocentrism.

---

[37] Metzinger, *Being No One*, 19.

[38] *Ibid.,* 83.

Ligotti invokes the expropriation of subjective experience thus: 'There are no people, nothing at all like that, the human phenomenon is but the sum of densely coiled layers of illusion, each of which winds itself upon the supreme insanity that there are persons of any kind.'[42] Ligotti couples this supreme insanity with a metaphysical irrealism regarding the substantive nature of the world. The supposedly foundational order of the phenomenal world is a mere semblance – and not a semblance of a supra-terrestrial realm, or an alien 'Other', but a semblance of the real world, which is utterly indifferent to the interests of organic life and thought. Ligotti thus unfolds some of the existential and phenomenological implications of Metzinger's conceptualisation of the relative autonomy of appearances: His characters experience reality in a way that is utterly incommensurate with the phenomenological register of human perception.

---

[39] This is consistent with our general critique of phenomenology, following Derrida's characterisation of Husserl's work as 'a philosophy of life […] because the source of sense in general is always determined as an act of living, as an act of a living being, as *Lebendigkeit*' (J. Derrida, *Speech and Phenomena and Other Essays on Husserl's Theory of Signs* (Evanston, IL: Northwestern University Press, 1973) 10). On this divorce between the interests of thought and those of life, see Ray Brassier's *Nihil Unbound: Enlightenment and Extinction* (Basingstoke: Palgrave, 2006).

[40] Metzinger, 'Response to "A Self Worth Having"'.

[41] Metzinger, *Being No One*, 558. The self is mere appearance; 'the conscious self is an illusion which is no-one's illusion' (Metzinger, 'The Subjectivity of Subjective Experience', 2000).

[42] Ligotti, 'I Have a Special Plan for this World'.

Ligotti's work is characterised by two movements which he refuses to separate: the subject's passive dispossession of self-consciousness, and the 'enlightenment of inanity'. This double movement unmasks the reality within which the characters have always been. The suffocating effect Ligotti achieves through this process is intensified by his staunch repudiation of any recourse to the supernatural; there is no possibility of escape. Hence, the *ascecis* of the personal takes place within a positively insignificant reality, a realisation which dissolves both the intimacy of subjective experience, and the impersonal distance of the mechanics of that experience.

Ligotti's phenomenological nemocentrism draws out this collapse of any securely demarcated ontological and epistemological foundations in a weird-fictional landscape filled with the ruins and ghosts of puppets. Throughout Ligotti's work, the puppet figures as the insensate and sub-personal reality hidden beneath the 'mindless mirrors' of our naive reality. Puppets function as 'conduits to the unreal',[43] through whose agency hallucinatory phenomenality bleeds into a simultaneous concretisation of the oneiric. Life is played out as an inescapable puppet show, an endless dream in which the puppets are generally unaware that they are trapped within a mesmeric dance of whose mechanisms they know nothing, and over which they have no control. As Dziemianowicz notes in relation to Ligotti's 'Dreams of a Mannikin', the puppet's overriding affect is a suspicion that 'he and his entire world are merely a fictional diversion'.[44] The puppet is not merely an mocking parody of man, it is the unmasking of the animate face of insensate reality, the unveiling of the inexorable mechanics of the personal; 'There are no means for escaping this world. It penetrates even into your sleep and is its substance. You are caught in your own dreaming where there is no space. And are held forever where there is no time. You can do nothing you are not told to do. There is no hope for escape from this dream that was never yours. The very words you speak are only its very words.'[45] The irrepressible horror concomitant with Ligotti's concretisation of the oneiric stems from the *experience* of living in a 'three-dimensional film', a 'tunnel through an inconceivably high-dimensional reality'.[46] This phenomenal experience of nemocentrism ultimately dissolves both the intimacy of the personal and the distance of the impersonal; 'nothing's too small, nothing's too big. You lose your car keys, your wife gets run over by a semi, some nut blows up the capital of Pakistan'.[47] For this reason, the concretisation of the puppet concomitant with the increasing passivity of the narrator engenders an affect of universal claustrophobia through the implosion of the personal – which was, of course, never personal to begin with.

[45] Ligotti, 'I Have a Special Plan for this World'.

[46] Metzinger, *Being No One*, 551.

[47] Ligotti, *Crampton*, 82.

It is resolutely not the case, however, that the puppet-world is 'willed' into existence by an 'Other'; there is no puppet master pulling the strings.[48] Ligotti's systematic assault on empirical realism is not a result of the reinvigoration of the world with a Heraclitean flux, a pure productivity, or a contingent excess of materiality. Ligotti's real is 'positively' senseless, rigorously disabling any attempt to provide reality with substantive or ideal foundations by irreversibly severing its reciprocity with the pretensions of subjective thought. Ligotti can no more assume the existence of an extant and hypostatised nature than he can assume the necessary constancy of presence. The transcendental illusion exposed by Metzinger is expanded into a total disparity between the interests of life and the reality that life finds itself within. The secure foundations of the phenomenal and the real dissolve, not into a universal solipsism, but into a rigorous realism; 'it is not, in the end, a replacement of the real world by the unreal, but a sort of turning the real world inside out to show that it was unreal all along'.[49]

---

[48] As Ligotti consistently maintains, the dissolution of the self cannot give way to a Schopenhaurian Will, as this reinstates some form of 'first philosophy' in the form of an underlying essence. See Ligotti, 'Tsalal'; 'You wrote that there is not true growth or evolution in the life of this world but only transformations of appearance, an incessant melting and molding of surfaces without underlying essence. Above all you pronounced that there is no salvation of any being because no beings exist as such, nothing exists to be saved – everything, everyone exists only to be drawn into the slow and endless swirling of mutations that we may see every second of our lives'.

[49] Joshi, 'Thomas Ligotti', 139. Hence the statement; 'Nothing is real' (Ligotti, *Crampton*, 83), is not assumable under the idealising consequences of phenomenal immediacy.

Where Metzinger definitively resolves to destroy the possibility of the synthesis of man and nature, it is through Ligotti's phenomenological fictionalisation that the affective ramifications of this move are elucidated. Ligotti has developed a method of realising the absolute indifference of the real to the human and the personal through a metaphysical irrealism in which he disentangles appearances from both sufficient reason and originary manifestation by severing the nomological isomorphism of appearances and their substrate; in the end, subjectivity is simply a specific exacerbation of objectivity.[50] Accordingly, an unforeseen consequence of Ligotti's inhabitation of Metzinger's epistemic nemocentricism is that Metzinger's naturalistic realism ends up providing traction on Ligotti's metaphysical irrealism: 'The horror and nothingness of human existence – the cosy facade behind which was only a spinning abyss.'[51] Phenomenal cosmology is not given by a structural syntax, but is simply an exacerbation of objective processes unconstrained by any form of ideality.

---

[50] The dissolution of apodictic realism is continuous with the dissolution of apodictic thought; 'the integrity of material forms is only a prejudice, at most a point of view [...] things are not bolted down, so to speak. And no more is that thing which we call the mind' (T. Ligotti, 'The Cocoons' in *The Shadow at the Bottom of the World* [NY: Cold Spring Press, 2005], 164).

[51] T. Ligotti, *Conspiracy Against the Human Race* (Forthcoming – see extract in present volume). This would entail the extraction of metaphysical naturalism from naturalistic realism, which is methodological rather than ontological. Accordingly, it is possible that naturalism may not be the most promising explanatory ground for Metzinger's self-model theory, as evolutionary ethology can be shown to ground a representational efficacy, but in order to extrapolate scientific realism on this basis, Metzinger would have to argue that nature is inherently functional, and therefore promoting a functional univocity. In this case, Metzinger would succumb to the charges that Stephen J. Gould poses to Daniel Dennett: making 'thinly veiled attempts to smuggle purpose back into biology' (S. J. Gould, *The Richness of Life: A Stephen Jay Gould Reader* [London: Vintage, 2007], 442). See D. Dennett, *Darwin's Dangerous Idea: Evolution and the Meanings of Life* (London: Penguin, 1996).

Ligotti's horror, then, can be understood in terms of Metzinger's theory, in such a way as to grasp Ligotti's work as a fictional realisation of Metzinger's nemocentrism. Ligotti's horror is removed from the realm of the fantastic and given naturalistic traction through Metzinger's definition of man as the 'puppet shadow [that] dances on the wall of the neurophenomenological caveman's phenomenal state space'.[52] Equally, reading Metzinger alongside Ligotti, or as Ligottian theory-horror, accentuates the anomic terror of the arrogation of the self, as the folk psychological ascription of agency that is preserved in the artifice of natural language is extricated from the transcendental pretensions that phenomenology underwrites.

Finally, Ligotti enables us to recognise that the theoretic-practical resolve of Metzinger's theory is to be found not in the reduction of folk psychology, but in a kind of neurotechnology. Phenomenality and knowledge-weighting are malleable: 'the phenomenal self-model is a plastic, multimodal structure'[53] whose 'insertion and integration into other domains of information architecture amplify the potential for cognitive pliability'.[54] What is this but the naturalisation of the final outcome of Ligotti's fantastical puppet-dance: the realisation that underlying our parochial self-conceit is the impersonal reality of the meat-puppet?[55]

---

[52] Metzinger, *Being No One*, 558.

[53] Metzinger, 'The Subjectivity of Subjective Experience', 289.

[54] See Metzinger; 'change the representational content of the conscious self-model […] get some unconscious microfunctional output' (Metzinger, 'Response to "A Self Worth Having"').

[55] The conjunction of Ligotti and Metzinger induces the definition of man as the shadow of a 'meat-puppet'. For a reading of man as a meat-puppet within contemporary science, see R. Doyle, *On Beyond Living: Rhetorical Transformations of the Life Science* (Stanford: Stanford University Press, 1997), 36; see also its fictional realisation in the character of Molly in W. Gibson, *Neuromancer* (London: Voyager, 1984).

Here the objectivation of the world indicates its *real* condition, unveiling the inexorable mechanics of appearances as a prospect of hideous insanity – a hall of mindless mirrors unbound from the densely coiled layers of illusion that characterise the interests of life and the physiology of thought. Meanwhile, cognitive protectionism and organic enslavement ensure the oneiric aphasia of the shadow of the puppet dance:

> To know, to understand in the fullest sense, is to plunge into an enlightenment of inanity, a wintry landscape of memory whose substance is all shadows and a profound awareness of the infinite spaces surrounding us on all sides. Within this space we remain suspended only with the aid of strings that quiver with our hopes and our horrors, and which keep us dangling over the gray void. How is it that we can defend such puppetry, condemning any efforts to strip us of these strings? The reason, one must suppose, is that nothing is more enticing, nothing more vitally idiotic, than our desire to have a name – even if it is the name of a stupid little puppet – and to hold on to this name throughout the long ordeal of our lives, as if we could hold on to it forever. If only we could keep those precious strings from growing frayed and tangled, if only we could keep from falling into an empty sky, we might continue to pass ourselves off under our assumed names and perpetuate our puppet's dance throughout all eternity.[56]

Thinking Horror[1]

Thomas Ligotti

BEGINNINGS

For ages they had been without heads. Headless they lived, and headless they died. How long they had thus flourished none of them knew. Then something began to change. It happened over unremembered generations. The signs of a transfiguring were being writ ever more deeply into them. As their breed moved forward, they began crossing boundaries whose very existence they never suspected ... and they trembled. Some of them eyed their surroundings as they would a strange land into which they had wandered, even though their kind had trodden the same earth for countless seasons. And after nightfall, they looked up at a sky filled with stars and felt themselves small and fragile in the vastness. More and more, they came to know a new way of being. It was as if the objects around them were one thing and they were another. The world was moving farther and farther away, and they were at the center of this movement. Another world was forming inside the heads they now had. Each of them, in time, became frightened in a way they had never known. In former days, they were frightened only by sights and sounds in the moments they saw or heard them. Now they were frightened by things that were not present to their senses. They were also frightened by visions that came not from outside them but from within them. Everything had changed for their kind, and they could never return to what they once had been. The epoch had passed when they and the rest of creation were one and the same. They were beginning to know a world that did not know them. This is what they thought, and they thought it was not right. Something which *should not be* ... had become. And something had to be done if they were to flourish as they had before, if the very ground beneath their feet were not to fall out from under them. They could do nothing about the world which was moving farther and farther away and which knew them not. So something would have to be done about their heads.

---

[1] The present text is an extract from *The Conspiracy Against the Human Race: A Short Life of Horror* (forthcoming), a work which binds together themes from pessimistic philosophy and the horror genre into an exposition on the uncanny nature and ontological fraudulence of the human species.

DIFFERENCES

For centuries a debate has been going on among us, a shadowy polemic that periodically attracts public notice. The issue: what do people think about being alive? Overwhelmingly, those questioned will say, 'Being alive is all right'. More thoughtful respondents will add, 'Especially when you consider the alternative', betraying a jocularity that is as logically puzzling as it is macabre, since the alternative is the first among certitudes that make being alive not

all right. These speakers weigh down one side of the survey. On the other side is a small sample in disagreement with the majority. Their response to the question of what they think about being alive will be a negative one. They may even fulminate about how objectionable it is to be alive. Now, there are really no incisive answers to why people think or feel this way or that. But one thing is sure: the people in the second group are pessimists. And in the minority opinion of pessimists, most of the people in this world have to work very hard to keep from thinking there is anything objectionable about being alive.

Lamentably, we cannot choose to think what we think or feel what we feel. If we did have this degree of mastery over our internal lives, then we would be spared an assortment of sufferings. Psychiatrists would be out of a job as depressives chose to stop being depressed and schizophrenics chose to stop being crazy. Most people, especially those who say that being alive is all right, do believe they have considerable choice in choosing what they think and feel. And psychiatrists, who will never be unemployed, seldom dissuade their clients from believing they can choose their thoughts and feelings. Nevertheless, those who believe they can choose what they think and feel are incapable of *choosing what they choose* to think and feel. Should they still believe themselves in control of what they choose to choose to think and feel, they still could not choose to choose to choose . . . and so on. Were there any choice on our part regarding what we think and feel, it would not be adventurous to conjecture that we would think about pleasant things rather than horrible things and choose to feel good rather than bad. Some might even choose to think about nothing at all and to live in a permanent state of euphoria until they died of natural causes. With godlike power over your thoughts and feelings, you could do as you choose. And who would choose to think horrible thoughts and feel bad feelings about being alive?

ZAPFFE

If the most contemplative individuals are sometimes dubious about the value of existence, they do not often publicize their doubts but align themselves with the man in the street, tacitly declaiming, in more erudite terms, 'Being alive is all right, etc'. The butcher, the baker, and the crushing majority of philosophers all agree on one thing: human life is justified, and we should keep our species going for as long as we can. To tout the opposing side is asking for grief. But some people seem born to bellyache that being alive is not all right. Should they vent this unpopular view in philosophical or literary works, they may do so without apprehension that their efforts will have an excess of admirers. Notable among such efforts is 'The Last Messiah' (1933), an essay written by the Norwegian philosopher and man of letters Peter Wessel Zapffe (1899-1990). In this work, which has been twice translated into English,[2] Zapffe elucidated what he saw as the tragedy of human existence.

---

[2] 'The Last Messiah', *Wisdom in the Open Air: The Norwegian Roots of Deep Ecology* (Minneapolis: Minnesota U. Press, 1993), eds Peter Reed and David Rothenberg (translators Sigmund Kvaløy with Peter Reed); *Philosophy Now*, March-April 2004 (translator Gisle R. Tangenes). Regrettably, Zapffe's philosophical masterwork, *On the Tragic* (1941), has not appeared in any major language at the time of this writing. However, abstracts of its substance, as well as excerpts from this treatise and other writings by Zapffe as translated into English by Tangenes, confirm that throughout his long life he did not abandon or dilute the pessimistic principles of *On the Tragic* as they appear in miniature in 'The Last Messiah'.

Before discussing why Zapffe saw human existence as a tragedy, it may be useful to consider a few facts whose relevance will become manifest down the line. As some may know, there exist readers who treasure philosophical and literary works of a pessimistic, nihilistic, or defeatist nature as indispensable to their existence, hyperbolically speaking. Cynical by nature, these persons are well aware that nothing indispensable to their existence, hyperbolically or literally speaking, must make its way into their lives, as if by natural birthright. They do not think that anything indispensable to anyone's existence may be claimed as a natural birthright, since the birthrights we commonly bandy about are all fictions, something we dreamed up after straying from a factual world into one fabricated by our heads. For those who have given any thought to this matter, the only rights we may exercise are these: to seek the survival of our individual bodies, to create more bodies like our own, and to perish through a process of corruption or mortal trauma. This is presuming that one has been brought to term and has survived to a certain age, neither being a natural birthright. Stringently considered, *our only natural birthright is to die*. No other rights have been allocated to us except, to repeat, as fabrications. The divine right of kings may now be acknowledged as a fabrication, a falsified permit for prideful dementia and impulsive mayhem. The unalienable rights of certain people, however, seemingly remain current: whether observed or violated, somehow we believe they are not fabrications because an old document says they are real. Miserly or munificent as a given right may appear, it denotes no more than the right of way warranted by a traffic light, which does not mean you have the right to drive free of vehicular misadventures. Ask any paramedic.

Our want of any natural birthright – except to die, in most cases without assistance – is not a matter of tragedy but only one of truth. Coming at last to the pith of Zapffe's thought as spelled out in 'The Last Messiah', the tragedy of human existence had its beginnings when at some stage in our evolution we somehow acquired consciousness. Zapffe believed consciousness to be a mistake in human evolution, an adventitious outgrowth that made of us a race of monsters – things that had nothing to do with the rest of creation. Because of consciousness, we became susceptible to thoughts that were startling and dreadful to us. ('I think, therefore I am and will one day die', or thus might have read René Descartes' formulation had he gone the whole mile with it). Our heads now began dredging up horrors, flagrantly joyless possibilities, enough of them to make us drop to the ground in paroxysms of self-soiling consternation should they go untrammeled. This potentiality necessitated that certain defense mechanisms be put to use to keep us balanced on the knife-edge of vitality as a species. While a modicum of consciousness may have had survivalist properties during an immemorial chapter of our evolution, further escalations of this faculty appeared to be maladaptive, turning our awareness into a seditious agent working against us. As the Norwegian philosopher concluded, along with others before and after him, we must hamper our consciousness for all we are worth or it will impose upon us a too clear vision of the 'great matter of birth and death', to borrow a phrase from Zen Buddhism. Thus, each of us became a paradox: we could not live with ourselves as we were and we could not live otherwise. We could only keep the horror in its box.

For the rest of the earth's organisms, existence is relatively uncomplicated. Their lives are about three things: survival, reproduction, death – and nothing else. But we know too much to content ourselves with surviving, reproducing, dying – and nothing else. We know we are alive and know we will die. We also know we will suffer at intervals throughout our lives before suffering – slowly or quickly – at the point of death. This is the knowledge we 'enjoy' as the most intelligent organisms to gush from the womb of nature. And as such, we feel shortchanged if there is nothing more for us than to survive, reproduce, and die. We want there to be more to it than that, or to think there is. This is the tragedy: consciousness has forced us into striving to be something other than what we are – hunks of spoiling flesh on hardening bones. For other organisms, life is a well-managed ramble toward their demise. But we are susceptible to startling and dreadful thoughts, and we need some fabulous illusions to take our minds off them. For us, then, life is a con game we must run on ourselves, hoping we do not catch on to any monkey business that would leave us stripped of our defense mechanisms and standing bare-assed before the silent, staring void. To end this self-deception, to free our species from this backbreaking labor of lies, we must cease reproducing. Nothing less will do, per Zapffe, although in 'The Last Messiah' the character after whom the essay is named does all the talking about human extinction. Elsewhere Zapffe speaks for himself on the subject.

More audacious than it is astonishing, Zapffe's thought has a substructure in existential psychology and sociology rather than in metaphysics, analytics, or hard science. It is penetrable and ineluctably dismal, resting on taboo commonplaces and outlawed truisms while eschewing the arcane brain-twisters that for thousands of years have been philosophy's stock-in-trade. *The World as Will and Representation* (two volumes, 1819 and 1844) by the German philosopher Arthur Schopenhauer is perhaps the most handsome metaphysical system ever elaborated, which does not mean that the Will-to-live as the causal agent for everything that moves is not just an overwrought floorshow for brainiacs. But Zapffe's principles are crystalline and therefore could never interest professors or practitioners of philosophy, who prefer to circle around grand exhibitions of theory wherein harsh realities and reeling senselessness are secreted behind elegant explications of what our lives are really about. If we must think, it should be done only in circles, outside of which lies the unthinkable.

MASTERMINDING

Zapffe's two central propositions as adumbrated above are as follows. The first is that consciousness has overreached the point of being a sufferable property of our species, and thus we thwart it in four principal ways.

(1) **ISOLATION.** So that we may get on with living without going into a free fall of trepidation, we isolate the dire facts of being alive. These are stowed away in a remote compartment of our minds. They are the family freaks in the attic whose existence we deny in a conspiracy of silence.

(2) **ANCHORING.** To stabilize our lives in the tempestuous waters of chaos, we conspire to anchor them in metaphysical and institutional 'verities' – God, Morality, Natural Law, Country, Family – that imbue us with a sense of being official, authentic, and safe in our beds.

(3) **DISTRACTION.** To keep our heads unreflective of a world of horrors, we distract them with the worst trash or the best trash. The most operant and elementary method for furthering the conspiracy, distraction is in continuous employ and demands only that everyone keep their eyes on the ball – or television screen or great book.

(4) **SUBLIMATION.** That we might annul a paralyzing stage fright having to do with the nightmare intervals of being alive, we sublimate our fears by making an open display of them. In the Zapffian sense, sublimation is the rarest technique utilized for conspiring against the human race. Putting into play both deviousness and skill, this is the process by which thinkers and artistic types recycle the most demoralizing and unnerving aspects of life as works in which the worst fortunes of humanity are presented in a stylized and removed manner as entertainment. In so many words, these thinkers and artistic types confect products that provide an escape from our suffering by a bogus simulation of it – a tragic drama or philosophical woolgathering, for instance. Zapffe uses 'The Last Messiah' to showcase how a literary-philosophical opus cannot perturb its creator or anyone else with the severity of true-to-life horrors, but only provide a pale representation of these horrors, just as a movie whose centerpiece is the romance of two young people, one of whom dies of leukemia, cannot rend its audience with the throes of the real thing, even if it may produce an award-winning tearjerker, as in the case of the 1971 film adaptation of Erich Segal's 1970 bestselling novel *Love Story*.

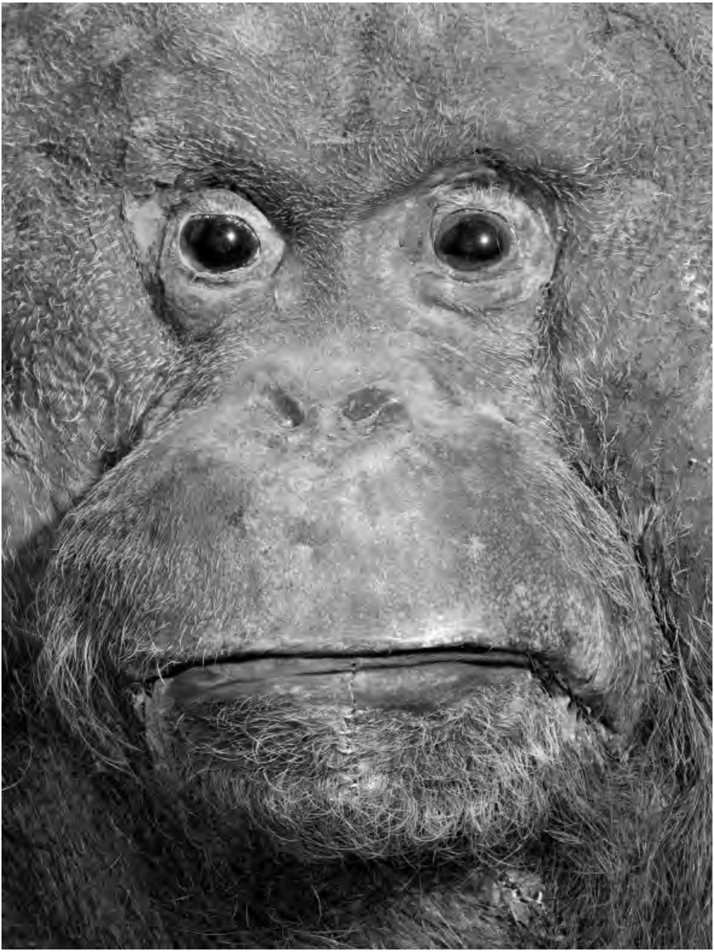
By cleaving to these stratagems, we keep ourselves from scrutinizing too closely the smorgasbord of pain and fear laid out for us by life.

The second of Zapffe's two central propositions – that our species should refrain from reproducing – brings to mind a familiar cast of characters. The Gnostic sect of the Cathari in twelfth-century France were so tenacious in believing the world to be an evil place engendered by an evil deity that its members were offered a dual ultimatum: sexual abstinence or sodomy. (A similar sect in Bulgaria, the Bogomils, became the etymological origin of the term 'buggery' for their practice of this form of erotic release). Around the same period, the Catholic Church mandated abstinence for its clerics, a directive that did not halt them from betimes giving in to sexual quickening. Most sadly, the *raison d'être* for this doctrine was the attainment of grace (and in legend was obligatory for those in search of the Holy Grail) rather than an enlightened governance of reproductive plugs and bungholes. Lusting to empower itself, the Church slacked off from the example of its ascetic founder in order to breed a copious body of followers and rule as much of the earth as it could.

In another orbit from the theologies of either Gnosticism or Catholicism, the nineteenth-century German philosopher Philipp Mainländer (pseudonym of Phillip Batz) advocated chastity as the surest blueprint for salvation. The target point of his redemptive plan was the summoning within ourselves of a 'Will-to-die'. This brainstorm, along with others as gripping, was advanced by Mainländer in a treatise whose title has been translated as *The Philosophy of Redemption.*[3] Unsurprisingly, the work itself has not been translated into English. Perhaps the author might have known greater celebrity if, like the Austrian philosopher

---

[3] *Die Philosophie der Erlösung* (Berlin: Theodor Hofmann, 1879 [second edition])and *Die philosophie der Erlösund: Zwölf philosophische* (Frankfurt am Main: C. Könitzer, 1882-6 [five volumes])



Otto Weininger in his infamous study translated as *Sex and Character* (1903), he had ruminated more *about* the venereal goad rather than *against* it. Mainländer also made the cardinal error of pressing his readers to work for such ends as justice and charity for all. An unbridled visionary, although not of the inspirational sort that receives a charitable hearing from posterity, he shot himself in the foot every chance he got before aiming the gun a little higher and ending his life. This act was consummated the day of the publication of *The Philosophy of Redemption.* To the end, Mainländer avouched his personal sense of well-being and proposed universal suicide for a most esoteric reason (see under the section 'Deicide' below).

A less composed figure than Mainländer was the Italian philosopher Carlo Michelstaedter. In his 1910 doctoral dissertation, published in English as *Persuasion and Rhetoric*[4], the twenty-three-year-old Michelstaedter critiqued, as later would Zapffe, the tactics we use to falsify the realities of human existence in exchange for a speciously comforting view of our lives. Michelstaedter's biographers and critics have speculated that his despair of any person's ability to break through their web of illusions was the cause of his suicide (two bullets from a gun) the day after he finished his dissertation. What seems to have finished Michelstaedter was a stellar fact of human life that he could not accept: no one has control over how they will be in this world, a truth that eradicates all hope if how you want to be is invulnerably self-possessed ('persuaded') and without subjection to a life that would fit you within the limits of its unrealities ('rhetoric', a word oddly used by Michelstaedter).

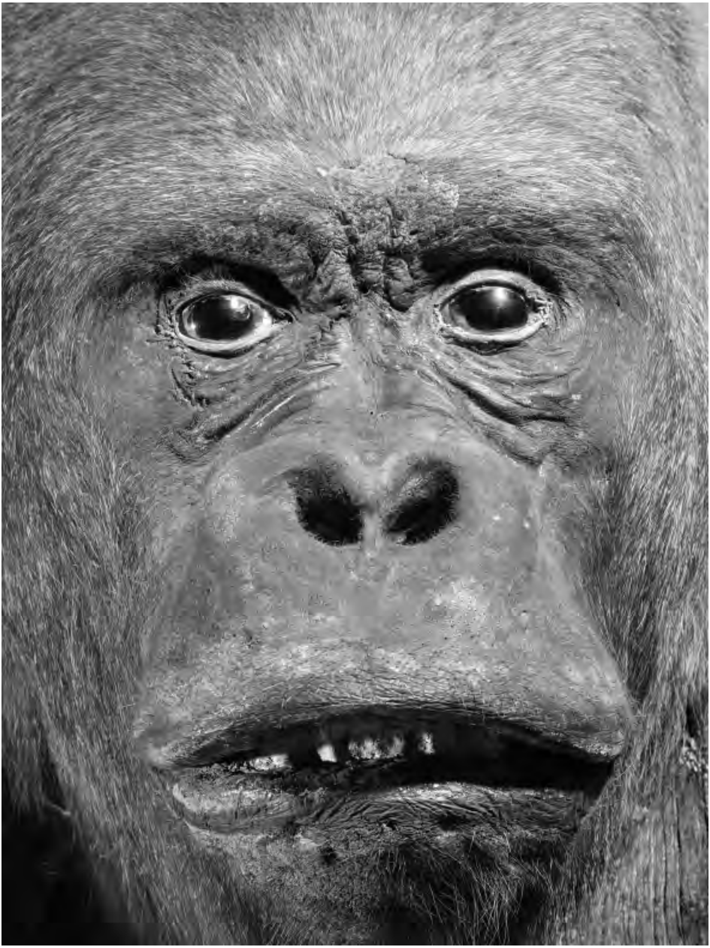
[4] Trans. R. S. Valentino, C. S. Blum, and D. J. Depew. New Haven, Conn./London: Yale University Press, 2004.

But individuals are defined by their limitations; without them, we fall outside the barrier of identifiable units, functionaries in the big show of collective existence. The farther you proceed toward a vision of humankind under the aspect of eternity, the farther you drift from what makes you a person among persons in this world. In the observance of Zapffe, an overactive consciousness endangers the approving way in which we define ourselves and our lives. It does this by threatening our self-limited perception of who we are and by blackmailing us with unsavoury facts about what it means to know we are alive and will die. A person's demarcations as a being, not how far he trespasses those limits, create his identity and preserve his illusion of being someone. Transcending all illusions and their emergent activities would untether us from ourselves and license the freedom to be no one. In that event, we would lose our allegiance to our species, stop reproducing, and quietly bring about our own end. The lesson: 'Let us love our limitations, for without them nobody would be left to be somebody.'

While recognizing the nuisance of conscious existence, not all are as unrelenting in their pessimism as Zapffe. In his 1913 *Tragic Sense of Life in Men and Nations*,[5] the Spanish writer Miguel de Unamuno speaks of consciousness as a disease bred by a conflict between the rational and the irrational. The rational is identified with the conclusions of consciousness, primarily that we will all die. The irrational represents all that is vital in humanity, including a universal desire for immortality. The coexistence of the rational and the irrational turns the human experience into a wrangle of contradictions to which we can submit

---

[5] Republished, trans. A. Kerrigan, Princeton University Press, 1978



with a suicidal resignation or obstinately defy as heroes of futility. Unamuno's penchant is for the heroic course, with the implied precondition that one has the physical and psychological spunk for the fight: 'I think, therefore I know that life is a meaningless bitch and then I will die; but I cannot let that keep me from living in defiance of what I know, which is what everyone does, pessimist or not.' In line with Unamuno, Joshua Foa Dienstag, author of *Pessimism: Philosophy, Ethic, Spirit*,[6] also gives the thumbs-up to the pessimist-as-hero – one who is aware of the dispiriting lowdown on life and yet marches on. Also siding with this never-say-die group is William R. Brashear, whose *The Desolation of Reality*[7] concludes with a format for redemption, however partial and imperfect, by means of what he calls 'tragic humanism', which recognizes human life's 'ostensible insignificance, but also the necessity of proceeding as if this were not so, and of willfully nourishing and sustaining the underlying illusions of value and order'. Not exactly pessimists in the tradition of Schopenhauer or Zapffe, Unamuno, Dienstag, and Brashear are at least vocal about what is at stake for those who know they are alive and will die.

MEANINGFULNESS

Among the unpleasantries of life that lie in wait is the abashment some persons suffer because they feel their lives are destitute of meaning. The sense that one's life has meaning is sometimes declared to be a necessary condition for developing or maintaining a state of good feeling. This is horrendous news considering the mind-boggling number of books and therapies for a market of discontented individuals who are short on a sense of meaning, either in a limited and localized variant ('I received an A on my calculus exam') or one that is macrocosmic in scope ('There is no God but Allah, and Mohammed is his prophet'). Those who are euphoric, or even moderately content, are not parched for meaning. Relatively speaking, feeling good is its own justification. As long as such states last, why louse up a good thing with self-searching interrogations about meaning? But an abnormal degree of elation could also be a sign of psychopathology, as it is for individuals who have been diagnosed with bipolar affective disorder. Such persons should be treated by mental health professionals, although psycho-behavioral therapeutics often puts a patient in the clutches of mind healers who are modern-day incarnations of positive-thinking preachers such as Norman Vincent Peale. No one ever bought a copy of *The Power of Positive Thinking*[8] who was not dissatisfied with his or her life. This dissatisfaction is precisely the quality that the great pessimists – Buddha, Schopenhauer, Freud – saw as definitive of the human packing plant. Millions of copies of Peale's book and its reiterations, including Martin Seligman's *Authentic Happiness: Using the New Positive Psychology to Realize Your Potential for Lasting Fulfillment* ,[9] have been sold. And they were not purchased by readers who were madly content with their place on the ladder of subjective well being, in the vernacular of 'positive psychology'. Neither have they been documented as hoisting themselves toward 'lasting' fulfillment by reading the books of these gurus of happiness.[10]

[10] For a study based on clinical research that documents one's subjective wellbeing

While every other creature in the world is insensate to meaning, those of us on the high ground of evolution are full of this enigmatic hankering, a preoccupation that any comprehensive encyclopedia of philosophy treats under the heading LIFE, THE MEANING OF. We have a need that is not natural, one that can never be satisfied no matter how many big lies we swallow. Our unparalleled craving may be appeased – like the yen of a dope fiend – but we are deceived if we think it is ever gone for good. Years may pass during which we are unmolested by LIFE, THE MEANING OF. Some days we wake up and just say, 'It's good to be alive'. If everyone were in such elevated spirits all the time, the topic of LIFE, THE MEANING OF would never rise up in our heads or our conversations. But this ungrounded jubilation soon runs out of steam. Our consciousness, having snoozed awhile in the garden of incuriosity, is pricked by some thorn or other, perhaps DEATH, THE MEANING OF. Then the hunger returns for LIFE, THE MEANING OF, the emptiness must be filled again, the pursuit is resumed. And we will keep chasing after the impossible until we are no more. This is the tragedy that we do our best to cover up in order to brave an existence that holds terrors for us at every turn, with little but blind faith and habit to keep us on the move.

HUMANNESS

As heretofore posited, consciousness may have facilitated our species' survival in the hard times of prehistory, but as it became evermore acute it evolved the potential to ruin everything if not securely muzzled. This is the problem: we

---

as a genetically determined lottery and not something that a self-help book can instruct an individual to achieve, see 'Happiness Is a Stochastic Phenomenon' by David Lykken and Auke Tellegen, *University of Minnesota Psychological Science*, 1996. Believe it or not.

must either outsmart consciousness or be thrown into its vortex of doleful factuality and suffer, as Zapffe dubbed it, a 'dread of being' – not only of our own being but of being itself. On the strength of this premise, Zapffe inferred that the sensible thing to do would be to call off all procreative activities. Not only would it be the sensible thing to do, but it might be the most telling indication, even the *only* indication, of what it means to be human. This could settle some old questions. Is the condition of being human what we think it is? And what do we think it is to be human? Nowhere in philosophy or the arts are there answers on which we can all agree. Science has us down as a species of organic life. But whatever it means to be human, we can at least say that we have consciousness – an attribute that has made us the royalty of creation, yet one that we cannot let get out of hand if we are to survive. Question: why would we want to survive as a species caught in this double bind? Answer: because we do not know what it is to be human.

To repeat what cannot be repeated enough: we can tolerate existence only if we believe – in accord with a complex of illusions, a legerdemain of deception – that we are not what we are: unreality on legs. As creatures with consciousness, we must suppress that divulgement lest it break us with a sense of being things without significance or foundation, anatomies shackled to a landscape of pointless horrors. In plain language, we cannot live with ourselves except as impostors, paradoxical beings who must lie to ourselves about ourselves, as well as about our no-win situation in this world. Thus, we are zealots of Zapffe's four consciousness-smothering strategies: isolation ('Being alive is all right'), anchoring ('One Nation under God with Families, Morality, and Natural Laws for all'), distraction

(‘Better to kill time than kill oneself’), and sublimation (‘I am writing a book entitled *The Conspiracy Against the Human Race*’). These practices make us what we are – beings with a nimble intellect who can deceive themselves ‘for their own good’. Isolation, anchoring, distraction, and sublimation are the wiles we use to keep our heads from dispelling every illusion that keeps us up and running. (‘We think, therefore we know we are alive and will one day die; so we had better stop thinking, except in circles.’) Without this cognitive double-dealing, our world would be seen for what it is – something that is not very good to see, something that everyone glimpses from time to time and then looks away because they do not want to see too much of it. Maybe if we could resolutely gaze wide-eyed at our lives we would know what it is to be human. But that would stop the puppet show that we like to think will run forever.

In ‘The Last Messiah’, Zapffe wrote: ‘The whole of living that we see before our eyes today is from inmost to outmost enmeshed in repressional mechanisms, social and individual; they can be traced right into the tritest formulas of everyday life.’[11] The four formulas that Zapffe picked out as individual and social mechanisms of repression are probably the most trite he could have chosen, which may have been deliberate on his part because they are so familiar to us and so visible in human affairs. No one hesitates to admit them. Not overweight persons or tobacco users, who will promptly admit to playing dumb when they are scarfing down a cupcake or smoking a cigarette. Not soldiers fighting a war, who will proudly admit they are risking their lives and limbs for a good greater than themselves – their families, their country, their god. Not anyone who is going to die soon, who will not voluntarily admit to playing the same old games for as long as possible rather than be consumed by thoughts of mortality and the agony that may precede it. Not artists, who with a shrug will admit to keeping their aesthetic distance for fear of being hamstrung by the realities they instantiate (musicians practice distraction rather than artistic sublimation). Such repressional mechanisms have been well analyzed by professional thinkers, particularly in relation to the fear of death. (For an enumeration of these and other mechanisms for grappling with thanatophobia, see *Choices for Living: Coping with the Fear of Dying*[12] by Thomas S. Langer). For almost all philosophers who write on the subject, death is studied in the abstract, while the more messy truths attending it are either bracketed or cold-shouldered. Death, of course, is only a sub-category of suffering, which, if it is even recognized by philosophers, is not something they care to brood upon. Suffering cannot be studied in the abstract. Philosophically, there is not much that can be done with it, and those few who try will be arraigned for talking nonsense. Almost all philosophers balk at saying anything about SUFFERING, THE MEANING OF. But none of them hesitate to admit that they, in league with everyone else, employ repressional mechanisms in their lives. And what use are repressional mechanisms if not to avoid discussions about suffering?

SUFFERING

In *The Open Society and Its Enemies*,[13] Karl Popper expounded a new slant on human suffering. Briefly, he revamped the Utilitarianism of the nineteenth-century British philosopher John Stuart Mill, who wrote, ‘Actions are right in proportion as they tend to promote happiness, wrong as they tend to promote the reverse of happiness’. Popper remolded this summation of a positive Utilitarianism into a *negative* Utilitarianism whose position he handily stated as follows: ‘It adds to clarity in the fields of ethics, if we formulate our demands negatively, i.e. if we demand the elimination of suffering rather than the promotion of happiness.’ Taken to its logical and most humanitarian conclusion, Popper’s demand can have as its only end the elimination of those who now suffer and those who will suffer if they are born. What else could the ‘elimination of suffering’ mean if not its total abolition, and ours? Naturally, Popper held his horses well before suggesting that to eliminate suffering would demand that we as a species be eliminated. But he should still be applauded for promoting the basics of a school of thought that would prefer to eliminate suffering – or at least tone it down – than to promote happiness in human life.

Other philosophies of a similar type as Negative Utilitarianism are Abolitionism and Algonomy. The people behind these incipient movements are fiery battlers against a world that is effectively indifferent to human suffering, which they have situated as the only problem with being alive. Abolitionism has gone so far as to preach that not only should human beings be emancipated from suffering, they should also know what it is like to feel unbroken bliss throughout their lives and no mental or physical inconvenience upon their deaths – a Utilitarianism beyond positivity or negativity. While no safe and efficient means yet exists to reach this peak existence, the parent figure of Abolitionism, the British philosopher David Pearce, has encyclopedically catalogued the ameliorations for suffering that now exist and has brilliantly outlined what steps we should presently be taking toward a life of engineered happiness. Nevertheless, an Abolitionist life would still not be perfect, since painful fatalities caused by accidents and natural disasters can never be gotten around. And such a life would be as useless as any other. That having been said, the existence that Pearce wants for the human race would at least not be malignant through and through, since it would turn the suffering with which we are drenched into a shower of (mostly) pleasurable sensations.

---

[13] London: Routledge, 1945.

In 'The Last Messiah', Zapffe is not sanguine about eliminating suffering, nor is he so unworldly as to beseech a communal solution for its elimination by snuffing out the human race, as did the Cathari and the Bogomils. (He does critique the barbarism of social or religious proscriptions of suicide, but he is not a standard-bearer for this form of personal salvation). Zapffe's thought is foremost an addendum to that of various sects and individuals who have found human existence to be so unquestionably awful that extinction is preferable to survival. It also has the value of advancing a new answer to the old question 'Why should generations unborn be spared entry into the human thresher?' But what might be called 'Zapffe's Paradox', in the tradition of possessively named formulations that saturate primers of philosophy, is as useless as the propositions of any other thinker who is pro-life or anti-life or is only juggling concepts to clinch what is reality and can we ever

get there. Having said as much, we can continue as if it had not been said. The value of a philosopher's thought is not in its answers – no philosopher has any that are more helpful than saying nothing at all – but in how well they speak to the prejudgments of their consumers. Such is the importance – and the nullity – of rhetoric. Ask any hard-line pessimist, but do not expect him to expect you to take his words seriously.

The greatest strike against philosophical pessimism is that its only theme is human suffering. This is the last item on the list of our species' preoccupations and detracts from everything of any importance to us, such as the Good, the Beautiful, and tomorrow's weather. Cures may be discovered for certain diseases and sociopolitical barbarities may be amended, but these are only stopgaps. Human suffering is insoluble as long as human beings exist. The one truly effective solution for suffering is that spoken of in Zapffe's 'Last Messiah'. It may not be a realistic solution for a stopgap world, but it is one that would forever put an end to suffering, should we ever care to do so. The pessimist's credo, or one of them, is that nonexistence never hurt anyone and that conscious existence hurts everyone. (Uneasy indeed are the heads that wear the crown of creation). Without consciousness we would still know pain; suffering, however, would not disturb us.

The twentieth-century Austrian philosopher Ludwig Wittgenstein once said or wrote, 'I don't know why we are here, but I'm pretty sure it is not in order to enjoy ourselves'. But Wittgenstein's uncertain determination does not go to the heart of human existence. Hedonism is irrelevant as a justification for our lives. No price is too high for our creaturely reward of just being here and knowing that others will be here after us. This is our 'pleasure', and no amount of suffering will lead our species to question it. While this pleasure began as a relief from the anxieties of genealogical slippage, it now stems in the main from psychological satisfactions. The modern family unit is an indulgence, not a necessity. It is a satisfaction of the ego or an appurtenance of one's public image. Children are not economic insurance for their families but consumer goods, personal accessories, trinkets or tie-clips. No longer their parents' *employees*, as in earlier days, they strike out on their own and go into business for themselves when sufficient capital has been accumulated or may be borrowed – life on the installment plan.

But if the price of suffering has fallen – not that it was ever unaffordable – we still must deal with a progressively insidious consciousness, that invader of our homes and heads. Zapffe's achievement as a pessimist treads beyond plaints of how rich with suffering life can be. We – as genetic donors consorting two by two for the protraction of our species – have no problem with suffering. The problem for us – as billions of lone individuals who mingle but can never merge with one another – is the pyrotechnics of cogitation we must perform to stave off our consciousness of pain, of death, of life as a danse macabre into which we are always pulling new partners and lying to them as we lie to ourselves.

Our success as a survival-happy species is calculated in the number of years we have extended our lives, with the reduction of suffering being only incidental to this aim. The lifespan of non-domesticated mammals has never changed, while ours has grown by leaps and bounds. What a coup for us. Unaware of the length of their stay on earth, other warm-blooded life forms are sluggards by comparison. Without consciousness of death, we would not frantically rouse ourselves to lengthen our mortal tenure. And how we have cashed in on our efforts: no need to cram our lives into three decades now that we can cram them into seven, eight, nine, or more. Time will run out for us as it does for all creatures, true, but at least we can dream of a day when we might *choose* our own deadline. Then everyone could die of the same thing: satiation with a durability that is MALIGNANTLY USELESS. Without a terminus for the journey of our lives, their uselessness would become excruciatingly overt. Knowing ourselves to be on a collision course with the Black Wall of Death may be a horror, but it is the only thing that makes it possible to value that which comes before, if we are not too cast down by thoughts of our mortality to do so. While this quid pro quo may be a bad value, without it there is no value. Only a terminal point, only *endness*, can make the present seem precious, although the here-and-now is almost invariably taken for granted so that we can squander what little time we have by looking cockeyed to the future. It is in the future that we expect to inherit a greater value than that which trickles backwards into our lives from their certain end. But as everyone knows, even though we disregard this knowledge, the future is only the present in disguise, and as soon as it arrives we begin hunting for *another* future. Not until the future is behind us can there be any peace on this earth or in our heads. If only we could end our arduous voyage to a fool's future, Zapffe's prospectus for our self-extermination would be a walk in the park. At all levels, the systems of life – from sociopolitical systems to solar systems – are repugnant and should be negated as MALIGNANTLY USELESS.

'Worthless' rather than 'useless' is the more familiar epithet in this context. The motive for using 'useless' in place of 'worthless' in this histrionically capitalized phrase is that 'worthless' is tied to the concepts of desirability and value, and by their depreciation introduces them into the mix. 'Useless', on the other hand, is not so inviting of these concepts. 'Worthless' can serviceably be connected to the language of pessimism and does what damage it can. But the devil of it is that 'worthless' really does not go far enough when speaking pessimistically about the character of existence. Too many times the question 'Is life worth living?' has been asked. This usage of 'worth' excites impressions of a fair lot of experiences that are arguably desirable and valuable within limits and that follow upon one another in such a way as to suggest that life is not worthless overall, or not so worthless that a case could not be made for its worth. With 'useless', the spirits of desirability and value do not as readily rear their heads, and existence as dizzying pointlessness state of affairs may be more intemperately asserted. Naturally, the uselessness of all that is or could be may be repudiated as well or badly the worthlessness of all that is or could be. For this reason, the adverb 'malignantly' has been annexed to 'useless' to give it a little more semantic stretch, if not enough to deter any rebuttals from the opposition. But to express with any adequacy a sense of the sucking uselessness of everything, a nonlinguistic modality would be needed, some effusion out of a dream that coalesced every nuance of the useless and wordlessly transmitted to us the inanity of any possible thing, conception, or condition. Indigent of such means of communication, the uselessness of all that exists or possibly could exist must be spoken with a poor potency.

Of course, everyone believes there are things, conceptions, and conditions that are not useless. We all live within relative frameworks where something may not be useless – in a practical way – with respect to something else. A potato masher is not useless if one wants to mash potatoes. For some people, a system of being that includes a god may not seem useless, possibly because it involves concepts such as eternity and infinity. Yet even something that involves concepts such as eternity and infinity is not saved from being useless except within a relative framework of what is not eternal or infinite. It would then not be useless only in the same relative capacity as a potato masher. As long as there are entities that are relative to one another, they will be potato-masher entities. And if there were a god that had no relation to anything that was not that god – that was not relative to anything because nothing else existed – then such a thing would be the paradigm of uselessness, being that there would be nothing for which it could not be useless. Should that god drum up a universe in which there were things for which it would not be useless, it could only be a potato-masher god. Far more likely in the minds of many people is that the universe was drummed up without a god, thereby making the uselessness of that universe, except in the potato-masher relations of its part, unbelievably evident. Some people do not get up in arms about the relativity of everything; others do. The latter want to worship gods that are not just potato-masher gods or to think in terms of absolutes that are really absolute and not just absolute potato-mashers. They cannot accept an existence in which everything is MALIGNANTLY USELESS except as some species of potato masher. They particularly do not like to think that they themselves are potato-masher things living potato-masher lives in a potato-masher world.

Christians, Jews, and Muslims have a real problem with a potato-masher world. Buddhists have no problem with it because for them the way to salvation is to realize the truth of ‘dependent origination’, which means that everything is related to everything else in a great network of potato mashers that are always interacting with one another. So the only problem Buddhists have is not being able to realize that everything is a great network of potato mashers. They think that if they could get over this hump, then they would be forever liberated from suffering. In the Buddhist faith, everyone suffers who cannot see that the world is a MALIGNANTLY USELESS potato-mashing network. Contrary to Christians, Jews, and Muslims, Buddhists do not have the handicap of believing in a god or even in their own reality, although they do have other handicaps.

DISCONTENT

Being royally conscious of the solemn precincts in which we exist, of the savage wasteland and sordid burlesque that lies beneath life’s piddling nonsense, would turn us to dust. Saddled with self-knowledge, we thrive only insofar as we vigilantly obfuscate our heads with every baseless belief or frivolous recreation at our disposal. But as much as our heads are inclined to clog themselves with such trash, a full-scale blockage is impossible. This impossibility makes us heirs to a legacy of discontent. In his study *Suicide* (1897), the French sociologist Emile Durkheim contended that ‘one does not advance when one proceeds toward no goal, or – which is the same thing – when the goal is infinity. To pursue a goal which is by definition unattainable is to condemn oneself to a state of perpetual unhappiness’. Who can gainsay that the goal of our race has no visible horizon and therefore, in Durkheim's view, we are doomed, as the French thinker rather euphemistically put it, to 'a state of perpetual unhappiness'? Along similar lines, psychoanalyst Adam Phillips writes in his *Darwin's Worms: On Life Stories and Death Stories*:[14] 'Tyrannical fantasies of our own perfectibility lurk in even our simplest ideals, Darwin and Freud intimate, so that any ideal can become another excuse for punishment. Lives dominated by impossible ideals, complete honesty, absolute knowledge, perfect happiness, eternal love are experienced as continuous failures.' (Phillips' twist of mind may be seen as self-serving due to his belief in psychoanalysis, which by its nature is not designed to make people happy on a tight schedule, or to make them happy at all). To counter these glum assessments of things, the world's religions all offer goals that they say are very much attainable, if only in the afterlife or the next life.

In *The Myth of Sisyphus* (1942), existentialist superstar Albert Camus represents the unattainable goal of the title figure as an apologetic for going on with life rather than ending it. As Camus insisted in his discussion of this gruesome parable, 'We must imagine Sisyphus as happy.' The credo of the Church Father Tertullian, 'I believe because it is absurd', might as rightly be attributed to Camus. Caught between the fabrications of the Carthaginian and the rationalizations of the Frenchman, Zapffe's proposal that we put out the light of the human race extends to us a solution to our troubles that is infinitely more satisfying than that of either Tertullian or his modern avatar Camus, who considered suicide as a philosophical issue for the individual yet, by some oversight, did not entertain the advantages of an all-out attrition of the species. Aside from a repertoire of tricks we can do that other animals cannot, the truest indicator of a human being is unhappiness. The main fount of that unhappiness, as Zapffe and others have written, is our consciousness. And the more dilated consciousness becomes, the more unhappy the human. In the end, Camus' injunction that we *must* imagine Sisyphus as happy is as unavailing as it is feculent.

---

[14] London: Faber, 1999.

On the subject of whether or not life is worth the trouble, the answer must always be unambivalent . . . and positive. To teeter the least bit into the negative is tantamount to moral suicide. If you value your values, no doubts about this matter can be raised, unless they occur as a lead-up to some determinate affirmation. In the products of high or low culture, philosophical disquisitions, and arid chitchat, the anthem of life *must* forever roar above the squeaks of dissent and *must* be delivered to us without abatement or appreciable contradiction. We were all born into a rollicking game that has been too long in progress to allow a substantive change in the rules. Should the incessant fanfare that meets your ears day in and day out sound out of tune and horribly inappropriate, you will be branded *persona non grata* and welcome wagons will not stop at your door. So if you know what is best for you and want a good seat from which to watch human existence as it goes by, you must *not* recognize Zapffe's proposal for the salvation-by-extinction of the human race as a solution to the absurdity of life.

Those who treasure philosophical and literary works of a pessimistic, nihilistic, or defeatist nature as indispensable to their existence are hopelessly frustrated with living in a world on autopilot when they would like to switch it over to manual consciousness and nosedive humanity into a crash without survivors. On the flip side, most ordinary

people can live with discontent because it is concomitant with their expectation that humanity will forever 'survive' (Middle English by way of Middle French from the Latin *supervivere* – to outlive or live beyond). Bulletin: we, as a subcategory of the *mélange* of earth's organisms, may outlive other species, but we will not live beyond our own time of extinction, as over ninety-nine percent of preceding life forms on this planet have not lived beyond theirs. We can pretend this will not happen, fantasizing super-scientific eternities, but in good time we will be taken out of the scene. This turn of events will be the defeat of Project Immortality, which has been in the works for millennia.

MISTAKE

Consciousness is an existential liability, as every pessimist agrees. It is also a mistake that has taken humankind down a black hole of logic: to make it through this life, we must pretend that we are what we are not, according to Zapffe's Paradox. To correct this mistake, we should desist from procreating. What could be more judicious or more urgent? At the very least, we might give some regard to this theory of the mistake as a 'thought-experiment'. All civilizations become defunct. All species die out. All the suns of all the galaxies will blow up. There may even be an expiration date on the universe itself. Human beings would certainly not be the first phenomenon to go belly up. But we could be the first to spot our design-flaw, that absent-minded flub of nature called consciousness, and do something about it. And if we are mistaken about consciousness being a mistake, our self-removal from this planet would still be a magnificent move on our part, the most laudable masterstroke of our existence, and the only one. No evil would attend our departure from existence, and the many evils we have known would go extinct along with us.

Taking our leave from life might seem a thoroughly negative course of action, but it is not as simple as that. Every negation is adulterated or secretly initiated by an affirmative spirit, mass suicide included. An unequivocal ‘no’ cannot be uttered or acted upon. Lucifer’s last words in heaven may have been ‘Non serviam’, but none has served the Almighty so well, since His sideshow in the clouds would never draw any customers if it were not for the main attraction of the devil’s hell on earth. Only catatonics and coma patients have what it takes to sit out the horseplay of creation. Without a ‘yes’ in our hearts, nothing would be done. And to be done with our existence *en masse* would be the most ambitious affirmation of all.

With regard to consciousness, ‘fluke’ or ‘mutation’, rather than ‘mistake’, would be more accurate terms in the present discussion, since it is not in the nature of Nature to make mistakes – it just makes what it makes. ‘Mistake’ has been used for its pejorative connotation in ‘The Last Messiah’. Of course, phenomena other than consciousness have been thought to be a mistake, beginning with life itself. For example, in a novel titled *At the Mountains of Madness* (1936), the American writer H. P. Lovecraft has one of his characters mention a ‘primal myth’ about ‘Great Old Ones who filtered down from the stars and concocted earth life as a joke or mistake’. Schopenhauer, once he has drafted his theory that everything in the universe is energized by a Will-to-live, shifts to a commonsense pessimism to visualize a species inattentive to the possibility that its life is a concatenation of snafus.

> Many millions, united into nations, strive for the common good, each individual for his own sake; but many thousands fall sacrifice to it. Now senseless delusion, now intriguing politics, incite them to wars with one another; then the sweat and blood of the multitude must flow, to carry through the ideas of individuals, or to atone for their shortcomings. In peace, industry and trade are active, inventions work miracles, seas are navigated, delicacies are collected from all the ends of the earth; the waves engulf thousands. All push and drive, some plotting and planning, others acting; the tumult is indescribable. But what is the ultimate aim of it all? To sustain ephemeral and harassed individuals through a short span of time, in the most fortunate cases with endurable want and comparative painlessness (though boredom is at once on the lookout for this), and then the propagation of this race and of its activities. With this evident want of proportion between the effort and the reward, the will-to-live, taken objectively, appears to us from this point of view as a folly, or taken subjectively, as a delusion. Seized by this, every living thing works with the utmost exertion of its strength for something that has no value. But on closer consideration, we shall find here also that it is rather a blind urge, an impulse wholly without ground and motive.[15]

Schopenhauer is here straightforward in limning his awareness that, for human beings, being alive is all 'folly' and 'delusion'. He also noted elsewhere in his work that consciousness is 'an accident of life'.

Schopenhauer's is a great pessimism, not least because it revealed a pattern underlying the pessimistic imagination. As indicated, Schopenhauer's insights are yoked to a philosophical superstructure centered on the Will, or the

---

[15] *The World as Will and Representation,* trans. E. J. F. Payne (NY: Dover, 1969).

Will-to-live, a blind, deaf, and dumb force that surfaced for reasons unknown, assembled a universe, and, once human bodies had shot up within it, mobilized them to their detriment. While Schopenhauer's metaphysics is impossible to swallow and could never persuade anyone of its validity, no intelligent person can fail to see that every living thing behaves *exactly* in conformance with his thought in its liberal articulation: wound up like toys by some force – call it Will, *élan vital*, *anima mundi*, or whatever – organisms go on running until they run down. In pessimistic philosophies, only the force is real, not the things that are activated by it. They are only automata, puppets, and, if they have consciousness mistakenly, believe that they are self-winding selves and not self-conscious nothings suffering from Zapffe's Paradox. Here, then, is the pattern Schopenhauer made discernable in pessimism: behind and beyond the scene of life, there are machinations that are not amenable to resistance or control. For Zapffe, consciousness is a mistake, but it is also a mystery whose workings elude us while we are tugged along by the invisible hand of nature to survive and reproduce. For Unamuno, we are prodded by an irrational and irresistible vitalism to letch after immortality. For Michelstaedter, individuals are fitted into a straightjacket by faceless doctors who control their patients' minds with unrealities. For Mainländer, a Will-to-die, not a Will-to-live, plays the occult master pulling our strings.

Of a kind with these scheming powers that the pessimist places in the background of life are those enormities that skulk within the narratives of the great supernatural horror writers. In conceiving Azathoth, that 'nuclear chaos' which 'bubbles at the center of all infinity', Lovecraft might well have been thinking of Schopenhauer's Will. In 'The

Willows', the twentieth-century British writer Algernon Blackwood suggests the existence of a minatory force as unseen and pitiless as Zapffe's Nature. Such supernatural writers are great because they do not follow the rules of popular horror literature: there are no 'good versus evil' scenarios in their stories and no one need survive to make for a good ending. Human beings are set up to be destroyed, as they are in reality, and their destruction occurs not in an everyday world bustling with life and pleasure but in hermetic haunts bustling with death and suffering.

ECOCIDE

Despite Zapffe's work as a philosopher, although not in an occupational capacity (he earned his living by writing poems, plays, stories, and humorous pieces), he is nonetheless better known as an early ecologist who popularized the term 'biosophy' to name a discipline that would broaden the compass of philosophy to include the interests of other living things besides human beings. Thereupon, he serves as an inspiration to the environmentalist agenda, the politics of the health of the earth. Here, too, we catch ourselves – and Zapffe himself, as he affirmed – in the act of conspiring to build barricades against the odious facts of life by isolation, anchoring, distraction, and sublimation as we engage in an activity (in this case the cause of environmentalism) that bypasses the perennial issue. Vandalism of the environment is but a sidebar to humanity's refusal to look its fate in the face. We live in a habitat of unrealities – not of earth, air, water, and wildlife – and cuddly illusion trumps grim logic every time. Some of the more militant environmentalists, however, have concurred with Zapffe that we should retire from existence, although their advocacy of abstinence and universal suicide to save the earth from being pillaged by human beings is not exactly what the philosopher had in mind. While a worldwide suicide pact is highly appealing, what romantic fabrications would cause one to take part in it just to conserve this planet? The earth is not our home. We came from nothing, and to that condition our nostalgia should turn. Why would anyone care about this dim bulb in the blackness of space? The earth produced us, or at least subsidized our evolution. Is it really entitled to receive a pardon, never mind the sacrifice of human lives, for this original sin – a capital crime in reverse (just as reproduction makes one an accessory before the fact to an individual's death)? Someone once said that nature abhors a vacuum. This is precisely why nature should be abhorred. Instead, the nonhuman environment is simultaneously extolled and ravaged by a company of poor players who can no longer act naturally. It is one thing for animals to feed and fight and breed in an unthinking continuance of their existence. It is quite another for humans to do so, since it is possible for us to ask the wholly legitimate question: 'Is it really all right for us to be alive and know that we will die?'

It might be theorized that the human species evolved to serve as nature's roundabout way of cutting into its veins and bleeding out. A strange idea, no protesting that, but not the strangest we have ever heard or lived by. We could at least take up the theory and see where it leads. If it is false, then where is the harm? But until it is proven so, we must let ourselves be drawn along by nature's plan, as we always have, if only by twiddling our thumbs and letting its suicidal course continue without interference. From a human vantage, would this not be a just self-punishment on nature's part for fashioning a world in which pain is essential, a world that could not exist without pain, a world where pain is the guiding principle of all organisms, which are inexorably pushed by pain throughout their lives to do that which will improve their chances to create more of themselves? Left unchecked, this process will last as long as a single cell remains quivering in this cesspool of the solar system, this toilet of the galaxy. So why not lend a hand in assisting nature's suicide, in case it has second thoughts? For want of a deity, let the earth take the blame for our troubles. What else is it good for? Let it save itself if it can – the condemned are known for the acrobatics they will execute to wriggle out of their sentences – but if it cannot destroy what it has made, then may it perish along with every other living thing it has brought forth in pain. While pain is not a problem for species, even a hyper-conscious hive of creatures such as human beings for whom pain has been upgraded to suffering, it is not a phenomenon whose praises are often sung.

DEICIDE

The idea of a self-destructing nature parallels Mainländer's fantasy in which the Will-to-die that should inhere in humanity is only a reflection of the death wish of a God who, in the beginning, masterminded His own quietus from an existence He did not want to spin out any longer than it had already been spun. God's plan to suicide himself could not work, though, while he existed as a unified entity outside of space-time and matter. Seeking to nullify His oneness so that He could be delivered into nothingness, he disintegrated Himself – big bang-like – into the time-bound fragments of the universe, which included organic life forms. In Mainländer's philosophy, 'God knew that he could change from a state of super-reality into non-being only through the development of a real world of multiformity.' Through this method, He excluded Himself from existence. 'God is dead', wrote Mainländer, 'and His death was the life of the world'. Once the great individuation had been accomplished, the momentum of its creator's self-annihilation would continue until nothing remained standing. And those who committed suicide, as did Mainländer, would only be following God's example and moving toward the end of the Creation. Furthermore, the Will-to-live that Schopenhauer argued activates the world was revised by his disciple Mainländer as evidence not of a movement of a tortured life within beings, but as a deceptive cover for an underlying will in all things to burn themselves out as hastily as possible in the fires of becoming ... or begoing, as it were. In this light, human progress is shown to be an ironic symptom that our downfall into extinction has been progressing nicely, because the more things changed, the more they progressed toward a reliable end.

While the wisdom of religions such as Christianity and Buddhism is all for leaving this world behind, their leave-taking is for destinations unknown and impossible to conceive. For Mainländer, these destinations do not exist. His forecast is that one day our will to survive in this life or any other will be universally extinguished by a conscious will to die and stay dead, after the example of God. From the standpoint of Mainländer's philosophy, Zapffe's Last Messiah would not be an unwelcome sage but a crowning force that has been in the works since God took his own life. Rather than resist our end, as Mainländer concludes, we will come to see that the knowledge that life is worthless is the flower of all human wisdom. Elsewhere the philosopher states, Life is hell, and the sweet still night of absolute death is the annihilation of hell. Mainländer's cosmic scenario, inhospitable as it is to all other ideations that include a god-figure, should give pause to those absorbed with supernatural schemes that are no less bizarre (for example, the much-studied soteriology of the Gnostics). Consider this: if God exists, or once existed, what would He not be capable of doing? Why should God not want to be done with Himself as a reaction to His suffering the sickness and pain now reflected in His creation? Why should He not have kicked off a universe that is one great puppet show destined by Him to be crunched or scattered until an absolute nothingness has been established? Why should He fail to see the benefits of nonexistence, as many of us lesser beings have? Alone and immortal, nothing needed Him. In the same way, nothing in this world needs us, which could be why we created a god who pays attention to everything we do, since no other organism cares about us or could be diminished by our extinction. (Quite the opposite). Mainländer's first philosophy, and last, is in fact odd, but no more so than those of any religious or secular ethos that presupposes the worth of human life. Both are objectively insupportable and come out of nowhere: they are only propensities in search of validation.[16]

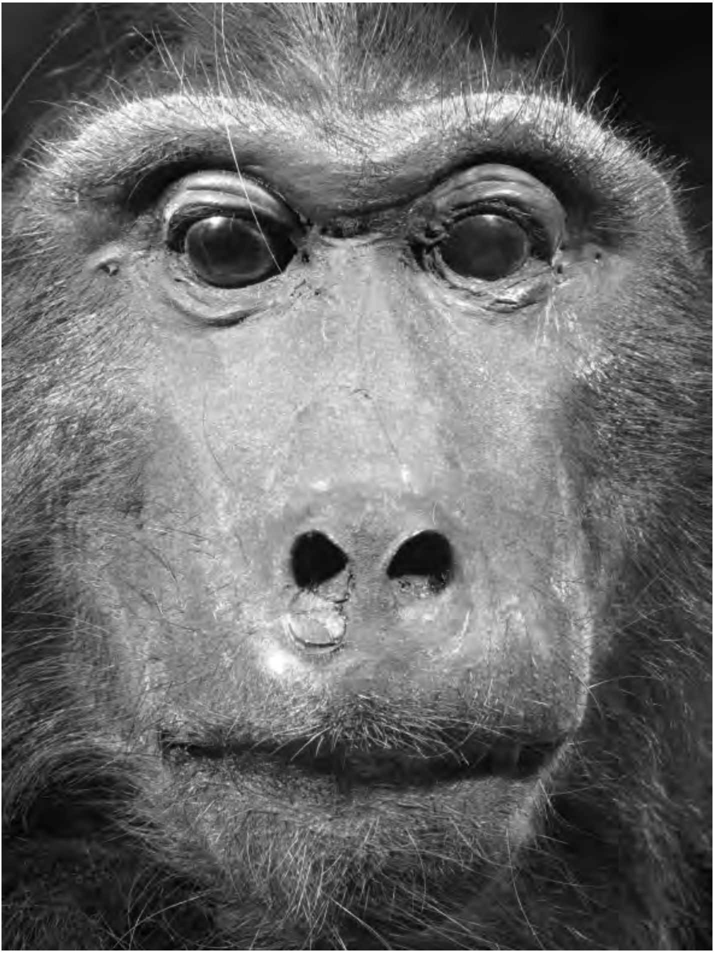
For a rebuttal of Mainländer's thought, see H. P. Blavatsky's 'The Origin of Evil' in the October 1897 issue of the journal *Lucifer*.



PESSIMISM

It would be a sign of callowness to bemoan the fact that pessimistic writers do not rate and may be denounced in both good conscience and good company. This judgment makes every kind of sense in a world of card-carrying or crypto-optimists. Once you understand that, you can spare yourself from suffering excessively at the hands of 'normal people', a pestilent confederation of upstanding creatures who in concert keep the conspiracy going by rehashing their patented banalities and watchwords. This is not to say that such people do not have their struggles and responsibilities, their pains and sufferings, and their deaths by accident, murder, or disease, which only makes all the more pestilent their normal thinking that being alive is all right and that happiness should attend upon the arrival of life's newcomers, who, it is always assumed, will be normal.

Phobic to any somber cast of thought, humankind as nonetheless imbibed ever-increasing disillusionments throughout its history. The biblical Genesis, along with all other fables of origination, has been reduced to a mythic analogue of the big bang theory and the primordial soup. Pantheon after pantheon has been belittled into 'things people used to believe'. And petitions for divine intervention are murmured only inside the tents of religious fanatics and faith-healers. In the past century or so, disillusionments of this kind have become the province of specialists in the various sciences, so they are not well understood by, if known to, those who go to church on Sunday and read the astrology column in the newspaper the rest of the week. Generalists of disillusionment broadcast on a wider frequency. Yet their message, a repetitive dirge that has been rehearsed for thousands of years, is received only by epicures of pessimism, cognitive mavericks who have impetuously circled the field in a race to the finish line.

Contemporaneous with every generation, disillusionment must proceed furtively. Anyone caught trying to accelerate its progression will be reprimanded and told to sit in the corner. While the Church has lost its clout to kill or torture dissenters such as Zapffe, Schopenhauer, and Lovecraft, they are still under watch by guard dogs both sacred and secular. A sign of progress, some would say. But sufferance of such minds should not lead us into premature self-congratulation. The pace at which our kind plods toward disillusionment is geologically slow, and humanity can be cocksure of kicking the bucket by natural causes or an 'act of God' before it travels very far toward that radiant day when with one voice it might cry out, 'Enough of this error of conscious life. It shall be passed down no longer to those innocents unborn'.

Spectral Dilemma[1]

Quentin Meillassoux

Mourning to come, god to come.

> […] every man has two things belonging to him, namely, a life and a phantom.[2]

1. THE SPECTRAL DILEMMA

What is a spectre? A dead person who has not been properly mourned, who haunts us, bothers us, refusing to pass over to the 'other side', where the dearly-departed can accompany us at a distance sufficient for us to live our own lives without forgetting them, but also without dying their death – without being the prisoner of the repetition of their final moments. Then what is a spectre become the essence of the spectre, the spectre *par excellence*? A dead person whose death is such that we cannot mourn them.

---

[1] Originally published as 'Dilemme Spectrale', in *Critique* 704-705, Jan/Feb 2006.

[2] E. Tylor, *Religion in Primitive Culture* (New York: Harper and Row, 1950), 12.

That is to say: a dead person for whom the work of mourning, the passage of time, proves inadequate for a tranquil bond between them and the living to be envisaged. A dead person the horror of whose death lays heavy not only upon their nearest and dearest, but upon all those who cross the path of their history.

Essential spectres are those of terrible deaths: premature deaths, odious deaths, the death of a child, the death of parents knowing their children are destined to the same end – and yet others. Natural or violent deaths, deaths which cannot be come to terms with either by those whom they befall, or by those who survive them. Essential spectres are the dead who will always refuse to 'pass over', who obstinately cast off their shroud to declare to the living, in spite of all evidence, that they still belong amongst them. Their end attests to no meaning, brings with it no completion. These are not necessarily shadows who declare their revenge, but shadows who cry out beyond all vengeance. Whoever commits the imprudence of lending an ear to their call risks passing the rest of his life hearing their complaint.

We will call *essential mourning* the completion of mourning for essential spectres: that is to say the accomplishment of a living, rather than morbid, relation of the survivors to these terrible deaths. Essential mourning assumes the possibility of forming a vigilant bond with these departed which does not plunge us into the hopeless fear – itself mortifying – that we feel when faced with their end, but which, on the contrary, actively inserts their memory into the fabric of our existence. To accomplish essential mourning would mean: to live with essential spectres, thereby no longer to die with them. To make these spectres live rather than becoming, in hearing their voices, the mere shadow of a living being. The question which poses itself to us is thus the following: *is essential mourning possible – and if so, under what conditions*?

Is it possible, after a twentieth century whose history was dominated by odious deaths, to live a non-morbid relation with the departed, for the most part unknown to us, and yet still too close for our lives not to be secretly gnawed away at by them? At first glance, we seem to find ourselves constrained to respond in the negative. For this essential mourning seems impossible to envisage if it is referred to the general alternative of which the relation to the departed seems to admit. This alternative can be stated, summarily, in very simple terms: either God exists, or he doesn't. Or more generally: either a merciful spirit, transcending humanity, is at work in the world and its beyond, bringing justice for the departed; or such a transcendent principle is absent. Now, it becomes rapidly apparent that neither of these two options – let's call them for convenience religious or atheistic, however innumerable the ways in which they can be configured – allows the requisite mourning to take place. To say that God exists, or that he does not – whatever is thought through these two statements, both are paths to despair when confronted with spectres. To demonstrate this, let us directly exhibit, in the form of 'cases for the defence', what appear to us to be the strongest responses of each position to the challenge of such a mourning.

Take the following religious apology: 'I might hope to come to terms with my own death, but not that of terrible deaths. It is terror in confronting these past deaths, irremediably past, not my coming end, which makes me believe in God. Certainly, if my disappearance, by some chance, should be terrible, then I shall die hoping for myself what I hope for spectres. But I myself am but a spectre in waiting. I can be Sadducean for myself, and for others, but I will always be Pharisean for spectres. Or again: I might be rigorously atheist for myself, might refuse to believe in immortality for myself, but I could never do so for them: For the idea that all justice is impossible for the innumerable massed spectres of the past corrodes my very core, so that I can no longer bear with the living. Certainly, it is they, the living, who need help, not the dead; but I think that help to the living can only proceed given some hope for justice for the dead. The atheist might well deny it: for my part if I were to renounce this, I could not live. I must hope for something *for* the dead also, or else life is vain. This something is another life, another chance to live – to live something other than that death which was theirs.'

Now take the following, atheist response: 'You want to hope, you say, for something for the dead. Let's look closer, then, at what you promise them. You hope for justice in the next world: but in what would this consist? It would be a justice done under the auspices of a God who had himself allowed the worst acts to be committed, in the case of criminal deaths, or who himself had committed them, in the case of natural deaths. You call just, and even good, such a God. But what would you think of this: the promise to live eternally under the reign of a being called just and loving, who has, however, let men, women and children die in the worst circumstances, when he could have saved them without any difficulty whatsoever; who has even directly inflicted such sorrows – And even this, He says, as a mark of his infinite (and thus mysterious, unfathomable) love for the creatures he thus afflicts. To live under the reign of such a perverse being, who corrupts the most noble words – love, justice – with his odious practices: isn't this a good definition of hell? You say that in the dazzling presence of such a God, I will grasp the infinitely loving nature of his attitude to his creatures? You only succeed in exacerbating the nightmare you promise: for you suppose that this being has the power to spiritually transform me in such a radical fashion as to make me love He who allows such atrocities to occur, for having let those atrocities occur. This is a promise of a spiritual death infinitely worse than a merely bodily death: in the presence of God, I will cease to love the Good, for He would have the power to make me love Evil as if it were Good. If God exists, the exit of the dead is thus aggravated to infinity: their bodily death is redoubled in their spiritual death. To this hell you wish for them, I prefer, for them as for myself, nothingness, which will leave them in peace and conserve their dignity, rather than putting them at the mercy of the omnipotence of your pitiless Demiurge.'

We can see that each of these two positions is only supported by the weakness of the other: the atheist is atheist because religion promises a fearful God; the believer anchors his faith in the refusal of a life devastated by the despair of terrible deaths. Each masks his specific despair by exhibiting his avoidance of the other's despair. Thus the dilemma is as follows: either to despair of another life for the dead, or to despair of a God who has let such deaths take place.

We will call *spectral dilemma* the aporetic alternative of atheism and religion when confronted with the mourning of essential spectres.[3] In this aporetic alternative, we oscillate between the absurdity of a life without God, and the mystery of a God who calls 'love' his *laissez-faire* and production of extreme evil: the double form of a failure to accomplish essential mourning. On the contrary, we will call a *resolution* of the spectral dilemma a position which would be neither religious nor atheist, and which, because of this, would manage to extract itself from the double despair inherent to their alternative: despairing at the belief in justice for the dead, or believing despairingly in a God without justice. Our question concerning the possibility of essential mourning can be reformulated as follows: *Under what conditions could we hope to resolve the spectral dilemma*? How to think a bond between the living and dead which extracts itself from the twofold distress of the atheist and the religious believer?

---

[3] I have called 'religious' every position which brings together the thesis of a life beyond the grave with the existence of a personal God; 'atheistic' every position

To sketch a possible response to this question, we must proceed in the following fashion: we must exhibit the conditions of a solution to the dilemma, and evaluate the theoretical legitimacy of the latter along with its credibility. We do not exclude, of course, the possibility that this solution might eventually turn out to be illusory, and that we might have in the end to renounce extracting ourselves from the atheo-religious alternative. But this potential renunciation must proceed only from the precise examination of the solution. Not being able to present the

---

which recuses both of these theses. One might certainly conceive of positions which derogate from this convenient classification: Sadduceanism, evoked above, conjugates the belief in a personal God with the refusal of immortality; Spinozism, on the other hand, conjugates the recusal of a personal God with the thesis of a possible immortality. However, such positions do not change the essential point of the analysis: the incapacity of the principal systems of representation to resolve the spectral dilemma. In the case of Sadduceanism, I add to the despair of an evil God the despair of the non-resurrection of the dead; in the case of Spinozism, I must renounce all hope of a happy immortality for those who perished too soon to accede to wisdom, and accommodate myself to the pitiless necessity which presides over this type of destiny.

latter in its totality, we will content ourselves here with commencing its exposition.

2. CONDITIONS FOR THE RESOLUTION OF THE DILEMMA: THE DIVINE INEXISTENCE

Let us begin by exposing what we shall call the 'formal' conditions for a resolution of the dilemma. These conditions constitute at once the irreducibly legitimate part of the two preceding positions – atheistic and religious – and the source of the aporia. Each of these positions of the dilemma exhibits, we believe, an indispensable element of essential mourning:

- the religious position establishes that mourning is not possible unless we can hope for the dead something other than their death. The spectres will not pass over to the other world until the day we might hope to see them rejoin ours.
- The atheistic position establishes that the existence of God is an insurmountable obstacle to the elaboration of such despair, for only a perverse God could permit terrible deaths, and only an even more perverse God could make himself loved for doing so.

The aporia stems from the fact that these two conditions, equally indispensable, appear incompatible. There is only one way, then, to lift this impasse: we must prove that the incompatibility between these conditions is only apparent, and that there exists a third option, neither religious nor atheistic, capable of coherently combining the two elements of the response. From this point on, our path is clear: *resolving the dilemma comes down to making thinkable the statement* *conjugating the possible resurrection of the dead* – the religious condition of the resolution – *and the inexistence of God* – the atheistic condition of the resolution. These two elements will be synthesised in the following statement, which will occupy our attention from now on:

God no longer exists.

This statement formulates a thesis which we will call the thesis of *divine inexistence*, an expression that must be understood in the twofold sense that permits its equivocity. Firstly, in an immediate fashion, the divine inexistence signifies *the inexistence of the religious God*, but also the metaphysical God, supposed actually existent as Creator or Principle of the world. But the divine inexistence also signifies *the divine character of inexistence*: in other words, the fact that what remains still in a virtual state in present reality harbours the possibility of a God still to come, become innocent of the disasters of the world, and in which one might anticipate the power to accord to spectres something other than their death.

The position of the divine inexistence allows us to grasp the source of the apparent insolubility of the spectral dilemma. The latter comes from the fact that atheism and religion seem to constitute an alternative exhausting all the possibilities: either God exists, or he does not. But the two theses are in truth stronger than these factual statements: for their sense lies in the supposedly *necessary* character of either the inexistence or the existence of God. To be atheist is not simply to maintain that God does not exist, but also that he could not exist; to be a believer is to have faith in the essential existence of God. We now see that the thesis of the divine inexistence must, to gain ground against such an alternative, shift the battle to the terrain of modalities:

It is a question of maintaining that *God is possible* – not in a subjective and synchronous sense (in the sense that I maintain that it is possible that God currently exists), but in an objective future sense (where I maintain that God could really come about in the future). At stake is the unknotting of the atheo-religious link between God and necessity (God must or must not exist) and its reattachment to the virtual (God could exist).

The question then takes on a greater precision: resolving the spectral dilemma comes down to exhibiting the exact sense of the divine inexistence, at the same time as establishing that one can legitimately adhere to it.

The thesis – God no longer exists – can be decomposed according to two poles of signification which must then be studied consecutively:

1. What must be signified by a 'no longer', in order for a god to be thought as one of its eventualities? Such an examination comes down to thinking the signification of a time compatible with essential mourning: What is time, if it contains the divine as one of its virtualities, and what could legitimate our belief in the effectivity of the latter?
2. What does the signifier 'god' really mean once the latter is no longer posited as existing – as possible and to come, but no longer as actual and necessary? Such an examination would necessitate, notably, an elaboration of the elements of a discourse on the divine distinct from all theology founded on the thesis of an eternal God.

Within the confines of the present article we can only broach the first point. We will thus agree here to understand by ‘god’ the minimal sense required for an essential mourning to be envisaged: the emergence of a regime of existence in which, for the spectres, something begins other than their death.

3. SPECULATIVE TREATMENT OF HUME’S PROBLEM

What would a time capable of divine emergence be? And what could make us decide to adhere to the idea of such a time, knowing that our all-too-evident desire to believe, far from rendering the task easier for us, can only increase our suspicion in regard to every plea which flatters our hopes?

Before entering into the heart of the subject, let us begin by distinguishing the so-called ‘occult’ senses of the divine inexistence, that is to say those which rest upon the thesis that a hidden law exists, unknown for the moment, but capable of being at the origin of a redemption to come. This thesis comes down to an atheistic or religious interpretation of the divine inexistence, depending on whether it will be a question of founding the hope of rebirth on the Promethean mastery of death by a future humanity supposed technically capable of effectuating it; or a question of maintaining that a necessary process of divinisation of the world is already secretly in progress, which will culminate in universal justice for the living and the dead alike. In both cases, one maintains that an occult law exists upon which all hopes must rest: a natural law not yet known, of the resurrection of bodies, a providential law of progressive emergence of the divine – indemonstrable, even fantastic, theses, incapable in any case of supporting any serious hope.

But as soon as we prohibit ourselves any such path, we must say of the sought-after God not only that it must be posited as inexistent and possible, but also that it can only be conceived as *contingent* and *unmasterable*. This God, in fact, cannot be posited except as contingent, in the sense that, if its thinkability supposes that nothing prohibits its advent, inversely, no destinal law can be supposed to guarantee its emergence, for such a supposition is still theoretically exorbitant. It must be able to be, but nothing can be thought that constrains it to be. And this God can only be thought as unmasterable in its advent, in the sense that it must exceed all phantasmatic hopes of absolute domination of nature on the part of man. Neither Prometheanism of death vanquished, nor providentialism of a god to come – which are just exacerbated versions of atheism and religion confronted with the spectral dilemma – can found the hope of a solution.

Taking as granted the following hypotheses:

1. The laws of nature do not allow us to hold out any serious hope of a future rebirth of the departed.
2. Neither is there any hope of a transcendent Order of laws of nature, a bringer of justice for living and dead, whether actually at work, or in the course of emerging.

What outcome remains to us? It suffices, in response to this question, to determine what it is in such hypotheses that constitutes an obstacle to essential mourning: What seems to prohibit any resolution of the spectral dilemma, once I renounce the idea that a law exists, either natural or supernatural, capable of realising my hopes? The response is obvious: If I admit that there only exist natural laws incapable of resolving my dilemma, then this dilemma is insoluble, in so far as – but only in so far as – I admit also *the necessity of the laws of nature*. It is not the incompatibility between the laws of nature and the divine which prevents essential mourning: it is the belief in the necessity of such laws. And it is indeed this modal thesis which founds the atheistic belief in the impossibility of the existence of God, as of any event contradicting the attested constants.

The first question we must treat is thus as follows: what founds my adhesion to the necessity of laws, and thereby my refusal of any possible event's contradicting them? Now, this problem is well-known since it is precisely *the question posed by Hume concerning the rational justification of our belief in causal necessity*. We are consequently confronted once more by this question, but – let us note well, for this is the speculative interest of the matter – we must tackle it 'backwards' in relation to its traditional treatment.

Let us explain. The usual way of posing the question of causal necessity proceeds with the interrogation as formulated by Hume himself, and which can be stated as follows: it being understood that we believe in the necessity of laws, can this belief be founded in reason, so as to guarantee that laws will be in the future what they are today, all other circumstances being equal? The aporia encountered by Hume consists in the fact that neither logic nor experience are able to offer any such justification. For, on one hand, there is nothing contradictory in the observable constants being modified in the future; and, on the other, experience teaches us only about the present and the past, not the future. So that the supposed necessity of natural laws becomes an enigma since the Principle of Sufficient Reason cannot be effectively applied to it: We cannot rationally discover any reason why laws should be so rather than otherwise, that is to say why they should remain in their current state rather than being arbitrarily modified from one moment to the next.

Now, our perspective is the inverse of Hume's: for we propose on the contrary to start out from the *effective possibility* that natural laws might break down without reason, in favour of an eventality incompatible with them. For we pose the following question: since Hume has convinced us that we could *a priori* (that is to say without contradiction) conceive a chaotic modification of natural laws, why not have confidence in the power of thought, which invites us to posit the *contingency* of the laws of nature, rather than in experience, in which alone the presentation of the apparent fixity of observable constants finds its source? Why extrapolate the empirical fixity of laws into a belief in their necessity, rather than adhering to the intellection of a radical Chaos which Hume has masterfully, if implicitly, revealed to us? Why not, in other words, *absolutise* the failure of the Principle of Sufficient Reason, by maintaining that the meaning of that absence of reason for laws which we run up against in the Humean problem is not an incapacity of thought to discover such reasons, but a capacity of thought to intuit *a priori*, in the real itself, the effective absence of the reason of things as laws, and the possibility of their being modified at any moment? It would be a question of making of contingency the absolute property of every being, laws as well as things – a property which a redefined reason, *a reason emancipated from the Principle of Sufficient Reason*, would take as its task to conceive and to describe. Thus the idea presents itself of an *inverted*, rather than a *reversed* Platonism, a Platonism which would maintain that thought must free itself from the fascination for the phenomenal fixity of laws, so as to accede to a purely intelligible Chaos capable of destroying and of producing, without reason, things and the laws which they obey.

Does this mean that we will have resolved Hume's problem when we have posited the contingency of laws rather than their necessity? No, indeed, for we are then confronted by another problem, in the form of an objection expressing the reason why our thesis does not appear credible, namely: If laws could be modified without reason at any moment, it would be *extraordinarily improbable* if this possibility were never to manifest itself. And in truth, if matter could incessantly, in the least of its parts, follow innumerable different laws, the disorder would be such that there would not even be manifestation. This argument, as we know, is the very core of Kant's transcendental deduction: the contingency of laws is incompatible with the constitutive stability of representation. But our task is more precise now: to resolve the reformulated Humean problem, *we must refute such an inference, from the contingency of laws to a frequent, even frenetic, disorder,* whether *of matter* or of representation; we must establish that the manifest stability of laws does not demand that we maintain their necessity. Such is the first problem – which is far from being the last – that the spectral dilemma obliges us to resolve if we would recuse the impossibility of a counter-natural event coming to pass. From this point on, God must be thought as *the contingent, but eternally possible, effect of a Chaos unsubordinated to any law*.

Let us agree to call *speculative* all philosophies which accord to thought the capacity to accede to an absolute, and *metaphysical* all philosophies which ground themselves on a modality of the Principle of Sufficient Reason to accede to the absolute. All metaphysics, according to this reading, cannot but be speculative; however, not all speculation is necessarily fated to be metaphysical. For speculation which founded itself on the radical *falsity* of the Principle of Sufficient Reason would describe an absolute which would not constrain things to being thus rather than otherwise, but which would constrain them to being able not to be how they are. We can therefore formulate the conclusion at which we wished to arrive at, namely that *the existential resolution of the spectral dilemma passes by way of the speculative, but non-metaphysical, resolution of Hume's problem*.

* * *

A few words, to conclude, on the inexistent god. How – according to what principles of investigation – might one attempt to designate its nature, once the latter is defined as a contingent effect of Chaos? On this point, we must agree to pose again, outside the transcendental field, a Kantian-style question: What am I permitted to hope for, now that I can hope? What is a god which would be once more desirable, lovable, worthy of imitation? If one supposes granted the real eventuality of emergences in rupture with the present laws of nature, what will be the most singular possible divinity, the most interesting, the most 'noble' in a sense (paradoxically) close to Nietzsche's? Must this future and immanent god be personal, or consist in a 'harmony', a becalmed community of living, of dead, and of reborn? We believe that precise responses to these questions can be envisaged, and that they determine an original regime of thought, in rupture with both atheism and theology: a *divinology*, yet to be constituted, through which will be fabricated, perhaps, new links between men and those who haunt them.

Horror Temporis

Benjamin Noys

In his 'Notes on Writing Weird Fiction' (1937) Lovecraft wrote that time played such a large part in his fiction because he found it 'the most profoundly dramatic and grimly terrible thing in the universe'.[1] On the one hand, the horror of time is not simply the trifling matter of individual human finitude, but rather the recognition of scientific statements concerning cosmic timescales that precede and exceed the existence of humanity and life itself. Unlike Engels, who hoped against hope for future relief from the second law of thermodynamics,[2] Lovecraft only foresaw future extinction.

[2] As Engels puts it, in the vein of William Hope Hodgson's *The Night Land* (1912):

> Millions of years may elapse, hundreds of thousands of generations be born and die, but inexorably the time will come when the declining warmth of the sun will no longer suffice to melt the ice thrusting itself forward from the poles; when the human race, crowding more and more about the equator, will finally no longer

A science that produces time as indifferent to humanity is thus the source of the *horror temporis*. On the other hand, he writes that his stories are concerned with achieving the 'suspension or violation' of natural laws in order to probe 'the infinite cosmic spaces beyond the radius of our sight and analysis.' This suspension seems to promise an oneiric mysticism in the Dunsanian vein that escapes 'the prison-house of the known' into the 'enchanted lands of incredible adventures and infinite possibilities'. Thus, we seem to be left with the paradox of a horror based on science that threatens to proceed through an insipid anti-scientific mysticism. But Lovecraft's actual solution, at least in his great texts, was more inventive: the suspension of natural laws would produce a new materialism which liberates us into the experience of the horror of time in its subtraction from any law and any relation.[3]

> find even there enough heat for life; when gradually even the last trace of organic life will vanish; and the earth, an extinct frozen globe like the moon, will circle in deepest darkness and in an ever narrower orbit about the equally extinct sun, and at last fall into it. Other planets will have preceded it, others will follow it; instead of the bright, warm solar system with its harmonious arrangement of members, only a cold, dead sphere will still pursue its lonely path through universal space. And what will happen to our solar system will happen sooner or later to all the other systems of our island universe; it will happen to all the other innumerable island universes, even to those the light of which will never reach the earth while there is a living human eye to receive it.
>
> And when such a solar system has completed its life history and succumbs to the fate of all that is finite, death, what then? Will the sun's corpse roll on for all eternity through infinite space, and all the once infinitely diverse, differentiated natural forces pass for ever into one single form of motion, attraction? 'Or' - as Secchi asks – 'do forces exist in nature which can re-convert the dead system into its original state of an incandescent nebula and re-awake it to new life? We do not know'.

Dialectics of Nature (1883) 'Introduction'. At http://www.marxists.org/archive/marx/works/1883/don/ch01.htm

[3] This obviously indexes the work of Quentin Meillassoux, in particular his paper 'Subtraction and Contraction', **Collapse** III (2007): 63-107. Through a reading of

The question is of 'the mode of manifestation' of this operation, which Lovecraft regards as requiring an 'object embodying the horror and phenomena observed'. His fiction works through images of these objects, through the domain of the imaginary, but only through the impasse where the imaginary touches upon the real. If scientific laws provide him with the final regulative guarantee of consistency then his fiction probes the inconsistency of 'shattered natural law' and the inconsistency of the object. To achieve this effect requires the gradual purification of the object from the regulation of representation. In the case of time this process can be traced in the last of his great texts: 'The Shadow Out of Time' (1936).[4] Here it is a matter of what kind of object constitutes the shadow that falls from the outside – not a mystical outside of completed alterity, the *tout Autre*, but a material 'outside' which does not respond to the effect of law or to any correlation or relation to humanity.

That outside is named in the opening of the story as the 'seething vortex of time'. The preliminary image of the vortex obviously derives from Poe and his use of the vortex in the form of a whirlpool in a number of his stories.

Bergson and Deleuze Meillassoux approaches a subtractive thinking of matter as 'an *infinite madness*' in which,

> we would have to conceive what our life would be if all the movements of the earth, all the noises of the earth, all the smells, the tastes, all the light – of the earth and of elsewhere, came to us in a moment, in an instant – like an atrocious screaming tumult of all things, traversing us continuously and instantaneously. (104)

Can we suggest that this is often the state of the Lovecraftian hero at the end of many of the stories? Can we also suggest, alongside Meillassoux, that this indicates the ruination of philosophy in 'absolute communication', the point at which Lovecraft indicates the collapse of the philosophical in chaos?

[4] H. P. Lovecraft 'The Shadow Out of Time' in H. P. Lovecraft, *The H. P. Lovecraft Omnibus 3: The Haunter of the Dark and Other Tales* (London: Panther Books, 1985), 464-544.

Take, for example, this description from 'A Descent into the Maelström' (1841): 'the interior surface of a funnel vast in circumference, prodigious in depth, and whose perfectly smooth sides might have been mistaken for ebony, but for the bewildering rapidity with which they spun around.' In this case we have an image taken from nature that embodies a turbulent flow in excess of mechanistic materialism. This is nature itself as what Lacan would call *antiphysis* – a 'rotten', chaotic, fractured nature. Lovecraft radicalises this impasse of nature by not containing it within nature as an emergent fracture. Instead, as the 'seething vortex of time', the vortex becomes the chaotic space of the emergence of nature itself: the Outside. We no longer have a confined phenomena, a hole in the imaginary through which the real surges. Lacan would state that while the real does not lack anything, it is full of holes and one can even make a vacuum in it.

The mode of manifestation proceeds through a number of supplementary objects of horror that embody the shadow that falls from outside. In the first instance the shadow falls on the story's narrator, Nathaniel Peaslee, when he suffers from a strange experience of amnesia between 1908 and 1913 (the same period as Lovecraft's own nervous breakdown). As the narrative unfolds it soon becomes evident that Peaslee had his mind exchanged with a member of the Great Race – alien beings that lived on the earth fifty million years before mankind and that have mastered the secret of time. When Peaslee returns to his body he finds that 'my conception of *time* – my ability to distinguish between consecutiveness and simultaneousness – seemed subtly disordered'. This disorder of time can be explained as a result of the transference or interference by the Great Race, but also by the impact of his realisation that for these alien creatures 'there was no such thing as time in its humanly accepted sense.' During the period in which Lovecraft was writing, Heidegger and Bergson were trying to produce new concepts of time that would correlate, in however attenuated a fashion, with the human experience of time. What Lovecraft suggests is the detachment of time from any relation to humanity – proceeding without philosophy towards the real.
